chiefly occupied with studies concerning its ancient history, but was at first disappointed by the degeneracy of the people and the meagreness of its monuments, and was harassed by the limitations in the use of the public libraries. He did not receive his final instructions as ambassador till he had been at his post 4 years, and the negotiations with the papal court were completed by Hardenberg in person in 1821. But the services of Niebuhr in the entire arrangement of the preliminaries were acknowledged by the court, and he was rewarded by the king of Prussia with the order of the red eagle, and by the emperor of Austria with the Leopold order of knighthood. In 1821 Bunsen became secretary of the legation, and Niebuhr was engaged in planning the work on Roman topography, which he subsequently aided Bunsen, Platner, and others in preparing. In 1822 he asked for and obtained a temporary release from his duties, which was afterward made final, and resided chiefly in Berlin and Bonn till in 1824 he became adjunct professor of ancient history in the university recently established in the latter city. In 1824 he lectured on the history of Greece after the battle of Chæroneia, on Roman antiquities in 1825, on ancient history in general in 1826, on ancient geography and ethnology in 1827, on imperial Rome in 1828 and 1829, and on Roman history in 1830. He instituted in 1827 the *Rheinisches Museum*, consisting of short philological essays by eminent scholars; superintended the republication of the *Corpus Scriptorum Historiæ Byzantinæ*, to which he furnished an edition of Agathias; and was especially occupied with revising and correcting his great work on the history of Rome, the first volume of the new edition of which appeared in 1827. "I do not hesitate to say," he wrote, "that the discovery of no ancient historian could have taught the world so much as my work; and that all that may hereafter come to light from ancient and uncorrupted sources will only tend to confirm or develop the principles I have advanced." The work attracted general attention, and gave a new impulse to the investigation of classical antiquity. In the winter of 1829-'30 his house was burned, and with it nearly all the MSS. of his second volume, which, however, he was able to prepare again for the press within a year. During his residence at Bonn he was systematically and happily occupied, and, though interested in public events, devoted himself exclusively to what he regarded as the great labor of his life. The French revolution of July, 1830, caused him the deepest anxiety, and he foreboded the worst consequences from the revival of popular sovereignty. A cold which he caught on one of his frequent visits to the news rooms resulted in inflammation of the lungs, which terminated fatally after a week's illness. Niebuhr was personally remarkable for amiability, earnestness, and integrity, combined with a wayward, impatient, and impracticable temper. He cherished the hab-

its of a retired and unassuming scholar after having received distinguished honors for public services, and while recognized as the first philologist of Europe. He had married a second time before his visit to Rome, where his son Marcus was born, whom he educated with peculiar care, and with the determination to make him "believe in the letter of the Old and New Testaments." "I shall nurture in him," he said, "from his infancy a firm faith in all I have lost or feel uncertain about." This son attained to high office in the Prussian civil service, was an enemy of liberal ideas, and died Sept. 1, 1860.—The principal monument of the genius of Niebuhr is his *Römische Geschichte* (2d. ed. 1827-'42; translated into English by J. O. Hare and Connop Thirlwall), which has been called the most original historical work of the present age. It was a reconstruction of Roman history, a development of historical materials from the early myths and legends. Its aim to reproduce the fabric of history from scattered fragments, to extract truth and certainty out of traditional narratives, together with the erudition, sagacity, and power of imagination which it displayed, excited the enthusiasm of intelligent readers. He sometimes gave the name of divination to the combinations by which he reached the basis of historical truth. In England his theories were generally accepted by scholars, and Dr. Arnold professed never to venture to differ from him except when he manifestly had evidence that had not occurred to him. Macaulay also favored his theory of the presumed derivation of early Roman history from national ballads, which has since been generally abandoned in Germany, and which Sir G. Cornewall Lewis has proved to rest on insufficient positive evidence. Another view which he brought into prominence was that the patricians and plebeians were respectively a conquering and a conquered race, with different languages, feelings, and habits, yet gradually coalescing into a single body politic. Three series of his lectures have been published since his death in both German and English, respectively on Roman history, on ancient ethnography and geography, and on ancient history. They were edited by his son Marcus and Dr. Ischer, and have been translated by Dr. L. Schmitz (8 vols. 8vo.). His opinion that the mediæval municipal institutions of Italy were derived from the Romans, and not from the northern invaders, has been generally rejected. It is remarkable that he did nothing to elucidate the monetary system of the Romans. His principal minor writings were collected in his *Kleine historische und philologische Schriften* (2 vols., Bonn, 1828-'43), and his *Nachgelassene Schriften nicht philologischen Inhalts* (Hamburg, 1842). In 1838 appeared his *Lebensnachrichten* (2 vols., Hamburg), consisting largely of his correspondence, abridged and translated into English by Miss Winkworth, with important additions by Bunsen, Brandis, and others (3 vols., London, 1852).

NIEBUHR, KARSTEN, a German traveller, born in Lüdingwort, Lauenburg, March 17, 1788, died in Meldorf, Holstein, April 26, 1815. He was the son of a small landed proprietor, and both his parents died when he was very young, leaving him poor, though not destitute. Having chosen the profession of land surveyor, he went to Hamburg, where he studied for two years, and then spent a year at Göttingen, chiefly devoted to the study of mathematics. About this time Count Bernstorff, the minister of Frederic V. of Denmark, undertook to carry out the suggestion of Michaelis to send a scientific expedition to the East, for the purpose of illustrating Old Testament geography and natural history, and Prof. Kästner of Göttingen recommended Niebuhr as mathematician. He spent two years in preparation, practising astronomical observations, and studying Arabic under Michaelis. He refused the title of professor, thinking his qualifications undeserving that distinction, but accompanied the expedition as mathematician and treasurer, with the rank of lieutenant of engineers. The expedition sailed in Jan. 1761, and after touching at Constantinople proceeded to Alexandria, and ascended the Nile, reaching Cairo Nov. 10. After making an examination of the pyramids and other antiquities of lower Egypt, they went with a caravan to Suez, whence Niebuhr made an excursion to Mount Sinai. In Oct. 1762, they took ship from Suez to Lobeia, and thence travelled by land to Mocha, where Von Haven, the philologist, died in May, 1763; and on their journey to Sana, the capital of Yemen, they lost the naturalist Forskål. They were well received at Sana, but dreading the climate they resolved to abandon further exploration of Yemen, and returned to Mocha, where the whole party were taken sick while waiting for a ship to convey them to India. They at length obtained passage in a Scotch ship to Bombay. Baurenfeind, the draughtsman, died on the voyage, and Cramer, the physician, the last of Niebuhr's companions, expired soon after their arrival. Niebuhr himself was only saved by his prudence and care of his diet. He remained 14 months in Bombay arranging his journal, and then turned homeward, visiting Muscat, Bushire, Shiraz, and the ruins of Persepolis, ascending the river Euphrates to the ruins of Babylon, and thence going to Bagdad and to Mosul, where he joined a caravan going to Aleppo. Having received permission from the Danish government to prolong his travels, he passed over to Cyprus, and returning made a tour in Palestine, went with a caravan across Mt. Taurus to Brousa in Asia Minor, arrived at Constantinople in Feb. 1767, and finally reached Copenhagen in November of the same year. The whole expense of the expedition, through his prudent management, was only \$20,000. He was received in Denmark with marked honor. He published the first fruits of the expedition in German under the title of "Description of Arabia" (Copenhagen,

1779), the government defraying the expense of the illustrations. In 1774-'8 he continued his narrative by publishing his "Travels in Arabia and the Neighboring Countries" (3 vols., Copenhagen). The 8d volume was not published till after his death in 1837; it bore the same title as the preceding, and contained an account of his homeward journey, through Aleppo, Jaffa, Jerusalem, and Constantinople, with brief notices of Bulgaria, Wallachia, Poland, and Germany. He contributed to a German periodical a paper on the "Interior of Africa," and one on the "Political and Military State of the Turkish Empire." He also edited Forskal's papers, *Descriptiones Animalium*, and *Flora Egyptiaco-Arabica* (4to., 1775). The works of Niebuhr contained much new information in regard to the East, and were written in such a clear and unaffected style that they were regarded as almost classical. The Danish government rewarded his services with the cross of Dannebrog; in 1802 he was made a member of the French institute; and in addition to other honors, the title of councillor of state was conferred on him by Hanover in 1806. From 1768 to 1778 he resided at Copenhagen as a captain of engineers, and in the latter year received a civil appointment at Meldorf. Toward the close of his life he became blind. His son, the historian, who wrote his life (Kiel, 1817), says of him: "He was, and remained through life, a genuine peasant, with all the virtues and also the little failings of his order. He was certainly self-willed and obstinate. His character was perfectly irreproachable, and his morals were extremely strict and pure."

NIEL, ADOLPHE, a French general, born in Muret, Pyrénées, Oct. 4, 1802. He entered the polytechnic school of Paris in 1821, and the military academy of Metz in 1828, and commenced his military career in 1825 as a 2d lieutenant of engineers. In 1836-'7 he distinguished himself in the expedition against Constantine in Algeria, and was promoted, Oct. 25, 1837, to command the corps of engineers in that province. On his return to France he gained distinction by his labors as military engineer under the orders of the ministry of war, and was appointed colonel in 1846. In 1849 he accompanied Gen. Vaillant in the expedition to Rome. He became general of division in 1853, commanded in 1854 the siege operations against Bomarsund, and in 1855 was appointed adjutant of Napoleon III., and was employed in the siege of Sebastopol. In 1857 he became a member of the French senate. In 1859 he took a prominent part in the Italian campaign, and decided by the skilful operations of the artillery under his command the victory of Solferino (June 24), after which he was made a marshal of France.

NIEMCEWICZ, JULIAN URSIN, a Polish author and statesman, born in Skoki, Lithuania, in 1787, died in Paris, May 21, 1841. He was educated in the military academy of Warsaw,

and became an adjutant of Czartoryski; but he left the military service in 1788 with the rank of major, and served from 1788 to 1792 in the constituent Polish diet as a deputy of Lithuania, being one of the most active members of the liberal reform party, the leading ideas of which he strove to make popular by his writings in prose and verse. On the outbreak of the revolution of 1794 he fought on the side of Kosciuszko, and afterward shared his imprisonment in Russia, and accompanied him in 1797 to America, where he married an American lady. After Napoleon's invasion of Poland he returned to Warsaw (1807), and was appointed secretary of the senate; subsequently, after the annexation of his native country to Russia, he became president of the committee on the new constitution, in the authorship of which he took a prominent part. During the revolution of 1830 he was a member of the administrative council, and exercised great influence in the senate, where in his capacity of secretary he drew up the resolution which expelled the Romanoff family from the throne of Poland. Shortly before the fall of Warsaw he left for Paris, where he spent the rest of his life. His eulogy on Kosciuszko is considered as a masterpiece, and he is held in high regard as one of the great Polish patriots, although his preference for a constitutional monarchy injured his popularity among the democrats. His principal works are his *Spiewy historyczne*, or "Historical Songs of the Poles," with historical sketches (Warsaw, 1816), which were set to music and attained immense popularity; the history of the "Reign of Sigismund III." (1819); and his brilliant historical novel, "John of Tenczyn" (1825). In his "Leb and Sarah, or Letters of Polish Jews," he illustrates the peculiar moral and intellectual condition of the Jewish population of Poland. His fables and tales in the style of La Fontaine are admirable. A complete edition of his poetical works was published in 12 vols. in Leipzig in 1840, but his other works have not yet been collected. He also left many posthumous writings, of which *Notes sur ma captivité à St. Pétersbourg* was published in Paris in 1848.

NIEMEN, a river of Europe, rising in the Russian government of Minsk, and flowing W. to the town of Grodno, partly separating the governments of Wilna and Grodno, then N. between those of Wilna and Augustowo to Kovno, and finally W. between Augustowo and Kovno, and thence through Prussia to the Curisches Haff, an arm of the Baltic. After entering Prussia it takes the name of Memel. About 8 m. below Tilsit it divides into two branches, one of which is called the Rust, and the other the Gilge. The delta which they form, called the island of Kaukehnen, is remarkable for its fertility. The chief tributaries of the Niemen are the Wilia, Joura, and Zelva. The principal towns on its banks are Grodno, Kovno, Tilsit, and Gilge. The entire length of this river is about 450 m., not more than 50 of

which are in Prussia. It is the main outlet for the products of the countries through which it flows. As the snows of the regions which it drains dissolve rapidly on the approach of summer, the Niemen frequently rises 20 or 30 feet above its ordinary level, causing great devastation. It is connected by the Oginski canal with the Dnieper and the Black sea.

NIEMEYER, AUGUST HERMANN, a German theologian and author, born in Halle, Sept. 11, 1754, died there, July 7, 1828. He studied theology at the university of Halle, where in 1780 he was appointed professor, and in 1784 he became inspector of the royal *Pädagogium*. In 1808 he became perpetual rector of the university. Napoleon abolished the institution in 1818, but on its restoration he was reappointed. The 50th anniversary of his reception of the degree of M.A. was celebrated at Halle, April 18, 1827, on which occasion the king granted his petition for an appropriation for a new university building. He was a popular writer on practical religion and education.

NIEPOE, JOSEPH NIEPCE, a French chemist, one of the inventors of photography, born in Châlons-sur-Saône in 1769, died in 1833. After serving in the army for one year, he was obliged by severe illness to resign, and was appointed civil administrator of the district of Nice, which post he held from 1794 to 1801. Retiring then to private life, he devoted himself to the study of mechanics and chemistry, and as early as 1818 made a series of investigations, which he styled "heliographic researches," to find the means of fixing images upon metallic plates by the agency of light. In 1824 he had partially succeeded in producing pictures, first on tin and polished glass, then on copper, and finally on silver, the surface having in each case been covered with a thin film of bitumen; but the process was very slow. In the mean time Daguerre had been engaged upon the same problem, and in 1829 the two experimenters entered into a copartnership to improve the discovery, which, according to the terms of agreement, had been made by Niepce; but the latter died before it was perfected. —See *Histoire de la découverte improprement nommée daguerréotype*, by Isidore Niepce fils.

NIEPOE DE ST. VICTOR, OLAUDE MARIE FRANÇOIS, a French chemist and inventor, nephew of the preceding, born at St. Cyr, near Châlons-sur-Saône, July 26, 1805. He was educated in the military school of Saumur, and commissioned a sub-lieutenant in the 1st regiment of dragoons. While quartered at Montauban, he was led by accident to devote his attention to chemistry, with particular reference to the process of dyeing. An order having been issued by the minister of war that the facings, cuffs, and collars of a number of cavalry regiments should be changed from crimson and rose color to orange, Lieut. Niepce submitted a method for discharging the original color and substituting the desired tint at a cost of half a franc the uniform, or about one twelfth of

the original estimate. His method was examined and accepted, and a reward of 500 francs was bestowed upon him for saving the government an expenditure of 100,000 francs, with permission to exchange into the municipal guard of Paris, in order that he might more advantageously pursue his chemical studies. It was not however until April, 1845, 8 years afterward, that the promised appointment was bestowed. In the interval he devoted himself to experiments in photography, with a view of perfecting the process partially discovered by his uncle; and in 1847 the results of his labors were communicated to the academy of sciences in two papers, the first of which related chiefly to the reproduction of designs by the use of vapors of iodine, and the second, entitled *Premier mémoire de la photographie sur verre*, announced his method of obtaining images on glass plates coated with a film of starch, gelatine, or albumen. A second memoir, presented in the succeeding year, exhibited some important improvements in the process, which was soon after almost universally adopted by photographers. He pursued at the same time a contemporary course of experiments in producing photographic pictures in colors, and in 1851-'2 presented to the academy several memoirs on the subject. He succeeded in obtaining upon silvered plates, washed with chloride of copper, accurate representations of a variety of colored objects, but was unable to fix the tints, which gradually faded, and finally disappeared altogether. In 1853 he presented to the academy an account of his process of producing photographically engraved steel plates, called by him heliography, and which was in fact a development of an imperfectly described method practised by his uncle. He obtained the impression of the image upon a polished steel plate covered with a thin film of varnish, of which benzine was the chief ingredient; after which the picture was bit in with acid as in the process of etching. Many excellent impressions have been entirely produced by this process, although in general it is found expedient to retouch them with the burin. His promotion kept pace with his scientific discoveries, and, having reached the rank of *chef d'escadron*, he was in 1854 appointed by the emperor Napoleon commandant of the Louvre, a position enabling him to pursue his labors in photography at comparative leisure. In 1855 he published, under the title of *Recherches photographiques*, all the memoirs on photographic subjects presented by him to the academy, and in the following year produced a paper on the possibility of engraving photographically on glass as well as metal. He has also made photographic etchings on marble, and by filling the depressions with various colored acids has obtained effects equalling those of choice mosaics. He is constantly engaged in perfecting the various processes discovered by him, but refuses to secure his inventions by patent for his own benefit.

NIUWENTYT, BERNARDUS, a Dutch mathematician and philosopher, born in Westgraafdyk, North Holland, Aug. 10, 1654, died in Purmerend, May 30, 1718. He studied law, medicine, logic, philosophy, and mathematics, and, settling in the town of Purmerend, became famous as an orator, physician, and magistrate. His mathematical works enjoyed an ephemeral popularity in consequence of their attacks on the infinitesimal calculus. His most important production is his treatise on "The Right Use of contemplating the Works of the Creator" (Amsterdam, 1715). From this treatise Paley is supposed to have borrowed the substance of his essay on "Natural Theology." An English translation of Nieuwentyt's book, by Chamberlayne, appeared in London in 1718-'19, under the title of "The Religious Philosopher."

NIEVRE, a central department of France, comprising the old province of Nivernais, bounded N. by the department of Yonne, E. by Côte d'Or and Saône-et-Loire, S. by Saône-et-Loire and Allier, W. by Cher, and N. W. by Loiret; area, 2,632 sq. m.; pop. in 1856, 326,086. It is intersected from S. E. to N. W. by the mountains of Morvan, which divide the basin of the Seine from that of the Loire, and culminate in Mont Prenelay, 2,912 feet above the sea. The surface N. of this chain is an alternation of rugged hills and deep valleys; but in the S. lie extensive plains sloping gently to the Loire. The principal rivers are the Loire, Allier, Yonne, Aron, and Nièvre. The climate is mild but moist. The soil is not in general remarkably fertile. The quantity of wine made annually averages about 6,000,000 gallons. Mining, especially of iron and coal, is largely carried on. Woollen cloth, linen, and hardware are manufactured. Capital, Nevers.

NIGER, QUORRA, or KWORA, a river of central Africa, which falls into the gulf of Guinea by several mouths, between the bights of Benin and Biafra. The Niger is formed by two principal rivers, the Benoowe or Chadda (see BENOOWE) and the Joliba, the latter of which is the more western, and is believed to be the main stream. It rises in lat. 9° 25' N., long. 9° 45' W., in the mountains upon the borders of Liberia, about 200 m. from the sea, and for $\frac{2}{3}$ of its entire length pursues a general N. E. though very circuitous course toward the Sahara. Near Cabra, the port of Timbuctoo, it turns E. and afterward S. E., and near the Kong mountains, in lat. 7° 47' N., long. 7° 27' E., is joined by the Benoowe, from which point it flows S. S. W. and finally S. W. till it falls into the ocean after a course of about 2,500 m. For the first 70 m. it is called the Timbri; it afterward receives the name of Baba or Joliba, and below Timbuctoo is known as the Quorra. For rather more than 200 m. between Curuassa and Bammakoo the course of the river is unknown; but between the latter place, lat. 18° N., long. 5° 20' W., and Timbuctoo, lat. 18° N., long. 8° 40' W., it has been laid down by Mungo Park and Caillé. Mungo

Park was the first European traveller who reached its banks in the upper part of its course. In his first journey (1796) he traced it for about 160 m. between Bammakoo and Silla. He found its banks fertile and populous, and in the rainy season overflowed for a considerable distance back from the shore. In his second journey (1806) Mungo Park embarked at Sego, between Bammakoo and Silla, and descended the river more than 1,000 m. to Boussa, where he was killed. The loss of many of his papers deprived the world of the information which he had gathered, but Caillé has partly supplied the deficiency. He descended the river from Jennee to Timbuctoo, and found the country through which it flowed in some places well cultivated and populous. The boats which he saw trading on this part of the river were from 60 to 80 tons burden, and were worked without sails by a crew of about 20 men in each. S. of lat. 16° N. the Quorra flows through Lake Debo, which is of considerable length and about 10 m. wide. After passing this lake the country is better cultivated and more thickly inhabited, and a considerable traffic is carried on with Timbuctoo. It is stated by Dr. Barth, who visited Timbuctoo in 1853, that the river overflows the surrounding country, and that in consequence the climate in the neighborhood of that city, during the season of the inundation, is very unhealthy. Above Timbuctoo the river separates into two branches, which unite a little further down. Cabra, the port of Timbuctoo, is situated on the N. branch. Between Timbuctoo and Yaori the Quorra leaves the great plain of Soodan; and above the latter place it flows through the narrow country of Dindina, enclosed by mountains and inhabited by a tribe of Tuaricks, who are superior in industry and civilization to their neighbors. The river Rima, Sackatoo, or Zirmi joins the Quorra from the E., S. of the Dindina country; the town of Sackatoo is situated on it. There are several important places in this neighborhood, to which considerable quantities of American and British manufactures find their way. Dr. Barth states that the former are sent up the Quorra in American steamers, and the latter come across the desert in caravans from Tripoli and the Mediterranean coast. American commerce is said to be extending widely in these regions. The brothers Lander navigated the Niger from Yaori to its mouth. Between Yaori and lat. 7° it is only navigable during and after the rainy season. In this part of its course the Niger runs through a low valley in a mountainous country, and the banks are annually inundated, very fertile, and well peopled. Between lat. 7° and 8° the mountains in many places approach both sides of the river, and the valley is nowhere very wide nor thickly inhabited. Near lat. 6° the Niger leaves the mountain region and enters an alluvial plain, where it divides into numerous branches. This delta is mostly swampy, and covered with jungle,

with high forests in some places. The more elevated parts, however, are cultivated, and villages appear at intervals. The principal arm of the delta is called the Nun.—It is now generally admitted that the upper part of the Quorra, or modern Niger, is the same as the Niger of Ptolemy and Strabo. Pliny thought it was an affluent of the Nile, and the same opinion long continued to be held. Ptolemy describes its upper course with some accuracy, but he supposed it to be an interior river, which lost itself somewhere in the African sands without ever approaching the sea. Abulfeda, Edrisi, and Leo Africanus believed that it rose near the sources of the Nile and flowed westward. When the Portuguese explored the W. coast of Africa they discovered the rivers Senegal, Gambia, and Grande, each of which in succession they supposed to be the Niger, and explored to its source in the hope of reaching Timbuctoo. Even after the real direction of the Niger began to be suspected, it was supposed for some time to be identical with the Congo river, and Mungo Park explored it with this idea. It was not until the discoveries of Richard Lander, who in 1830 navigated the river from Yaori to the Atlantic, that the question was set at rest. The explorations of Dr. Barth are among the most valuable that have lately been made. (See BARTH, BENOOWE, CLAPPERTON, LANDER, PARK (Mungo), &c.)

NIGHT-BLOOMING CEREUS. See CEREUS.

NIGHT HAWK, a North American goat-sucker of the sub-family *caprimulginae* and genus *chordeiles* (Swains.). In the *C. Virginianus* (Swains.) the length is 9½ inches, and the extent of wings about 28½; the bill is very small and curved, with a wide gape furnished with a few very short hairs, and the tip hooked; the wings very long and pointed, the 2d quill the longest; the tail long, broad, and forked; tarsi short and partly feathered, and toes feeble; the head large and flat, the eyes and ears large, neck short, and body slender; the plumage is soft and blended. The male is greenish black above, slightly mottled on the head and back; wing coverts varied with grayish, and the scapulars with yellowish rufous; a white V-shaped mark on the throat, and terminal patch on the tail; a collar of pale rufous blotches, and grayish mottled on the breast; under parts transversely banded with rufous white and brown; quills brown; 5 outer primaries with a white blotch midway between the tip and carpal joint; the female has not the white patch on the tail, and that on the throat is mixed with reddish. The common name of this bird is ill-chosen, as it is not a hawk, nor does it fly by night; in cloudy weather it flies all day, and its favorite time is from an hour before sunset to dark; it passes the night on the ground or on a tree, while its allies the chuck-will's-widow and the whippoorwill are then most active and noisy. It is very generally distributed over North America, appearing in Louisiana on the way to the north and east

about April 1, in the middle states about May 1, in Maine about June, going even into New Brunswick and Nova Scotia, and returning to the south in autumn. The flight is rapid, light, graceful, and capable of long continuance; it is fond of skimming like a swallow over marshes in search of food; in its aerial evolutions it makes frequent and sudden turnings, ascending almost perpendicularly and descending with great impetuosity, like a hawk, uttering usually a squeaking cry. From the small size and backward position of the legs, it can hardly walk, or stand erect. It breeds from South Carolina to Maine; in the middle states it deposits 2 freckled eggs about May 20, on the bare ground, without any nest; both sexes assist in incubation, and the female adopts various devices to distract attention from her eggs or young. The food consists of insects, especially beetles, moths, caterpillars, crickets, and grasshoppers; the night hawk drinks while flying low over the water, in the manner of swallows. Their flesh is esteemed as food when they return from the north in autumn, as it is then fat and juicy.—Other species are the western night hawk (*C. Henryi*, Cassin), much resembling the last, if not a mere variety, from the Rocky mountains of New Mexico; and the Texas night hawk (*C. Texensis*, Lawr.), which is smaller, and has rounded rufous spots on both webs of the quills.

NIGHT HERON, the common name of the division *nycticoraceae* of the family *ardeidae* or herons. The common night heron of America is the *nycticorax naevius* (Bodd.), or *nyctiardea Gardeni* (Baird); the bill is 8½ inches long above, very stout, curved from the base, with emarginated tip and compressed grooved sides; wings long, the 2d and 3d quills longest; tail short and even, with 12 feathers; tarsi strong, as long as the middle toe, covered with small scales; toes long and slender, united at the base by a membrane, the outer the longest, and the hind one even with the others; claws moderate, slightly curved, and acute; the neck short, with a long occipital plume of 8 feathers, rolled together; body slender and compressed; lower fifth of tibia bare. The bill is black, the iris red, and the feet yellow; the head above and the middle of back steel green; wings and tail ashy blue; forehead, under parts, and occipital feathers white, passing into pale lilac on the sides and neck; the length is 25½ inches, the extent of wings about 43, and the weight nearly 2 lbs.; the adult female resembles the male, but the young are grayish brown above. It is distributed generally over the United States, residing permanently in the southern portion; in the eastern states it is called the "qua" bird from the noise which it makes. Going north in the spring, some get as far as Maine; at Hingham, Mass., and in the woods near Fresh pond, Cambridge, there used to be famous heronries, to which the birds returned year after year, until the persecutions of those in search of their young drove them

away entirely or into more inaccessible places. The nests are made of coarse sticks on bushes or trees, often overhanging the water, and are revisited and repaired annually; they congregate in large numbers in the breeding season, during which they lose their natural shyness; the eggs are usually 4, 2 by $1\frac{1}{4}$ inches, of a plain light sea green color and thin-shelled. By day they are harassed by crows, hawks, and vultures, and by raccoons and other animals at night. The young birds are as tender and juicy as pigeons, without the fishy taste of the adults, and are in great request for the table. They return to the south in autumn. The night heron generally remains on the low swampy lands near the coast, where it feeds upon fish, reptiles, crustaceans, water insects, leeches, and even mice and such other small animals as fall in its way. The flight is slow, steady, and long continued, with the head drawn in and the legs extended; on the ground it is very restless, and without the grace of the true herons.—The European night heron (*N. griseus*, Strickl.) is similar, but smaller, and the young have not the white spot at the apex of the quills seen in the American bird. Several other species occur in other parts of the world. The yellow-crowned night heron (*N. violaceus*, Bonap.), found in the southern Atlantic and gulf states and in South America, is a little smaller, with the neck and body grayish plumbeous, the head bluish black, the hood and a broad patch on the side of the head yellowish white, and the scapulars dusky with grayish plumbeous edgings and considerably elongated.

NIGHTINGALE (*lucinia philomela*, Bonap.; the *philomela* of the ancients and *rossignol* of the French), one of the finest of European singing birds, whose melody has been celebrated in prose and verse from time immemorial. The genus belongs to the sub-family of warblers, from which it differs principally in its more slender shape, and longer bill, tarsi, and tail; it comes near many of the smaller thrushes both in form and color, and in the character of the song. In this genus the bill is short and straight, with the culmen slightly curved, sides compressed, and tip emarginated; the gape without bristles; the wings moderate, with the 1st quill $\frac{1}{2}$ the length of the 2d, and the 3d the longest; the tail moderate, rounded at the sides; tarsi long and strong, covered in front with an entire scale; toes very long and slender, the outer longer than the inner and united at the base; hind toe long, with a curved claw. The length is $6\frac{1}{2}$ inches, the extent of wings $10\frac{1}{2}$, and the bill about $\frac{1}{2}$ inch. Though so fine a songster, the nightingale is very plainly colored; the upper parts are rich brown, with a reddish tinge on the back and tail; below grayish brown, with the throat and abdomen whitish; the female is like the male in color, and is nearly of the same size; there is considerable variation in the reddish and grayish tints, and in the occurrence of white feathers. They begin to appear in the middle of France

about the first week in April, and in England a week or 10 days later; the males arrive a few days before the females, travelling singly and at night; they get mated in about a week, and commence their nests on the ground in thickets; these are rudely made of leaves and grasses, and the 4 or 5 eggs, $\frac{1}{2}$ by $\frac{1}{4}$ of an inch, are of a pale brownish color, sometimes tinged with grayish blue, especially at the small end; both sexes incubate. It is a migratory bird, passing the winter in northern Africa, but in the summer found over the greater part of Europe, even to Sweden and temperate Russia; it is said not to be found in Great Britain north of the Tweed. They begin to sing when mated, and continue in full song till the young are hatched; the notes are most rich at the beginning of summer, and toward the end it becomes a single low croaking note. They are very shy, remaining concealed as much as possible among the foliage; they frequent woods, hedges, and thickets, feeding on insects and larvae, soft berries, and fruits; the flight is short, even, and swift, but not so rapid as that of the true warblers and flycatchers which seize insects on the wing. Though the song is heard at intervals during the day, it excites the greatest admiration on quiet evenings an hour or two after sunset; when the moon is nearly full and the weather is serene and still, it may be heard till midnight, and is then exceedingly pleasing. Virgil and other classical poets, from the melancholy character of part of its song, call it *miserabile carmen*; though it would seem an insult to modern poets to hint that the song of the nightingale has been overestimated in comparison with that of other native and foreign birds, some have gone to the extreme of regarding it as inferior to that of many thrushes; its natural song is certainly very sweet, but not more so, in the opinion of Audubon, than that of the black-capped warbler, and but little, if at all, superior to that of the wood lark; the song of the sky lark is far more spirited, more prolonged, and of much greater compass, though less sweet; the notes of the American mocking bird are very much sweeter, more varied, of greater compass, power, and duration; and many birds, which naturally have no song, like the bullfinch, can be taught to sing in perfect time and tune, which the nightingale cannot. But, take it as a whole, it must be confessed to be superior at least to that of all British songsters; Izaak Walton exclaims in regard to it: "Lord, what music hast thou provided for the saints in heaven, when thou affordest bad men such music on earth?" The compass of its song is only 11 or 12 notes. (See Macgillivray's "British Birds," vol. ii. p. 381, London, 1839.) The males only sing, and, like other migratory birds, never during the winter in cages, and not till after the spring moult. They are short-lived in captivity from being kept too warm and from improper food; this should be chiefly insects, or small bits of meat and fruits.

NIGHTINGALE, FLORENCE, an English philanthropist, born in Florence, Italy, in 1823. She is the younger daughter and co-heiress of William Edward Shore, of Embley, Hants, and Lea Hurst, Derbyshire, and descendant of an old and respectable Sheffield family, who inherited the estates of his paternal grand-uncle Peter Nightingale, and in pursuance of his will assumed in 1815 the name of Nightingale by royal sign manual. Her mother is a daughter of the late William Smith, who was for many years a member of parliament for Norwich, and distinguished as an advocate of negro emancipation. As the child of cultivated no less than of wealthy parents, the youth of Florence Nightingale, as well as that of her elder sister Parthenope, was passed under circumstances favorable to her intellectual development. Under the guidance of her father she attained proficiency in classics and mathematics, and a general acquaintance with science and art. She also became a good musician and proficient in modern languages, a branch of study which was facilitated by her early visits to many parts of Europe. From early childhood the care of the sick was a favorite occupation with her, and no reading possessed such attractions for her as that which treated of hospitals and other institutions for the infirm, helpless, and diseased. In her girlhood she often visited the schools and hospitals in the neighborhood of Lea Hurst, her father's residence, and subsequently the hospitals of the larger towns, devoting much attention to the best of London. She was at this time specially impressed with the necessity of an institution for training nurses. The sisters of charity of the Catholic church seemed to her to need a counterpart in the Protestant communion. At length she learned that such an institution existed at Kaiserswerth on the Rhine, in the "school of deaconesses" founded by Amelia Sieveking and the venerable Pastor Fliedner. To this school Miss Nightingale went in 1849, to qualify herself still further for the work of ministering to the sick. She entered as a voluntary nurse, placing herself under the care of Fliedner, and going through the regular course of training. After spending a little more than 6 months here, she returned to England, and for some months was in feeble health. In 1851, learning that the sanatorium for invalid and infirm governesses in Upper Harley street, London, was in need of competent management, she took charge of it, and in 15 months brought it into a far higher state of efficiency than it had ever previously possessed. This accomplished, she returned home again. In 1854 the need of good nurses and efficient hospital service in the Crimea was painfully felt, and the exposure of some of the abuses connected with it in the "Times" newspaper roused the attention of the whole British nation. A corps of voluntary female nurses was proposed, and at the solicitation of Mr. Sidney Herbert, the secretary at war, Miss Nightingale consent-

ed to go out as the superintendent of a staff of nurses; 42 went with her, and 50 more followed subsequently. Many of these were ladies of high social position, moved to devote themselves to this work solely by patriotism and philanthropy. On Nov. 5 Miss Nightingale and her corps arrived at Constantinople, and took up their quarters in the barrack hospital of Scutari. Two days later 600 wounded soldiers were sent to them from the battle of Inkermann; by the 30th of the month there were 8,000 sick and wounded at Scutari, and within 6 weeks 10,000 in the different hospitals on the Bosphorus. The disorder and want of suitable arrangements, of beds, food, and medicine, when Miss Nightingale commenced her labors, would have appalled almost any one else; but, possessing rare executive ability as well as thorough knowledge of what was necessary, she made the hospital in a short time a model in the thoroughness and perfection of its appointments. The other hospitals were made to conform to the same plan under her direction. All this involved an immensity of labor on her part; often she stood for 20 hours in succession giving directions, but she had always a pleasant smile or a kind word for the sick, and was soon almost idolized by the army. She remained nearly two years in the East, suffering herself one severe attack of hospital fever, but returning to her work as soon as she was able to sit up. She arrived in England Sept. 8, 1856. Her health, never robust, was permanently impaired, and since her return to England she has been much of the time an invalid. Her services have secured the sincerest gratitude of the British people, and a world-wide renown. The queen sent her a letter of thanks accompanied by a superb jewel; a subscription of £50,000 was raised to found an institution for the training of nurses under her direction; and the soldiers of the army, by a penny contribution, raised a sum sufficient to erect a statue to her honor, which she refused to allow. Miss Nightingale published in 1850 a pamphlet for the benefit of the sanatorium in Upper Harley street, entitled "The Institution at Kaiserswerth on the Rhine for the Practical Training of Deaconesses, under the direction of the Rev. Pastor Fliedner;" and in 1859 "Notes on Nursing," enlarged in a 2d edition (1860).

NIGHTMARE, or INCUBUS, an affection coming on during sleep, in which there is a sense of great pressure upon the chest accompanied by inability to move. It is well known that uneasy or painful sensations occurring during sleep, when insufficient to wake the patient directly, are apt to produce disagreeable or frightful dreams. Thus persons laboring under a variety of chronic affections, particularly heart disease, upon falling asleep suffer from dreadful illusions; they are attacked by wild beasts or armed men, they are falling down precipices, &c. The same phenomenon often occurs during fever or after mental excitement

attended with anxiety. The more common form of nightmare usually comes on during the first sleep, and is caused by a constrained position or by a distended stomach, which act by somewhat impeding respiration. The feeling of oppression thus caused gives rise to the nightmare, and is dispelled at once when the patient awakes, and, bringing the voluntary muscles into play, draws a full breath.

NIGHTSHADE (*solanum nigrum*, Linn.), an annual plant introduced from Europe, and occurring about waste places all over the world. Its stem is herbaceous, smooth, erect, angular; its leaves are sinuate, toothed, and downy; flowers white in small and umbel-like, lateral clusters, drooping, succeeded by numerous black berries filled with a purple pulp, in which the seeds are imbedded. It is slightly narcotic, although it possesses the reputation of a poisonous plant. The common nightshade belongs to the natural order of *solanaceae*, which embraces many of the most dangerous plants known, as well as many useful and esculent ones.—The deadly nightshade (*atropa belladonna*, Linn.) has ovate entire leaves, dirty violet-brown flowers, and pitted seeds enclosed in a berry destitute of pulp. Its uses in materia medica are well known. The enchanter's nightshade (*circœa lutetiana*) belongs to another order, and is an innocuous plant.

NIGRITIA. See **SOODAN.**

NIJNI NOVGOROD, or **LOWER NOVGOROD**, a government of central Russia, bounded N. by Kostroma, N. E. by Viatka, E. by Kasan and Simbirsk, S. by Penza and Tambov, and W. by Vladimir; area, 18,500 sq. m.; pop. in 1856, 1,216,091, about $\frac{1}{4}$ of whom are Tartars, and the remainder chiefly Russians. The province is traversed by the Volga, and by its affluents the Vetluga, Sura, and Oka, and has direct communication by water both with Moscow and St. Petersburg. Steamers proceed by the Volga to Astrakhan, and by the Kama to Perm. The surface is generally level, with a few low hills, nowhere more than 500 feet high, and composed chiefly of limestone. The N. E. portion, enclosed by the Volga and Vetluga, has been until lately almost unknown. It is covered with forests mostly of fir and birch, and has a sandy and in some places marshy soil. The climate is 10° colder than that of the surrounding country. The habitations are almost wholly confined to a few scattered hamlets. The rest of the government is extremely fertile, and, having a mild climate, produces abundance of grain, hemp, flax, and fruit. The forests yield excellent timber. The mineral productions are iron and gypsum. There are few large manufactories, but most of the villages and towns produce on a small scale a great variety of articles, including spun and woven goods, pottery, cloth, soap, candles, iron, and steel.—**NIJNI NOVGOROD**, the capital of the above government, is situated on the right bank of the Volga, where it is joined by the Oka, 255 m. E. from Moscow, in lat. 56° 20' N.,

long. 44° 1' E.; pop. about 80,000. The principal part of the town is built on a steep triangular promontory, about 400 feet high, between the Volga and Oka, and consists mainly of 8 handsome streets which radiate from an open space in the centre. At the point of the promontory stands the Kremlin or citadel, defended by a wall 30 feet high flanked with towers. The chief public buildings, including 2 cathedrals, a Protestant church, and the governor's palace, are situated within the Kremlin. There are more than 40 churches, one of the finest of which is the church of the holy women. The houses are mostly of wood, but the shops and warehouses are generally of more substantial materials. Cloth, leather, copper and iron ware, soap, candles, and beer, are the principal manufactures; and the trade, which is at all seasons very extensive, is increased by the annual fair in July and August, at which as many as 200,000 persons are present. (See **FAIR**.) A particular quarter is set apart for this great gathering, and at all other times remains unoccupied.

NIKOLAIEV, or **NICOLAIEFF**, a town of Russia, in the government of Cherson, near the confluence of the rivers Bug and Ingul, 86 m. N. W. from Cherson; pop. about 40,000. It occupies a large extent of ground, and is fortified. The streets are of enormous width; the houses are generally of one story, and have large gardens attached to them; and there is a fine boulevard planted with trees along the Bug. The principal public edifices are the cathedral, town hall, observatory, admiralty, naval barracks, naval hospital, and hydrographical seminary. The dockyards are very extensive, and well provided with machinery, mostly English. Nikolaiev, since the fall of Sebastopol, has become one of the principal stations of the Russian navy. It is of recent origin, having been founded in 1791, and is mainly indebted for its prosperity to government patronage. The Bug and Ingul, which unite below the town, form an estuary for the accommodation of the Black sea fleet during winter.

NILE (Gr. *Νεῖλος*; Lat. *Nilus*; Arab. *En-Neel*), the principal river of Africa, and one of the largest and most famous rivers of the world. Near the city of Khartoom, in the Egyptian province of Soodan or Sennaar, in lat. 15° 40' N., long. 32° 38' E., two great rivers unite, the larger of which comes from the S. W., and is called in Arabic Bahr-el-Abiad or White river, and in English is commonly known as the White Nile. The other river flows from the S. E., and is called in Arabic Bahr-el-Azrek, Blue, or more properly Black river, and in English is commonly termed the Blue Nile. It is the Astapus of ancient geography, and was long regarded as the true Nile, and as such its sources were visited in the 16th century by the Portuguese Jesuit missionary Paez and some of his associates. On Nov. 14, 1770, Bruce, the Scottish traveller in Abyssinia, after a toilsome

and dangerous journey, also succeeded in reaching its remotest fountains, which flow from a small hillock in the midst of a marsh in the district of Geesh, in lat. $10^{\circ} 59' 35''$ N. and long. $86^{\circ} 55' 30''$ E., at a height of nearly 6,000 feet above the sea. Here are 8 small, deep springs, which are regarded by the neighboring people with superstitious veneration. Their waters form a stream which flows N. W. for about 80 m., when it falls into the lake of Dembea on its W. side, and issues again on its S. E. side. Its current is so rapid that it scarcely mingles its waters with those of the lake. It now takes the name of the Abai, and, descending from the highlands by many cataracts, flows southward to about lat. 10° N. along the E. side of the province of Amhara, and winds around the mountainous region of Gojam till by a bend to the N. it returns to within about 70 m. of its source. While forming this remarkable curve, which makes Gojam a peninsula, the Abai receives numerous streams from the mountains of that peninsula. Still lower down, in lat. $11^{\circ} 30'$, a large river called the Hessen, coming from the S. E., joins the Abai on its right bank. Soon afterward the waters of the Abai mingle with those of a large river called the Dedhesa, and from their junction till they reach the White Nile at Khartoom the united streams are known as the Bahr-el-Azrek or Blue Nile. The Dedhesa is considered by Dr. Beke to be the main stream of the Blue Nile, of which he regards the Abai as only a branch. The Dedhesa rises in the mountains of Enarea, and has a course of several hundred miles W. of S. before it joins the Abai. An expedition led by Russegger, a German traveller, in 1837-'8 ascended its left bank as far as lat. $10^{\circ} 16'$, or considerably above its junction with the Abai. The Blue Nile he ascertained to be navigable as far as Fazogle, under the 12th parallel, about 1,500 m. from the Mediterranean. Its total length from the sources of the Abai is supposed to be about 800 m.—The sources of the Bahr-el-Abiad, or White Nile, so called from the color given to its waters by the clay with which it is saturated, are yet undiscovered, and great uncertainty exists as to the upper part of the river S. of lat. $3^{\circ} 20'$ N., to which point it has been explored by expeditions sent up from Khartoom by the pasha of Egypt. Capt. Speke, an English officer, who, in company with Capt. Burton, travelled in 1858 from the E. coast of Africa to the great lake Tanganyika, the N. extremity of which is in lat. $3^{\circ} 25'$ S., made a separate excursion to Nyanza, another great lake lying 250 m. to the N. E. of Tanganyika, and extending N. from lat. $2^{\circ} 30'$ S. to an unknown distance beyond the equator. A small river flows into the S. end of this lake, and on its W. shore it receives several streams from a mountain range which Capt. Speke calls the mountains of the Moon. On the E. side it is supposed to receive a large river which rises in the snowy mountains S. of the equator, of which Mt. Kenia is the principal peak. Capt. Speke

considers Lake Nyanza as the true source of the Nile, and the river Kivira flowing from its N. extremity as identical with the Bahr-el-Abiad. Capt. Burton, who did not accompany him on his excursion to Lake Nyanza, dissents from this opinion, though his objections, as stated in "The Lake Regions of Central Africa," are chiefly theoretical, and are manifestly influenced by personal hostility to Capt. Speke. He admits that "the altitude, the conformation of the Nyanza lake, the argillaceous color, and the sweetness of its waters combine to suggest that it may be one of the feeders of the White Nile;" but says on the other hand: "The periodical swelling of the Nyanza lake, which, flooding a considerable tract of land on the south, may be supposed—as it lies flush with the basal surface of the country—to inundate extensively all the low lands that form its periphery, forbids belief in the possibility of its being the head stream of the Nile, or the reservoir of its periodical inundation. In Karagwah, upon the western shore, the *masika* or monsoon lasts from October to May or June, after which the dry season sets in. The Egyptian expedition found the river falling fast at the end of January, and they learned from the people that it would again rise about the end of March, at which season the sun is vertical over the equator. And as the northern counterslope of Kenia will, to a certain extent, be a lee land like Ugogo, it cannot have the superfluity of moisture necessary to send forth a first class stream. The inundation is synchronous with the great falls of the northern equatorial regions, which extend from July to September, and is dependent solely upon the tropical rains. It is therefore probable that the true sources of the 'holy river' will be found to be a network of runnels and rivulets of scanty dimensions, filled by monsoon torrents, and perhaps a little swollen by melted snow on the northern water-parting of the eastern Lunar mountains." Capt. Burton also discredits the theory that Lake Tanganyika is one of the sources of the Nile, and maintains that the lake has really no outlet. As he was unable to reach its northern extremity, his opinion, which is based chiefly upon questionable native statements, is far from conclusive. The great extent of the lake and the vast quantity of water poured into it by its affluents, together with its freshness, render it highly improbable that it can be without an effluent. A native African, Lief ben Saied, who travelled from Zanzibar to the lake, and furnished an account of his expedition which was communicated by the eminent African geographer Mr. Macqueen to the "Journal of the Royal Geographical Society," says: "It is well known by all the people there that the river which goes through Egypt takes its source and origin from the lake." Capt. Speke also reports, in "Blackwood's Magazine" for Sept. 1859, a statement made by Sheik Hamed, a respectable Arab merchant, who asserted from personal observation that a large river flowed

out of the N. end of the lake. The truth of this assertion is, however, denied by Capt. Speke; and Capt. Burton, from inquiries made by him of the people at the furthest northern point reached by the English travellers, unceremoniously pronounces the statement a deliberate falsehood. But Dr. Beke, the highest authority on these questions, says in his recent work on "The Sources of the Nile" (London, 1860), speaking of Lake Tanganyika: "Its elevation of merely 1,800 feet seems to militate against its connection with the Nile, especially as it is said to be encircled and shut in at its N. extremity by a range of mountains. Still, it is not absolutely certain that Tanganyika has no outlet through or round those mountains; and beside, as the elevation of the Nile at Khartoom is only 1,300 feet, while from about lat. 12° N. the main stream and its principal arms are almost on a dead level, we should be wrong in asserting the physical impossibility of a connection between the lake and the river." In the 2d century A. D. the geographer Claudius Ptolemy stated the sources of the Nile to be in two lakes lying N. of a snowy range which he calls the mountains of the Moon, and which he describes as extending for 10° of longitude along the parallel of lat. $12^{\circ} 30'$ S. From the snows of these mountains were principally derived the waters of the two lakes, which were due N. of the mountains, the western lake in lat. 6° and the eastern lake in 7° S., with a distance between them of 8° of longitude. Recent explorations show the substantial accuracy of Ptolemy's information; though, from the inevitable imperfection of astronomical science in his day, his latitudes and longitudes are incorrectly given, and the snowy range of mountains of which he speaks extends from N. to S. instead of from E. to W. The recent Egyptian explorers ascertained that the White Nile above lat. 10° N. divides into several large streams, of which the Sobat and the Tubiri are the principal. The Sobat unites with the Tubiri near lat. 9° N. It is a very large river, and is said to contribute to the main stream nearly half its waters. Little is known however of its upper course, which has never been explored, the Egyptian expeditions having ascended the Tubiri. The latter river, or one of its branches, in the opinion of Dr. Beke, probably flows from Lake Nyanza, which he regards as the eastern lake of Ptolemy. There are reports of a great lake said to be situated in the W. of the Fandongo country, which lake M. Brun-Rollet, a French explorer, lays down conjecturally on the equator, and relatively as much to the N. W. of Tanganyika as Nyanza is to the N. E. This may possibly be the western lake of Ptolemy, and the source of one of the branches of the White Nile. Lopez, a Portuguese traveller near the end of the 16th century, as cited by Pigafetta in his *Relations del reame di Congo* (1591), reported the existence of two great lakes in the interior of Africa, and says: "The Nile truly has its origin in this first lake,

which is in lat. 12° S., and it runs 400 m. due N., and enters another very large lake, which is called by the natives a sea, because it is 220 m. in extent, and it lies under the equator." Dr. Beke is of opinion that the second lake here mentioned is probably not Nyanza, but the yet unvisited lake mentioned by M. Brun-Rollet, if that lake really exists. He says in conclusion: "It is, however, of little avail to reason on insufficient data. This alone is certain—that all the head streams of the Nile must be thoroughly explored before it would be in our power to finally and irrevocably decide which among them is entitled to the designation of the source of the Nile." A French expedition under MM. Miani and Peglioux is now (1860) exploring the White Nile. The latest intelligence from the upper part of the river is from Mr. Petherick of Khartoom, who after ascending from that city 400 m. proceeded by land for 25 days in a southerly direction, and reached, in long. 27° E., and nearly under the equator, a granitic ridge of mountains rising from 2,000 to 2,500 feet above the plain. Beyond that point nothing is yet known.—The course of the White Nile above its junction with the Blue Nile at Khartoom was first explored in 1837 by M. Linant, who ascended the stream as far as El-Ais in lat. $18^{\circ} 48'$ N. A few years afterward Mehemet Ali, pasha of Egypt, determined to have the river explored to its sources. Accordingly, between 1839 and 1842, three expeditions were fitted out for that purpose; the first ascended to lat. $6^{\circ} 30'$ N., discovering on its passage the mouth of the Sobat, Lake No, and the Bahr-el-Ghazal; the second reached lat. $4^{\circ} 42'$ N.; and the third went not quite so far. M. d'Arnaud, the scientific chief of the second and most successful expedition, states in his published report that at about 90 m. beyond the furthest point reached by him several branches united, of which the principal one came from beyond an extensive country called Bari. Lacono, the king of Bari, told the explorers that the course of the river could be followed southward a distance of 30 days' journey or 600 or 700 m. beyond his dominions. Of this expedition an account was also published by Ferdinand Werne, a German who went with D'Arnaud as a volunteer. His work, *Expedition sur Entdeckung des weissen Nile*, has been translated into English under the title of "The White Nile" (3 vols., London, 1849).—In Nov. 1849, Dr. Knoblecher, a Roman Catholic missionary at Khartoom, accompanied the annual trading expedition sent up the Nile by the Egyptian authorities. After 14 days' sailing the expedition passed the islands inhabited by the Shillooks, a numerous and savage negro nation, and reached a part of the river where the banks were covered with continuous villages to the estimated number of 7,000. The river was here so broad that in some places the low shores were hardly visible. The lotus grows abundantly in the shallows, and the appearance

of the thousands of snowy blossoms as they flash open at sunrise is described as a scene of vegetable pomp and splendor which can be witnessed in no other part of the world. Beyond lat. 10° is the land of the Dinkas, where the beautiful dhelleb palm is first seen, which has a tall, graceful trunk, thick in the middle, but tapering toward the top and bottom, and a rich crown of large, fan-like leaves. The forests also comprise doum palms and immense tamarinds. On Nov. 29 the vessels reached a large town called Vav, where the people brought quantities of elephants' tusks to exchange for beads. Herds of wild elephants and giraffes were now frequently seen, with numbers of white herons perched composedly on the backs and heads of the elephants. On Dec. 2 the expedition passed the mouth of the Sobat, which is 650 feet broad at its entrance into the Nile. From lat. $9^{\circ} 26'$ to $6^{\circ} 50' N.$ there is a complete change in the scenery. The forests disappear, and the shores become marshy and covered with tall grass. The air is heavy with noxious miasmas and filled with countless swarms of gnats and mosquitoes. The water of the river is partially stagnant and green with vegetable matter. In lat. $9^{\circ} 16'$ is the Bahr-el-Ghazal, or Gazelle lake, thus named from the Gazelle river, which flows into it on the W. side. The depth of the lake is about 9 feet, but the reeds and water plants with which it is filled reach to the surface and render the navigation difficult. Its shores are inhabited by Nuehr negroes. Beyond this lake the course of the river is exceedingly tortuous and its current sluggish. Beyond lat. 8° was the land of the Kyks, a race of herdsmen who have great numbers of cattle and sheep. Their principal chief resides at the village of Augwen. South of the Kyks dwell the Elliabs, in whose country the river divides into two branches. On Dec. 31 the expedition reached the country of the Zhirs; and on Jan. 2, 1860, Dr. Knoblecher saw in the S. E. the granite mountain of Nierkanyi, which is in the Bari country in lat. $5^{\circ} N.$ It was the first elevation he had seen since passing lat. $10^{\circ} 35'$. The intervening space is a vast plain interspersed with reedy swamps of stagnant water. The Zhirs are very superior to the Nuehrs and Kyks in stature, shape, and manners, own numerous flocks and herds, and cultivate large fields of grain. They go entirely naked, but are remarkably chaste and modest. On Jan. 14 the expedition reached the rapids of the White Nile at the island of Tsanker, in lat. $4^{\circ} 49' N.$, the furthest point reached by any previous expedition. Dr. Knoblecher, however, succeeded in passing the rapids and in sailing 16 m. further through a broad, lake-like expanse of the river, to the Bari village of Tokiman. The country was exceedingly rich and beautiful, abounding in trees and densely peopled; the current of the river was rapid, and the atmosphere pure and healthful. On Jan. 16 the expedition reached Logwek, a village which takes its name from a

granite peak 600 feet high on the left bank of the Nile, in lat. $4^{\circ} 10'$. Dr. Knoblecher ascended this hill, which commanded a view of almost the entire Bari country, and saw the river winding out of sight among a range of mountains toward the S. W. Its width at Logwek was about 650 feet and its depth from 5 to 8 feet, the season being a dry one. The Baris are a fine race of negroes, many of them 7 feet high, with well knit, symmetrical, muscular, and active forms. They are fearless and independent in their demeanor, and cheerful, good-natured, and affectionate. In smelting and working iron they show remarkable skill, and their spears are elegantly formed and admirably tempered. Beyond Logwek Dr. Knoblecher was unable to penetrate; and although several European explorers have since ascended the White Nile, nothing definite is at the present time (Dec. 1860) known of the result of their researches. Bayard Taylor, in his "Journey to Central Africa," thus concludes his account of Dr. Knoblecher's expedition: "The pictures which these recent explorations present to us add to the stately and sublime associations with which the Nile is invested; and that miraculous flood will lose nothing of his interest when the mystery which veils his origin shall be finally dispelled. Although, in standing upon the threshold of his vast central realms, I felt that I had realized a portion of my dream, I could not turn away from the vision of those untrodden solitudes, crowned by the flashing snows of Kilimandjaro, the monarch of African mountains, without a keen pang of regret. Since Columbus first looked upon San Salvador, the earth has but one emotion of triumph left in her bestowal, and that she reserves for him who shall first drink from the fountains of the White Nile, under the snow fields of Kilimandjaro."—From Khar-toom the united waters of the White Nile and Blue Nile flow northward about 50 m., and then make a sudden bend to the E. between a thick cluster of islands. At this point there is a rapid extending half way across the river, and dignified by the title of the 12th cataract of the Nile, it being the last which is met in ascending from the sea till the traveller reaches on the White Nile the rapids in the Bari country, and on the Blue Nile the cataracts by which the river descends from the Abyssinian highlands. Here the Nile is very narrow, being compressed between high hills of naked red sandstone rock. From the 12th cataract it flows in a S. E. direction to Shendy, and is studded with islands covered with a luxuriant growth of palms, mimosas, acacias, sycamores, and other trees. The banks are high and steep and covered with bushes and rank grass. Reefs of black rock make the navigation intricate and dangerous. The country is thickly populated with Shygeean negroes. Shendy is a long straggling town of mud huts, with about 10,000 inhabitants. From Shendy the river runs N. E. past the ruins of Meroë and through

a country cultivated with durra and cotton of excellent quality. At the distance of 160 m. below Khartoom, in lat. $17^{\circ} 45'$, the Atbara, called also Bahr-el-Aswad or Black river from the quantity of black earth brought down by it during the rains, enters the Nile on the right bank, flowing from the S. E. It is the ancient Astaboras, and comes from Abyssinia, where it is known as the Tacazze. The peninsula between it and the Blue Nile was the ancient kingdom of Meroë, which was called an island by the Greek and Roman writers, who were accustomed to give this name to the irregular spaces included between confluent rivers. The Atbara is the last confluent of the Nile, which for the rest of its course presents the unparalleled phenomenon of a river flowing 1,500 m. without a branch. It contributes to the Nile the largest part of the slimy mud which fertilizes Egypt. At about 50 or 60 m. up its stream the Atbara receives from the E. the Mogreb, which rises in the Bishariyeh mountains near the Red sea; and 100 m. higher up still, on the E. side, it approaches the Khor-el-Gash, a stream which flows into the Red sea, while its waters during and after the rainy season also overflow into the Atbara, though during the dry season this communication altogether ceases. In lat. 14° N. the Atbara divides into two great streams, the larger of which bears the name of Tacazze, and rises in the table-land of Abyssinia in the provinces of Angot and Lasta; and the other, the Gwangwe or Goang, which is the direct continuation of the Atbara, has its sources in the highlands to the N. and N. W. of Lake Tsana or Dembea. From its confluence with the Atbara the Nile flows through Nubia for 700 m. to Syene or Asswan on the frontiers of Egypt. It passes over a series of rapids and cataracts, all composed of granite or kindred rocks. For 120 m. from the Atbara it runs nearly N. through the country of the Berbers. A strip of arable land about 2 m. in breadth borders the river; beyond it all is desert, the inundation not extending further. At Abou Hammed, where the river is divided by the large rocky island of Mogreb, it makes a great bend to the S. W., and runs in that direction about 100 m., enclosing on its left bank a region called the desert of Bahiouda, which was occupied in ancient times by the Nubæ, from whom Nubia derives its name. The navigation in this part is impeded by rapids, and the land susceptible of cultivation is so small in extent that the inhabitants avail themselves of the patches of loamy soil which the river deposits in the rocky hollows. Travellers going down the Nile quit the river at Abou Hammed and cross the desert to Korosko, a march of 250 m., while by the course of the river the distance between the same points is upward of 600 m. The banks of the Nile where it skirts the desert of Bahiouda on the N. contain no antiquities; but at Nouri on the left bank, below the 4th cataract, are the remains of 85 pyramids, of which about half

are in good preservation; they have, however, no sculptures or hieroglyphics, nor are there any ruins which indicate the former existence of a city. Eight miles below Nouri, on the right bank, is Jebel-el-Birkel, a hill of crumbling sandstone 400 feet in height, and a mile distant from the river. On the W. side of the hill are 13 pyramids from 35 to 60 feet in height. Here are also the remains of several large Egyptian temples, one of them nearly 500 feet in length. These ruins are supposed to mark the southern limits of the empire of the Pharaohs, and the city to which they belonged was probably Napata, the capital of Tirhaka, the king of the Ethiopians, and also of those sovereigns of Ethiopia who are mentioned in the ancient history of Egypt. A short distance below Jebel-el-Birkel, on the right bank of the river, is the village of Merawe, nearly opposite to which is the point from which travellers up the Nile begin their march across the desert of Bahiouda to Shendy, and thus cut off the great upper bend of the river. After passing Merawe the Nile continues to the S. W. till it reaches lat. 18° , when it turns again to the N. In this part of its course it is about half a mile wide. The desert on both sides reaches to the banks, and there is little cultivable land except on the islands. The kingdom of Dongola, now subject to the pasha of Egypt, begins at this point, and reaches to the second cataract nearly 300 m. northward. This region is tolerably fertile, the banks of the river being no longer rocky, and the annual inundation diffusing itself over a large extent of land, abounding in fine pastures and producing a breed of excellent horses. A little above the third cataract, in lat. $19^{\circ} 12' N.$, is the island of Argo, which is 12 m. long, and contains a number of ruins, among them two overthrown colossal statues of gray granite in Ethiopian costume with Egyptian features. Below the third cataract, in lat. 20° , the Nile makes a large bend to the E.; and travellers usually take a straight line through the desert to Saleb on the left bank, where are found the ruins of a temple remarkable for the elegance of its architecture and its imposing and picturesque position on the line which separates the desert from the fertile land. A few miles below, the large island of Sais divides the river, which soon after contracts between granite rocks so closely that it is but a few hundred feet in width. The rocks hang over the shore and fill the river with shoals, causing so many eddies, rapids, and shallows, that navigation is practicable only at the time of highest flood, and is even then dangerous. About half way between the island of Sais and the second cataract, in lat. $21^{\circ} 29'$, is the village of Semneh on the left bank, where are the remains of a large temple of great antiquity; and on the opposite side is another of still larger dimensions and of equal antiquity. These buildings mark the site of a populous city, whose name has been lost from history. As the river approaches the second

cataract in lat. 22°, the porphyritic and granitic rocks on its banks give place to sandstone. The second cataract, which was called by the ancients the great cataract, is, like all the others, formed by primitive rocks rising through the sandstone, in a succession of islands dividing the stream, which foams and rushes between them, with a roar which may be heard at the distance of more than a mile. It is rather a collection of rapids than a fall. A city once existed here, and the remains of three ancient temples are yet visible. From the second cataract to the frontier of Egypt, a distance of 220 m., there is a multitude of temples, some on the right, some on the left bank, the most remarkable of which are those of Abou Sambool or Ipsambul, anciently Ibesciak, on the left bank, two days' journey below the cataract. (See Abou Sambool.) A few miles lower down, at Ibrim, the ancient Primis, are ruins of the same kind, of the age of Thothmes I. and Rhameses III. Just beyond Ibrim the channel of the river is compressed between a range of sandstone hills rising almost perpendicularly, so close to the shore that there is hardly room to pass between their bases and the water. A few miles below, at Derr, the capital of Lower Nubia, the river bends abruptly to the S. and then again to the N. All this region abounds in temples of Rhameses III., Thothmes III. and IV., and Amenoph II. Amada, two hours' sail below Derr, has a temple whose sculptures are of a high order of merit; and the traveller descending the river passes in rapid succession Wady Esseboua, the valley of Lions; Dakkeh, the site of a temple of Thoth; Pselcis, the furthest point to the S. at which any traces of Greek or Roman dominion have been found on monuments; Dandour, the site of a temple of the age of Augustus; and Kalabsche, the ancient Talmis, situated in lat. 28° 30', directly under the tropic of Cancer, where there is a temple founded by Amenoph III., rebuilt by one of the Ptolemies, and repaired by Augustus, Caligula, and Trajan. The Nile in this part of its course is described by Mr. Bayard Taylor as "a river of the north under a southern sun. The mountains rise on either hand from the water's edge; piles of dark sandstone or porphyry rock, sometimes 1,000 feet in height, where a blade of grass never grew, every notch and jag on their crests, every fissure on their sides, revealed in an atmosphere so pure and crystalline that nothing but one of our cloudless mid-winter days can equal it. Their hue near at hand is a glaring brown; in the distance an intense violet. On the W. bank they are lower; and the sand of that vast desert, which stretches unbroken to the Atlantic, has heaped itself over their shoulders and poured long drifts and rills even to the water. In color it is a tawny gold, almost approaching a salmon tint, and its glow at sunrise almost equals that of the snow fields of the Alps. The arable land is a mere hem, a few yards in breadth on either side of the river. It supports

a few scattering date palms, which are the principal dependence of the Nubians. . . . This part of Nubia is inhabited by the Kenoo tribe, who speak a language of their own. They and their language are designated by the general name of Barabra, nearly equivalent to barbarians, by the Arabs. They are more stupid than the Egyptian fellahs, but their character for truth and honesty is superior." The rise of the Nile during the annual inundation is in some parts of this region as much as 80 feet, but the height of the banks is such that the adjacent land derives little benefit from the overflow. At the boundary between Nubia and Egypt is the island of Philæ, where the Nile is 8,000 feet broad. It is about a quarter of a mile long, and is covered with picturesque ruins of temples, almost entirely of the times of the Ptolemies and of the Roman emperors. Immediately below Philæ are the falls called the first cataract, the last in descending the river, which extend to Asswan, the ancient Syene, and to the island of Elephantiné. The ridge of granite by which they are caused crosses the river and extends into the desert on either side. The rocks are much more rugged than those of the second cataract, and rise to the height of 40 feet. There are three principal falls; at the steepest, which is about 80 feet wide, the descent is about 12 feet in 100. The entire descent in a space of 5 m. is 80 feet, and the whole constitutes a series of rapids rather than falls, and may be passed by boats when the water is high. From the quarries on the banks were derived the colossal statues, obelisks, and monoliths which are found throughout Egypt. The island of Elephantiné, just opposite to Syene, is fertile and covered with verdure. From Syene to the Mediterranean, a distance of 700 m., the Nile runs down a gentle declivity of about 600 feet. The valley through which it flows till it reaches the apex of the delta varies in breadth, and has an average of 7 m., the greatest width being 11 m. A short distance below Syene begins a district of sandstone, which extends nearly to lat. 25°. This part of the valley is narrow and barren. Near lat. 25° is Edfoo, the ancient Apollinopolis Magna, which stands on the right bank, and has two famous temples built by the Ptolemies, the largest of which is the best preserved of all the edifices of the kind in Egypt. At Esneh or Latopolis, on the W. bank, 80 m. westward, the valley of the river expands to the width of nearly 5 m. Here are the remains of a magnificent temple built by the Roman emperors. Still lower down the rocks of Jebelain or the "two mountains" approach so near each other on opposite sides, that the river occupies nearly the whole valley. Here the sandstone disappears, and limestone hills succeed, which border the river till it reaches the delta. There is consequently from this point a wider interval of fertile land, especially on the W. side. Fifty miles below Edfoo stand the magnificent ruins of Thebes, the ancient capital of Upper Egypt.

Here the river is $1\frac{1}{2}$ m. wide, and is divided by islands. On the right bank are the modern villages of Luxor and Karnak, on the left Medinet Abou and Gourna. From Thebes the traveller descending the river passes numerous ruins, at Medamot, at Kooe or Apollinopolis Parva, and at Ooptos on the right bank; and on the left bank, 88 m. below Thebes, reaches Dendera, the ancient Tentyra, where are seen the majestic remains of the temple of Athor, one of the most impressive of Egyptian monuments. Not far below this the river bends to the W., and at How or Diospolis Parva on the left bank begins the canal or ancient branch of the Nile, called the Bahr Jusuf or river of Joseph, which flows between the river and the Lybian hills to the entrance of the Fayoom. Not far distant is Abydos or This, one of the most ancient cities of Egypt, the birthplace of Menes, the first of the Pharaohs. Beyond this are Chemnis or Panopolis on the E. bank, Syoot, the ancient Lycopolis, on the W. bank, and a little lower down on both banks the grottos of Manfalout, the sepulchres of embalmed dogs, cats, and crocodiles. Still lower are the ruins of Hermopolis Magna on the W. side, and the remains of Antinoë built by Hadrian in the Roman style. North of Antinoë, on the E. bank, are the famous grottos of Beni-Hassan, about 30 in number, excavated by the kings of the 18th dynasty, and containing paintings of scenes in the civil and domestic life of the ancient Egyptians, from which modern Egyptologists have derived most of our knowledge of the manners and customs of that people. From this point the course of the river presents no remarkable feature till it reaches Beni-Sooef in lat. 29° , where the Libyan chain of hills begins to retire from the river, bends toward the N. W., and again returning toward the river encloses the province of Fayoom, in which were the lake of Mœris, the labyrinth, and the city of Crocodilopolis. The next objects of interest in descending the stream are the pyramids of Dashoor and of Saccara, and finally the great pyramids of Gizeh, the royal sepulchres of ancient Memphis. This metropolis, whose remains have been lately discovered by M. Marietta, stood on the W. bank. A few miles lower down, on the E. bank, is Cairo, the present capital. A little above Cairo the double chain of hills between which the Nile has so long flowed terminates, those on the E. side turning off toward the head of the Red sea, and those on the opposite side returning toward the N. W. From this point the Nile expands, and its current slackens, and soon begins to flow sluggishly in separate branches. Twelve miles below Cairo is the apex of the delta, the point of separation, which in ancient times was 6 or 7 m. higher up. From here to the sea the delta spreads for 90 m., a broad and perfectly level alluvial plain, without a hill, rock, or natural elevation of any kind. Anciently the Nile traversed the delta by 7 branches, of which only 8 appear to have been of much size, the Pelusiatic or eastern

arm, the Canopic or western, and the Sebennytic or middle arm. The Pelusiatic branch is now dry. On the E. side of it, not far from the apex of the delta, was Heliopolis, the On of Scripture, of whose ruins only an obelisk remains. Twenty miles lower down was Bubastis; and still lower, near the sea, though its remains are now several miles inland, was Pelusium, from which the mouth derived its name. The ancient Sebennytic branch had its mouth where the lake of Bourlos now lies, but the greater part of its course is represented by the more easterly of the two present mouths of the Nile, that of Damietta. The Canopic branch is represented by the first part of the present Rosetta branch as far as lat. 31° , whence it turned to the W. and entered the sea near the bay of Aboukir. The two mouths by which the river now enters the Mediterranean are about 80 m. apart, and are in lat. $30^{\circ} 31' N$. The W. or Rosetta branch is the usual channel of communication between Alexandria and Cairo, and is navigated by small steamers at regular intervals; it is 1,800 feet broad, and has in the dry season a depth of about 5 feet. The Damietta branch is 900 feet wide, and its depth when the river is lowest is about 8 feet.—In the ordinary state of its waters the Nile has not depth sufficient for vessels of more than 60 tons burden, but during the height of the inundation the depth of water is 40 feet, and large vessels can ascend to Cairo. The river begins to rise in Egypt in the latter part of June, and reaches its greatest height between Sept. 20 and 30, when it is usually at Cairo 24 feet above the low water level, and at Thebes 36 feet. About the middle of October it begins to fall, and is at the lowest about the middle of May. The rise sometimes reaches 80 feet, and the overflow then does great damage; on the other hand, when it falls short of 18 feet, the harvests fail, and Egypt experiences a famine. Of the 66 inundations between 1735 and 1801, 11 were very high, 30 good, 16 feeble, and 9 insufficient. The water of the river is charged with mud, which it deposits during the inundation over the cultivated land of Egypt to an average depth of not more than the 20th part of an inch each year. Notwithstanding its turbidness, the water is sweet and wholesome, and is freely drunk by the people, among whom the saying is proverbial that he who has drunk of the Nile will always long to return and drink of it again.—On the island of Rhodah, near Cairo, is the celebrated nilometer for indicating the height of the Nile during the annual inundation. It consists of a square well or chamber, in the centre of which is a graduated pillar, divided into cubits of about 22 inches each. A nilometer existed at Memphis in the times of the Pharaohs, and during the reigns of the Ptolemies there was one at Eilethya, and another at Elephantine in the reigns of the early Roman emperors. The first nilometer built after the Arab conquest was erected at Helwan about A. D. 700. The present one in

the island of Rhoddah is attributed to the caliph Amin, who reigned from 813 to 833. During the inundation 4 criers proclaim every morning in the streets of Cairo the height to which the water has risen. When it has reached 18 cubits the canals are opened and it is allowed to flow over the land.—Just below the apex of the delta is the *barrage* or great dam, commenced by the French engineer Linant and still unfinished. It is intended to hold back the waters and keep them in reserve, so that by letting them out at proper seasons two inundations may be produced in a year. It will consist when completed of 62 arches spanning each of the two channels into which the Nile is here divided (the Damietta and Rosetta branches), beside a central arch 90 feet in width, flanked by lofty stone towers. The point of the delta between the two branches is protected by a curtain of solid masonry, and the abutments which join it are fortified by towers 60 or 70 feet high. The piers have curved breakwaters on the upper side. The material is brick faced with stone. During low water it is intended to close the side arches, and thus gain water enough to fill all the irrigating canals. A French company for the establishment of a line of steam tow-boats on the Nile was approved by the viceroy, Oct. 9, 1854.—The Nile abounds with fish, among which are large eels, white trout, and a large species of salmon. The overflow of the White Nile brings down vast quantities of fish, probably from some great lake. Crocodiles and hippopotami abound in the upper part of the river, but the hippopotamus is seldom found below the 2d cataract, and the crocodile has been exterminated from Lower Egypt.

NILES, a town of Berrien co., Mich., on the right bank of the St. Joseph river, near the mouth of the Dowagiac, and on the Michigan central railroad, 192 m. W. by S. from Detroit; pop. in 1859 estimated at 5,000. It is pleasantly situated in the centre of a rich agricultural region, and is the seat of a branch of the state university. It contains also a number of mills and manufacturing establishments, 2 weekly newspaper offices, and 6 churches, viz.: Baptist, Congregational, Episcopal, Methodist, Presbyterian, and Roman Catholic.

NILES, HEZEKIAH, an American journalist, born Oct. 10, 1777, died in Wilmington, Del., April 2, 1839. He is chiefly known as the founder in 1811 of "*Niles's Register*," a weekly journal, published at Baltimore, of which he was the editor till Aug. 1836. The "*Register*" was republished by him in 32 volumes, extending from 1812 to 1827, and was continued by his son W. O. Niles and others till June 27, 1849, making 51 volumes in all.

NILES, JOHN MILTON, an American author and statesman, born in Windsor, Conn., Aug. 20, 1787, died in Hartford, Conn., May 31, 1856. Receiving only a common school education, until his 20th year he was principally engaged in labor upon the farm, cultivated by himself

and an elder brother. At that age he applied himself to study, and afterward entered a law office. While yet a student he warmly espoused the policy of President Madison, in opposition to the general sentiment which then prevailed in Connecticut. Not being immediately successful in his profession, he visited in 1815 Vermont, New York, and Pennsylvania, with some idea of finding a new home, but returned to Connecticut undecided. In 1817, with the coöperation of others, he established the "*Hartford Times*," of which he was principal editor for several years, and to which he contributed for 30 years. He was appointed in 1821 by the general assembly one of the associate judges for the county court of Hartford, and in 1826 was elected representative from the town of Hartford to the general assembly. He was nominated for senator in 1827, but was unsuccessful on account of his known partiality for Gen. Jackson. He was appointed postmaster of Hartford in 1829, but resigned on receiving the executive appointment of U. S. senator, a post made vacant by the death of Nathan Smith, which he retained until 1839. In 1839 and 1840 he was the democratic candidate for governor of Connecticut, and in the latter year he became postmaster-general under President Van Buren. He was again elected to the U. S. senate in 1842; and on the expiration of his term in 1849 he retired from official life. He edited for republication in 1816 a large English work, "*The Independent Whig*," and compiled in conjunction with Dr. John C. Pease, his brother-in-law, a gazetteer of Connecticut and Rhode Island, published in 1819. He was also the author of a "*Life of Commodore Oliver H. Perry*" (Hartford, 1820); "*History of South America and Mexico, and a View of Texas*" (Hartford, 1839); and a number of pamphlets containing orations, addresses, &c., upon a great variety of subjects. By his will he bequeathed \$70,000 in trust to the city of Hartford, as a charity fund, the annual income of which was to be distributed among the poor.

NILES, NATHANIEL, an American clergyman, inventor, and politician, born in South Kingston, R. I., April 8, 1741, died Oct. 31, 1828. He was graduated at Princeton college in 1766, afterward studied medicine and law, and taught for a time in New York city. Under Dr. Bellamy he studied theology and was licensed to preach, but refused to settle over any church, although he preached in several places in New England. Becoming a resident of Norwich, Conn., he invented a process of making wire from bar iron by water power, and connected it with a wool card manufactory. After the revolution he removed to Orange co., Vt., and filled subsequently several public offices in that state, was speaker of the house of representatives in 1784, judge of the supreme court for several years, a representative in congress from 1791 to 1795, one of the censors for the revision of the state constitution, and 6 times presidential elector. He continued to preach, how-

ever, as long as his health permitted. He published four "Discourses on Secret Prayer" (1773); two "Discourses on Confession of Sin and Forgiveness;" two sermons on "The Perfection of God, the Fountain of Good" (1774); a sermon on vain amusements; and a "Letter to a Friend concerning the doctrine that impenitent sinners have the natural power to make to themselves new hearts" (1809). He also wrote a "History of the Indian War," published in the "Massachusetts Historical Collections," and the "American Hero," a Sapphic ode, once very popular in Norwich, and still occasionally sung.

NIMEGUEN, *NYMWEGEN*, or *NIJMEGEN* (anc. *Noviomagus*), a strongly fortified frontier town of Holland, in the province of Gelderland, on the left bank of the Waal, about 10 m. from Arnhem and Cleves; pop. about 21,000. It is built on several hills, on which in ancient times the Romans had formed a camp to guard their Batavian possessions against the Germans. It is a well built town, though the streets are narrow. The most remarkable public building is the town hall, containing a few Roman antiquities, the swords of Egmont and Horn, statues of German emperors, and portraits of the ambassadors connected with the treaty of peace signed there in 1678, between Spain, France, and Holland, followed in 1679 by that between the two former countries and Germany and Sweden. On the principal hill (*Hönderberg*) are the ruins of the castle of Falkenhof, said to have been built by Charlemagne; and not far from it is the fine café and promenade of the Belvedere, a lofty structure, originally built under the direction of the duke of Alva.—Nimeguen was formerly a Hanse town. After joining in 1579 the Utrecht league of the United Provinces of the Netherlands, it was taken by the Spaniards in 1582, and recovered by Maurice of Orange in 1585. In 1672 it was taken by Turenne; but in 1702 it resisted another attack of the French.

NÎMES, or *Nismes* (anc. *Nemausus*), a city in the S. E. of France, capital of the department of Gard, 80½ m. by railway N. E. from Montpellier and 79 m. N. W. from Marseilles; pop. in 1856, 54,298. The city proper is small and irregularly laid out, with narrow streets and ill-built houses; but its 8 suburbs, one of which, called the *Cours-Neuf*, is larger than the city itself, present a finer aspect, having wide, straight avenues, fine public walks, and handsome buildings. The remains of antiquity which Nîmes contains are surpassed by those of no other European city except Rome. The *maison carrée*, so called from its rectangular form, is a beautiful Corinthian temple nearly in the centre of the city, and presents a fine specimen of Roman architecture. It stands on a stylobate, and is approached by 15 steps; the platform is 82½ feet long and 40½ feet wide, and the building and platform together are 58½ feet high. It is surrounded by 80 columns, 10 of which are detached and form the portico. It suffered great-

ly during the middle ages, and it is only since 1789 that it has been taken care of, restored, and surrounded by an iron railing. In 1823 it was converted into a museum of paintings and antiquities, called the *musée Marie Thérèse*. The amphitheatre, or *les arènes*, is the most perfect, if not the largest structure of its kind extant. Its height outside is from 68 to 104 feet, and its external circumference 1,174½ feet. It has from 32 to 35 ranges of seats, and was capable of accommodating from 17,000 to 23,000 spectators. It was used as a fortress by the Visigoths and the Saracens, when attacked by the Franks; during the following centuries it was also occupied as a stronghold. No fewer than 2,000 persons had established their abode within the walls of this building, when in 1809 it was cleared by order of the prefect; and it has since been protected against encroachments. The *tour magne* (*turris magna*) is the remnant of a tower which flanked the ancient walls. The boulevards now occupy the site of the ramparts, but portions of them are still extant in the *porte d'Auguste* and *porte de France*, two Roman gates, the former of which is ornamented with sculptures. To these monuments must be added a ruined *nymphæum*, a fane dedicated to the nymphs, which communicated with a neighboring bath for women, the remains of which have been mistaken for those of a temple of Diana. The magnificent aqueduct, known as the *pont du Gard*, is in the vicinity of Nîmes. (See *GARD*, *PONT DU*.) Among the edifices of a later period are the cathedral, begun in the 11th century, but constructed chiefly in the 16th and 17th, occupying the site of a temple of Apollo; the church of St. Paul; the new palace of justice; the general hospital; the *hôtel Dieu*, rebuilt in 1830; the public library; the central house of detention, which is the citadel built by Vauban over the remains of the old Fort Rohan erected in 1629 by the Calvinists; and the fine monumental fountain by Pradier, erected in 1851, on the esplanade. The public garden, where is still to be seen the fountain that furnished the Roman baths with water, and the beautiful promenade known as the *cours Feuchères*, must not be forgotten.—Nîmes is the seat of a bishop, and has an imperial court, tribunals of primary jurisdiction and commerce, a departmental academy, several learned institutions, a lyceum or college, a normal school, a theological seminary, schools of drawing, chemistry and physics, geometry and mechanics as applied to the arts, a society of medicine, a Bible society, and a cabinet of natural history. In point of industry and commerce it holds a distinguished rank; it is the great southern mart for raw and manufactured silk. Its manufactures are principally silk shawls and hosiery; mixed silk, cotton, and woollen stuffs; blonde lace and tulles, galloons, ribbons, and carpets. There are several large-dyeing and printing establishments, vinegar factories, and distilleries. Its trade is mostly in wine, brandies, vinegar, essences, castor and.

almond oils, oleaginous and leguminous seeds, and medicinal and tinctorial plants. A *conseil de prud'hommes* and a chamber of commerce watch over the interests of workmen and manufacturers.—Nimes was occupied by the Romans in 121 B. C. It was already one of the most important cities of Gaul and the capital of the Voies Arecomici. Augustus, Tiberius, Trajan, Hadrian, Antoninus, and Diocletian contributed to its embellishment. But, pillaged by the Vandals, occupied by the Visigoths from 465 to 507, and then by the Franks, taken by the Saracens, from whom it was wrested by Charles Martel in 737, visited by the Norman pirates, ill treated by its feudal lords, it dwindled away, until in the 14th century its population scarcely amounted to 400. It revived, however, and Francis I. assisted in its restoration. Most of its new inhabitants being Calvinists, it suffered during the religious war of the 16th century, and was severely treated by Louis XIII. and Louis XIV. It was also involved in bloody conflicts in 1791 and 1815.

NIMROD, a personage mentioned in Gen. x. 8, 9, 10, in the following manner: "And Cush begat Nimrod: he began to be a mighty one in the earth. He was a mighty hunter before the Lord; wherefore it is said, Even as Nimrod the mighty hunter before the Lord. And the beginning of his kingdom was Babel, and Erech and Accad and Calneh in the land of Shinar." He is mentioned in the Bible only twice afterward—in 1 Chron. i. 10: "And Cush begat Nimrod: he began to be mighty upon the earth;" and in Micah v. 6: "And they shall waste the land of Assyria with the sword, and the land of Nimrod in the entrances thereof." Cush, the father of Nimrod, was the son of Ham and the grandson of Noah. The name Nimrod in Hebrew implies rebellion and apostasy, and may be translated "the impious rebel." The commentators upon the Bible are generally of opinion that Nimrod was a man of great bodily strength and courage, who first became distinguished as a slayer of wild beasts, and afterward as a military chieftain who was the first conqueror and despot, and the founder of government by force instead of by consent, as in the patriarchal rule which he overthrew and supplanted. Some have endeavored to identify him with the Babylonian Belus, others with the Assyrian Ninus. Sir Henry Rawlinson, the latest investigator of Babylonian antiquities, is of opinion that by Nimrod is probably meant the first dynasty that reigned in the region watered by the Tigris and Euphrates. It appears from the monuments that the cities which in Genesis are said to have formed the kingdom of Nimrod were founded by two early kings named Uruk and Ilgi. According to Berosus, this dynasty began in 2284 and ended in 1976 B. C.; and the dates obtained from the inscriptions are in agreement with this calculation. In Arabic history and tradition the seat of Nimrod's empire is placed at Cutha, about 12 miles from Babylon. The

Arab tribes of Mesopotamia have many traditions about him, and have given his name to many places, as for instance to the Birs Nimroud, or Nimrod's tower, at Babylon, and to the great mound Nimroud on the site of Nineveh.

NIMROUD, BIRS. See BELUS, TEMPLE OF.

NINEVEH (Gr. *Ninos*; Lat. *Ninus*; Assyrian, *Ninua*), an ancient city of Asia, the capital of the Assyrian empire, situated on the E. bank of the Tigris, opposite the present city of Mosul, and about 220 m. N. N. W. from Bagdad. The earliest mention of Nineveh that has come down to us is in the Bible, Gen. x. 11, 12, where it is said that out of the land of Shinar "went forth Asshur and builded Nineveh and the city Rehoboth and Calah, and Resen between Nineveh and Calah." It is next mentioned about 720 B. C. by the prophet Nahum, who denounces "woe to the bloody city! it is all full of lies and robbery," and predicts its speedy overthrow; at the same time alluding to its great riches, its strongholds, its merchants "multiplied above the stars of heaven," and its mighty princes and captains. Isaiah (xxxvii. 37) speaks of Sennacherib king of Assyria as dwelling at Nineveh about 710 B. C.; and Zephaniah (ii. 13) prophesies that the Lord "will make Nineveh a desolation and dry like a wilderness." But the only mention of it in the Scriptures which contains any details is in the book of Jonah. That prophet was commanded to "go to Nineveh, that great city, and cry against it. . . . Now Nineveh was an exceeding great city of three days' journey, . . . wherein are more than six score thousand persons that cannot discern between their right hand and their left hand." Much difference of opinion exists among commentators as to the exact meaning of the phrase, a "city of three days' journey," a day's journey being commonly reckoned at 20 miles, and three days' at 60 miles. By some it has been supposed to refer to the circumference; but as it is expressly stated that Jonah "began to enter into the city a day's journey," it seems evident that the expression was intended to apply to the diameter, for otherwise the prophet in a day's journey, instead of merely beginning to enter the city, would have traversed its entire length or breadth. The extent of a day's journey, as the phrase is here used, may have been much less than 20 miles, or the expression may be merely figurative and intended to indicate loosely the great size of the city. The statement that Nineveh contained 120,000 persons unable to "discern between their right hand and their left hand" has been construed to mean that there were that number of infants or children under 5 years of age, which, according to the usual calculation, would have made the entire population 600,000. But this is only a conjecture, as the real meaning of the passage, as of that which refers to the size of the city, is still a matter of speculation. All that can be certainly inferred from the biblical narrative is that Nine-

veh was very large and populous. The earliest mention of the city by any extant classical writer is in Herodotus, i. 193, who speaks of the Tigris as "the river upon which the city of Nineveh formerly stood," the place having been destroyed about 200 years before. Strabo mentions it as a city larger even than Babylon. Diodorus, copying Otesias, places it on the Euphrates; though in an extract from Otesias preserved in a fragment of Nicolaus Damascus, it is properly stated to be on the Tigris. The error has probably crept into the text of the historian by the carelessness of some transcriber. Diodorus, following Otesias, describes the city as forming a quadrangle of 150 stadia by 90, the circumference being thus 480 stadia or about 60 miles. The city was overthrown and its empire merged in that of Babylon, according to Sir Henry Rawlinson, in 625 B. C.; and so completely had it disappeared that Xenophon, though in 401 B. C. he led the 10,000 Greeks over the ground on which it had stood, does not even mention its name; and though 70 years later Alexander fought the great battle of Arbela in the vicinity, none of his historians allude to the ruins of the city. Huge mounds, apparently of mere earth and rubbish, covered its site, the largest of which are known to the inhabitants of Mosul and its vicinity at the present day as the mounds of Nimroud or Nimrod, of Kouyunjik, of Selamiyah, and of Nebbi Yunus or the tomb of Jonah, so called from the current belief among the people that the sepulchre of the prophet is on its summit, a tradition which probably originated in the former existence on the spot of a Christian church dedicated to Jonah. Kouyunjik is directly opposite Mosul, and about a mile from the Tigris. It measures 866 yards by 500. Nebbi Yunus is about a mile S. E. of Kouyunjik, and measures 566 by 400 yards. These two mounds are enclosed by the remains of a wall, the entire length of which was nearly 8 m., and which surrounded an irregular quadrangular space 3 m. in length with an average breadth of about a mile. Nimroud is about 20 m. S. of Kouyunjik, near the junction of the great Zab with the Tigris. Selamiyah is 3 m. to the N. of Nimroud. About 15 m. N. E. of Nimroud is the mound called Karamles; and 12 m. N. E. of Mosul is the mound of Khorsabad, consisting of two parts, an upper, about 650 feet square and 30 feet high, and a lower part connected with it, about 1,350 feet by 800.—The first accurate description and plan of these ruins was given by Claudius James Rich, who was for several years the English East India company's political agent at Bagdad. He made in 1820 a survey, which was published after his death. From the neighboring inhabitants he learned that not long before his visit sculptured figures of men and animals had been dug out of one of the mounds, and had been destroyed as idols. He collected, however, a few specimens of pottery and bricks inscribed with cuneiform

characters. In 1843 M. Paul Émile Botta, French consul at Mosul, after having examined the mound of Kouyunjik without making discoveries of much importance, turned his attention to the mound of Khorsabad, where he soon laid bare the ruins of a magnificent palace which had evidently been destroyed by fire. He found among the remains a series of apartments panelled with slabs of coarse gray alabaster, on which were sculptured in bass-relief figures of men and animals, with inscriptions in the cuneiform or arrow-headed character. In Nov. 1845, Austen Henry Layard, an English traveller, began excavations at Nimroud, which were continued till April, 1847, with great success. He discovered immense quantities of sculptures, inscriptions, pottery, and antiquities of all sorts, by means of which more light has been thrown on the history and civilization of the Assyrians than by all the accounts transmitted to us by the writers of antiquity. Excavations with like results were also made in the mounds of Kouyunjik and Nebbi Yunus. In the latter part of 1849, under the direction and at the expense of the trustees of the British museum, Mr. Layard resumed his explorations, and continued them for about a year.—From the researches of Messrs. Botta, Layard, and other investigators, it appears that the great mounds, or rather groups of mounds, Kouyunjik, Nimroud, Selamiyah, and Khorsabad, were fortified places, surrounded by walls enclosing an area large enough, in each case, for a considerable city. Recent surveys have shown that Kouyunjik, Khorsabad, Nimroud, and Karamles occupy the 4 corners of a square, the area of which is very nearly of the extent assigned to Nineveh by the Greek writers. Sir Henry Rawlinson is of opinion that these places were all distinct cities, and that the mound of Nebbi Yunus marks the site of Nineveh, which he thinks was only about 9 m. in circumference. He admits, however, that in the time of Jonah the common name of Nineveh was applied to the whole group of cities. Mr. Layard, on the contrary, considers Kouyunjik the site of the most ancient city, which gradually expanded until it enclosed within its walls an area 60 m. in circumference, including several great fortified palaces which continued to bear distinct local appellations, in the same manner as Westminster, Southwark, and other parts of London are still known by their individual names. This great space, however, was not wholly covered with houses, but comprised, as is the case in many oriental cities at the present day, extensive gardens and arable and pasture land. Jonah speaks of much cattle within the walls; and as Babylon, according to Diodorus and Quintus Curtius, contained vacant land enough to supply corn for the population during a siege, it is probable that Nineveh was built in a similar manner. That part of the city of which the mounds of Kouyunjik and Nebbi Yunus are the remains seems to have been, at

least at one period, the most important and the most strongly fortified. A deep moat defended the N. side; the western walls were washed by the Tigris, which now flows in a different channel nearly a mile distant; a moat and wall defended the S. side; and on the E. side, which was the most exposed, the strongest artificial defences were raised, consisting of a moat 200 feet broad and a wall 100 feet high. It is probably to this portion of the fortifications that the descriptions of the Greek writers properly refer, though with natural exaggeration they applied the same colossal scale to the entire fortifications of the metropolis.—The most ancient edifice discovered by Mr. Layard is that termed by him the north-west palace, at the N. W. corner of the mound of Nimroud. It was founded or rebuilt on the site of a still older palace by Asshur-dan-pal, who is supposed to have been the warlike Sardanapalus of the Greeks, and who must be distinguished from the effeminate king of the same name. He appears to have reigned about 950 B. C. This palace was nearly square, about 360 feet in length and 300 in breadth. A second palace in the centre of the same mound was built by his son Shalmanubar, and rebuilt by a succeeding monarch, Ivalush III., who also built a third palace in the immediate vicinity. Ivalush III. is the Pul of the Scriptures, and his queen is supposed to have been named Semiramis, though not the famous heroine of the Greek writers. The palace discovered at Khorsabad by M. Botta was built about 725 B. C. by a king who is called Sargon in Isa. xx. At Kouyunjik Mr. Layard disinterred a great palace founded about 700 B. C. by Sennacherib, on whose monuments have been discovered inscriptions containing the name of Hezekiah and a record of the invasion of Judæa and siege of Lachish, when in the 14th year of King Hezekiah "Sennacherib king of Assyria came up against all the fenced cities of Judah and took them." (2 Kings xviii. 13.) These palaces were all built upon enormous platforms raised about 40 feet above the level of the plain, either by heaping up earth and rubbish or by masonry of sun-dried bricks. The platforms were faced with stone, and were ascended by broad flights of steps. The palaces themselves were constructed principally of sun-dried bricks, though kiln-burnt bricks were used for the solidier parts, and a coarse alabaster quarried near the city was used for ornament. The walls of these buildings were generally about 15 feet thick, and were lined with sculptured alabaster slabs from 8 to 10 feet high, from 3 to 4 broad, and about 18 inches thick. The apartments were high, and the spaces above the slabs were plastered and painted or were faced with bricks, coated with enamel of elegant designs and brilliant colors. Ivory, bronze, and cedar from Mt. Lebanon were also used for decoration, which was heightened by gilding and painting. The principle of the arch was understood by

the Assyrians, and the arched doorways to the principal apartments were guarded by colossal figures of lions or bulls with human heads and the wings of an eagle. On these figures were historical inscriptions recording the exploits of the king by whom they were erected. In some of the palaces that have been discovered the panelling of sculptured slabs is nearly a mile in length. The principal and favorite subjects of these representations are war abroad and state at home. There are separate sculptured histories of each campaign of the king, and delineations of the taking of all the considerable cities that resisted him. These sieges and the treatment of the captives, which was barbarous in the extreme, as they were sometimes flayed alive, and representations of the king or his officers receiving tribute or homage from the conquered people, form the most common scenes of the bass-reliefs. Many of the sculptures, however, are of a purely religious nature; some are wholly occupied by scenes of the chase; some are actually landscape paintings; and many represent thrones, chariots, or domestic furniture and utensils. No Assyrian women ever appear in the sculptures, though women are sometimes represented as captives or as begging for mercy from the walls of a falling city. As only the lower part of the walls of the palaces of Nineveh have been found, it is uncertain what was the nature and arrangement of the upper part. The absence of windows makes it difficult to comprehend how the apartments could have been lighted. Mr. Layard at first supposed them to have consisted of only a single story with apertures in the ceiling to admit light; but he now is understood to incline to a plausible theory advanced with great ability and ingenuity by Mr. Fergusson, who maintains that there was an upper story supported by columns and open at the sides to admit light to the rooms below, from which the sunshine could be excluded at pleasure by means of curtains. This open upper story was used in fine weather, and as a balcony from which the king could show himself to his subjects or review his troops. The columns which supported its roof stood some of them on the floor of the lower story, and other shorter ones on the walls of the lower story, whose immense thickness is thus accounted for. These edifices, though not equalling those of the Greeks in elegance and artistic taste, nor those of the Egyptians in solid magnificence and strength, must have been exceedingly gorgeous and beautiful structures. They were in part temples as well as palaces, the king being not only political chief but high priest of the nation, as was the case at one period in Egypt. "The interior of the Assyrian palace," says Mr. Layard, "must have been as magnificent as imposing. I have led the reader through its ruins, and he may judge of the impression its halls were calculated to make upon the stranger who, in the days of old, entered for the first time the abode of the Assyrian kings. He was

ushered in through the portal guarded by the colossal lions or bulls of white alabaster. In the first hall he found himself surrounded by the sculptured records of the empire. Battles, sieges, triumphs, the exploits of the chase, the ceremonies of religion, were portrayed on the walls, sculptured in alabaster and painted in gorgeous colors. Under each picture were engraved, in characters filled up with bright copper, inscriptions describing the scenes represented. Above the sculptures were painted other events—the king, attended by his eunuchs and warriors, receiving his prisoners, entering into alliances with other monarchs, or performing some sacred duty. These representations were enclosed in colored borders of elaborate and elegant design. The emblematic tree, winged bulls, and monstrous animals were conspicuous among the ornaments. At the upper end of the hall was the colossal figure of the king in adoration before the supreme deity, or receiving from his eunuch the holy cup. He was attended by warriors bearing his arms, and by the priests or presiding divinities. His robes and those of his followers were adorned with groups of figures, animals, and flowers, all painted with brilliant colors. The stranger trod upon alabaster slabs, each bearing an inscription, recording the titles, genealogy, and achievements of the great king. Several doorways, formed by gigantic winged lions or bulls, or by the figures of guardian deities, led into other apartments, which again opened into more distant halls. In each were new sculptures. On the walls of some were processions of colossal figures—armed men and eunuchs following the king, warriors laden with spoil, leading prisoners or bearing presents and offerings to the gods. On the walls of others were portrayed the winged priests, or presiding divinities standing before the sacred trees. These edifices were great national monuments, upon the walls of which were represented in sculpture or inscribed in alphabetic characters the chronicles of the empire. He who entered them might thus read the history and learn the glory and triumphs of the nation. They served at the same time to bring continually to the remembrance of those who assembled within them on festive occasions, or for the celebration of religious ceremonies, the deeds of their ancestors and the power and majesty of their gods." The palaces of Nineveh appear generally to have been destroyed by fire, which however could not injure the incombustible and massive walls of the lower part of the first story. These with their sculptures were probably at once buried by the falling in of the upper stories and of the higher part of their own structure, and the ruins were in time wholly concealed by the accumulation of rubbish from the villages subsequently built on them and by the mould of decaying vegetation, through the course of 3,000 years.—Though the most ancient edifice yet discovered, the north-west palace at Nimroud, dates only from

the 10th century B. C., there can be no doubt that Nineveh was founded several centuries before, and probably as early as 22 centuries B. C. Its name is mentioned in Genesis and is found on Egyptian monuments 14 centuries B. C. For a long period Nineveh seems to have been under the dominion of Babylon. Sir Henry Rawlinson is of opinion that about 1278 B. C. Assyria became independent and the seat of a great empire, whose capital however was at Asshur, now Kileh-Shergat, on the right bank of the Tigris, 60 m. S. of Nineveh. Ninus and Semiramis he regards as mythical personages, not belonging at all to Assyrian tradition, but inventions of the Greek writers. The Babylonian historians, according to Abydenus, ignored altogether the existence of any such monarchs. The earliest known king of Assyria was Bellush, who was succeeded by Pudil, Iva-lush, and Shalmabar, whose reigns were probably between 1273 and 1200 B. C. A dynasty of 6 kings succeeded, reigning till 1050 B. C., the crown descending from father to son. Their names are recorded on a cylinder found at Kileh-Shergat, and, as Rawlinson proposes to read them, are Nin-pala-kura, Asshur-dapal-il, Mutaggil-nebu, Asshur-rish-ili, Tiglath-Pileser I., and Asshur-bani-pal I. The true reading of the first of these names is very uncertain, but the inscription declares that he was the king who first organized Assyria. Asshur-rish-ili, the 4th of the dynasty, is called "the powerful king, the subduer of foreign countries, he who reduced all the lands of the Magian world;" from which it appears that he was a great conqueror, like his son Tiglath-Pileser I., who subdued Cappadocia, Syria, and parts of Media and Armenia. It is not certain who succeeded Asshur-bani-pal I., but the next king whose name is ascertained was Asshur-adan-akhi, who is supposed to have ascended the throne about 1050 B. C., and to have been a contemporary of David. He was succeeded by Asshur-danin-il, Iva-lush II., Tiglath-Nin, and Asshur-dani-pal or Sardanapalus, who according to Rawlinson transferred the seat of government from Kileh-Shergat to Nineveh. This monarch was a great conqueror, and carried his arms far and wide through western Asia, from Babylonia and Chaldea on the one side to Syria and the Mediterranean on the other. He was succeeded by his son Shalmanubar or Temenbar, who, after a warlike and victorious reign of more than 30 years, between 900 and 850 B. C., was succeeded by his son Shamasiva, who was followed by his son Iva-lush III., who is supposed to be the Pul of the Scriptures, and to have reigned from 800 to 747 B. C. With him his dynasty ended, and Tiglath-Pileser II. ascended the throne, probably by usurpation. His successors were Shalmaneser, Sargon, a usurper, and his son Sennacherib, who rebuilt and enlarged Nineveh, which had fallen into decay. He reigned upward of 22 years, and conquered Babylon

and Jerusalem. In a second expedition against the latter city and against Egypt, "the angel of the Lord went out and smote in the camp of the Assyrians an hundred fourscore and five thousand." His reign ended by his murder by two of his sons at Nineveh, one of whom, Asshur-akh-iddina or Esarhaddon, ascended the throne and reigned at least 13 years. His buildings exceed in magnificence those of any former Assyrian king, and his conquests extended not only over all western Asia, but into Egypt, and even into Ethiopia. In the latter part of his reign, however, Babylon seems to have rebelled and to have established its independence. Esarhaddon was succeeded by his son Asshur-bani-pal II., who about 640 B. C. transmitted the decaying empire to Asshur-emit-ili, the last king of whom any records have been as yet discovered. Either this monarch or a brother and successor Saracus was the last sovereign of Nineveh, and identical with the famous voluptuary Sardanapalus, of whom the Greek writers have given the imaginary history on which Lord Byron founded his tragedy. All that is really known of his history is that he was besieged in Nineveh by the revolted Medes and Babylonians, and in 625 B. C. an extraordinary flood of the Tigris swept away a portion of the city wall, upon which the king set fire to his palace and destroyed himself. The conquerors plundered and burned the rest of the city, which was never rebuilt. The total duration of the kingdom of Assyria seems to have been about 650 years; and for at least 5 centuries it was a great and powerful nation, dominant over western Asia, and comprising among its provinces or vassal states Susiana, Chaldea, Babylonia, Media, Armenia, Mesopotamia, Cappadocia, Cilicia, Syria, Phœnicia, Palestine, Idumæa, and for a time lower Egypt and the island of Cyprus.—The letters and literature of the Assyrians seem to have been derived originally from Babylon, and were apparently not much cultivated on a native basis, science and learning having been confined to a priest class which did not aim at progress. In art and manufactures the people had made great advances. In architecture, and to a less degree in sculpture and painting, they had attained a skill which, considering the period in which they lived, is truly admirable. Their art has every appearance of thorough and entire nationality, and shows in its development not only remarkable grandeur, dignity, and strength, but a growing grace and delicacy of execution which indicates that it was progressive and not stationary like that of the Egyptians. The vases, jars, bronzes, glass bottles, carved ivory and mother-of-pearl ornaments, engraved gems, bells, dishes, ear rings, arms, and working implements which have been found among the ruins of Nineveh, are almost invariably of elegant form, and indicate considerable knowledge of metallurgy and other arts, as well as a refined taste. They anticipated inventions which till lately were

believed to be comparatively modern, such as transparent glass, the magnifying lens, the principle of the arch, the construction of aqueducts and drains, and the arts of inlaying, enamelling, and overlaying with metals, and of cutting gems with the greatest skill and finish. "Their civilization," says Rawlinson, "equalled that of almost any ancient country, and did not fall immeasurably behind the boasted achievements of the moderns. With much that was barbaric still attaching to them, with a rude and inartificial government, savage passions, a debasing religion, and a general tendency to materialism, they were, toward the close of their empire, in all the arts and appliances of life, very nearly on a par with ourselves."

NINGPO, a city of China, in the province of Che-kiang, on the Takia or Ningpo river, near its mouth in the harbor of Chusan, 100 m. S. from Shanghai; lat. 29° 51' N., long. 121° 32' E.; pop. about 250,000. It is surrounded by a dilapidated wall about 6 m. in circumference, 25 feet high, and 15 feet broad at the top, with 5 gates. The streets are long and broad, and the town is intersected by canals and connected with its suburbs by a bridge of boats. There are several temples, the most remarkable of which is a brick tower 160 feet high, said to have been erected 1,100 years ago. There are government warehouses and public buildings. The houses are mostly one story high, but the shops are superior to those of Canton. In 1848 a missionary hospital was established at Ningpo, and all classes have resorted to it for surgical assistance. The ground in the neighborhood is flat and exceedingly fertile, but a range of barren hills runs along the sea shore. The principal manufactures are silk, cotton, and woollen goods; and there are very extensive salt works. Vessels of about 800 tons can come up to the town, while those of greater size load and unload at the mouth of the river. The foreign imports are small. Ningpo was taken by the British in 1841, and occupied for some months. It is one of the 5 ports opened to general intercourse by the treaty of Aug. 29, 1842.

NINON DE L'ENCOLOS. See L'ENCOLOS.

NIOBE, in Grecian mythology, a daughter of Tantalus, king of Lydia, by a nymph. She had 6 sons and 6 daughters, and boasting herself superior to Latona, who had borne only two children, Apollo and Diana, to avenge their mother, slew all the children of Niobe, who in her grief wept herself to stone.

NIOBIUM (symbol Nb), an obscure metal, commonly supposed by chemists to be identical with tantalum or columbium. H. Rose has recently made it the subject of very elaborate investigations, the results of which are published in Poggendorff's *Annalen*, civ. 810, 432, 581. By treatment of the double fluorides of niobium and the alkaline metals with sodium at a light heat in a cast iron crucible, he obtained the metal in the form of a black powder of specific gravity 6.297. It proves to be a conductor of

electricity, and is more easily acted on by reagents than tantalum. In nitric acid it is insoluble. Concentrated sulphuric acid dissolves it after long heating, and the solution has a brown color. It is also soluble in fluohydric acid, and by boiling with caustic potash or fusion with carbonate of potash. The metal ignites when heated in chlorine, and a yellow and white chloride are formed, the one, $NbCl_3$, being in much smaller quantity than the other, Nb_2Cl_5 . From these compounds Rose deduces the chemical equivalent of niobium 48.82 (or 610.87, oxygen being 100).

NIPHON, or NIPON, the principal of the Japanese islands, which gives its native name to the whole empire. It extends from lat. $41^{\circ} 45'$ to $33^{\circ} 26'$ N., and is separated on the N. from the island of Yesso by the strait of Sangar, on the S. from the islands of Kiusiu and Sikokf by narrow straits, and on the S. W. from Corea by a channel 120 m. wide. The island stretches from N. E. to S. W. in a curved form, and is about 900 m. in length with an average breadth of more than 100 m., it being 280 m. wide at the broadest part. The area is estimated at 100,000 sq. m., or $\frac{1}{16}$ more than that of the island of Great Britain. It is divided into 53 provinces, and contains the two imperial capitals Yeddo and Miaco, and many other large cities, of which the most noted is Osaka. The coasts are much and deeply indented, and are lined with detached rocks and small islands. The island is traversed from end to end by a range of mountains, of which the principal peak is the volcano Fusi-yama, 12,000 feet high. In these mountains are mines of gold, silver, and copper. Coal, naphtha, and porcelain clay are also found in the island. Among its vegetable productions are the palm, banana, sugar cane, rice, wheat, barley, the tea plant, beans, pepper, ginger, and camphor. The climate is subject to great extremes of heat and cold, especially in the north, but is generally healthy.

NISARD, JEAN MARIE NAPOLEON DESTRE, a French author, born in Châtillon-sur-Seine, March 20, 1806. At the age of 20 he became a regular contributor to the *Journal des débats*, but after the revolution of 1830 he broke off his connection with it on account of political differences, and wrote literary articles for the *National*, of which his friend Armand Carrel was then the editor. A steadfast admirer of the French writers of the 17th century, and particularly of Boileau, he was opposed to the new school of literature, and animadverted strongly upon its representatives in his first publication, *Les poètes Latins de la décadence* (8vo., 1834), in which he drew critical parallels between the minor Latin poets of the imperial period and the new French poets, as for instance between Lucan and Victor Hugo. His *Manifeste contre la littérature facile* was answered by Jules Janin, and the controversy became one of the chief literary events in Louis Philippe's reign. In 1835 Nisard was appointed by M. Guizot *maître de conférences* on French

literature in the normal school, afterward chief secretary to the minister of public instruction and master of requests in the council of state, and finally in 1837 chief of the department of science and literature. In 1842 he was elected to the chamber of deputies by his native department of Côte d'Or, and attached himself to the conservative party. In 1843 he became the successor of Burnouf as professor of Latin eloquence in the college of France, and this was the only office he retained after the revolution of Feb. 1848. In 1850, on the death of M. de Feletz, he was elected to the French academy. He had meanwhile been reconciled to the Bonapartists, and in 1852 was appointed general inspector of superior instruction; and on the retirement of M. Villemain with the title of honorary professor, Nisard succeeded him in the chair of French eloquence at the Sorbonne. Here M. Nisard was at first coldly received, and in 1855 he was hissed from his chair by the students; but with the assistance of the police he continued his lectures. In 1857 he was called to the directorship of the high normal school, which under his management is now (1861) undergoing a thorough renovation. Beside the works above alluded to, he has published *Histoire et description de la ville de Nîmes* (8vo., 1835); *Mélanges* (2 vols. 8vo., 1838); *Précis de l'histoire de la littérature Française depuis ses premiers monuments jusqu'à nos jours* (18mo., 1840), a valuable sketch, which was first printed in the *Dictionnaire de la conversation*; and *Histoire de la littérature Française*, a remodelling of his lectures at the normal school. Of this work, which is not yet completed, 8 volumes have appeared, including French literature to the end of the 17th century. His most important essays published in the reviews, have been reprinted under the titles of *Études sur les grands hommes de la renaissance* (12mo., 1856), and *Études de critique littéraire* (12mo., 1858), containing his essay *Les deux morales*, which has become celebrated for its intrinsic merits, as well as from the commotion which it produced at the Sorbonne. He has also superintended the publication of the *Collection des classiques Latins*, with a French translation (27 vols. 8vo., 1839 et seq.).

NISI PRIUS, a law term, which originated as follows. Anciently, nearly all actions in England of any importance were begun and tried before the courts of Westminster. But when the custom began of bringing actions of less value before these courts, and these grew to be numerous, the burden of coming from different and distant parts of England to London became very great; and a practice was introduced, some centuries since, of beginning a case in Westminster, as the law required, but continuing it from term to term, "unless before" the next term a court which could try the case should be held in the county where the cause of action arose or existed. The record was in Latin; and the words *nisi prius* (unless before), being the essential part, gave name to the

whole procedure. A court of eyre or of assize always did sit in the county in the vacation, and so the case was sure to be tried at home. Practically the phrase "nisi prius court," both in England and the United States, now signifies a court held by one of the judges, or less than a whole bench, usually with a jury, because such was the constitution of the assize courts before mentioned. Hence the determination of a law question at nisi prius is commonly made by one judge only, and on the spur of the moment. The nisi prius reports contain these rulings and decisions; as, for example, Espinasse's "Reports of Cases argued and ruled at Nisi Prius, in the Courts of King's Bench and Common Pleas," from 1798 to 1811; and Campbell's "Reports of Cases determined at Nisi Prius, in the Courts of King's Bench and Common Pleas," from 1807 to 1816. Such decisions have not, generally speaking, the weight and authority of the formal determinations of a court sitting *in banco*, or as a full bench, for the hearing of arguments at law. Many of the nisi prius reports, as for instance those above mentioned, are however of great value, and are constantly cited.

NISIBIS, in ancient geography, the capita. of Mygdonia, a district of Mesopotamia, on the river Mygdonius. It was important as a commercial city and a military post, being frequently conspicuous during the wars of the Romans against Armenia, Parthia, and Persia. From the latter part of the 4th century it remained in the hands of the Persians. Its ruins are now visible near Nisibin in the Turkish province of Diarbekir. Some critics, and among them Michaelis, identify the district in which it was situated with the Aram Zoba of Scripture; while others place the latter near Nisib on the Euphrates, a place known in modern history by the victory of Ibrahim Pasha over the Turkish army in 1839.

NITRATES, salts formed by the combination of nitric acid (see NITROGEN) with bases. Some of these are natural products, as the nitrates of potash, soda, lime, and magnesia; and others are artificially formed, as the nitrates of the oxides of the metals. Several of both kinds are sufficiently important to require particular mention. None of these salts possess acid reaction; they are distinguished for their solubility in water, and hence, the acid not forming a precipitate with any base, its presence, free or combined, can be determined only by other methods, several of which are described in works on chemistry. At a high heat the nitrates undergo decomposition, sometimes being converted into free nitric acid and the oxidized base, and sometimes into oxygen, which escapes, and nitrous acid, which remains in combination with the base, forming a nitrite. This may itself be decomposed by increase of heat. It is this property which renders the nitrates powerful oxidizing agents, and adapts them as fluxes, especially when there is also an affinity between the base and the oxidized body.—First

in importance among these salts is the nitrate of potash, called also nitre and saltpetre, represented by the formula KO, NO_3 , and hence consisting of one equivalent each of potash = 47.2, and nitric acid = 54, in 101.2 parts. It is a white salt crystallized in long 6-sided prisms, soluble in 4 or 5 times its weight of cold and $\frac{1}{2}$ its weight of boiling water, not subject to deliquesce, and possessing a sharp, cooling taste. It fuses without losing weight at 662° . In large crystals it is apt to contain water mechanically held, which retains in solution some of the foreign salts derived from the mother liquor, as sulphate of soda and the chlorides of potassium and sodium. Smaller crystals are commonly purer; but common salt is almost always present to some extent, and is particularly injurious to saltpetre designed for the manufacture of gunpowder. Saltpetre is known by its deflagrating with bright scintillations when thrown on red-hot coals. Its mixture with carbonaceous matters is explosive when highly heated; and when this mixture is intimately made the product is gunpowder; sulphur, which is commonly introduced, not being essential for this property. (See GUNPOWDER.) Saltpetre is obtained both as a natural and artificial product. It is generated wherever nitrogenous animal and vegetable matters undergo decomposition in the presence of moist calcareous earth containing potash, the temperature being generally above 60°F . Ammonia is produced, which is decomposed, its nitrogen forming with oxygen nitric acid, which combines with the alkaline earths present. Wood ashes determines the production of nitrate of potash, and nitrate of lime, also produced, may be made to yield its nitric acid to potash added to the mixed products in the form of carbonate of potash. Nitre forms naturally upon the walls of cellars and of caves as an efflorescence. On the surface of some soils in warm countries it also appears in this form after the rainy season, and in sufficient quantity to render its collection profitable. In Hindostan it is thus produced so abundantly and cheaply, that our own market is supplied almost wholly from Calcutta; and the native sources of this salt in the limestone caves of Kentucky and other states, which during the last war with Great Britain furnished this necessary ingredient of gunpowder, are now comparatively valueless. To separate the nitre from the earth which contains it, this is lixiviated with water, which dissolves out the soluble salts; and in the large vats into which the liquid is conveyed the salts crystallize as the water is evaporated by solar or artificial heat. The first crystals that form are crude saltpetre; nitrates of lime and magnesia mostly remain in the mother liquor, and are either thrown away with it, or in some cases are decomposed by treatment with carbonate of potash, and their nitric acid is thus recovered in new quantities of nitre. Natural saltpetre beds are also worked in Hungary, Egypt, Spain, and in various warm countries.

In the island of Ceylon Dr. J. Davy examined numerous caves in calcareous and feldspathic rocks, upon the walls of which nitre was largely collected. During the dry season the incrustation which formed in the wet months was removed by means of picks together with more or less of the rocky material. The whole was then crushed and treated with water, wood ashes being also added. The lye was then drawn off and evaporated. Some of these caves contained large quantities of the excrement of bats that resorted to them; but others, which also produced saltpetre, were not frequented by these animals. In hot countries it does not appear that the immediate presence of decomposing animal matters is essential to the production of saltpetre; but ammonia thus derived and existing in the atmosphere is no doubt brought to the potash.—In temperate climates the salt is artificially produced in what are called in Europe saltpetre plantations. These are compost heaps of animal and vegetable matters intermixed with earth, and with potash, lime, and magnesia, presented in porous form, as in ashes, marl, chalk, old mortar, &c. The heaps are exposed to the air, but it is better to protect them from the rain. Gutters are excavated around them, and in these are kept liquids from the cattle stalls and other similar fluids rich in nitrogen, with which the materials are occasionally moistened. As practised in Sweden, the heaps are worked over once a week in summer and once a month in winter, and twigs are introduced to keep them open. The work is generally continued 8 years, until the product of saltpetre amounts to about 5 ounces in 1,000 cubic inches. For an annual product of 10 cwt. it is necessary to work over full 120 cubic fathoms of earth, of which $\frac{1}{3}$ becomes ripe each year, and is removed from time to time from the outermost layers to be lixiviated. The crude product obtained is afterward purified by repeated solutions and crystallizations. In France, about the year 1775, great attention was given to the subject of producing saltpetre. No fewer than 66 treatises were furnished to the government in response to an offer of a prize for the best one; and from these the commissioners prepared a full treatise of their own. During the revolution Berthollet the chemist was actively employed in directing the manufacture in different parts of France. In later times the process has been investigated by Gay-Lussac, Liebig, and especially by Kuhlmann; and the improved methods are described in detail in Knapp's "Chemical Technology" (vol. i.), in Thénard's *Traité de chimie*, in Dumas' *Chimie appliquée aux arts*, and in Gmelin's "Handbook of Chemistry."—Beside its use for making gunpowder, nitre is employed in the manufacture of nitric acid. It is also a useful oxidizing flux in metallurgical operations, and in medicine is much used for its cooling properties in inflammatory affections, and also as a promoter of perspiration and the secretions of the liver. In acute rheu-

matism it is sometimes administered in doses repeated at intervals to the extent of 2 oz. in 24 hours; though $\frac{1}{4}$ oz. in concentrated solution causes heat and pain in the stomach, which may be followed by convulsions and death. When taken in poisonous quantities there is no antidote known, and the only relief is by the use of the stomach pump, laudanum to allay the pain, and mucilaginous drinks and cordials. Nitre is also a powerful antiseptic; and is used in the preservation of meats, as for curing hams.—Another variety of nitre, called cubic nitre, is the salt, nitrate of soda, NaO, NO_3 , consisting of one equivalent of soda = 31 parts, and one of nitric acid = 54 parts in 85. It is found in beds among the hills in the province of Tarapaca which skirt the coast of Peru, and at their base on the W. side of the pampa over an extent of not less than 150 miles. As described by John H. Blake, Esq., in the "American Journal of Science" (vol. xlv., 1848), these low hills, rising but little above the level of the plain, are covered with a light, sandy marl mixed with minute fragments of shell. This covering, when it yields and crackles beneath the feet, indicates the presence of nitrate of soda, and the beds of this salt are found, on digging down a foot or two, overlaid generally by a stratum of common salt. Under the nitrate of soda is marl impregnated with saline matter and mixed with fragments of shells. The nitrate of soda, as quarried, is very variable in quality, some yielding not more than 25 per cent., and some 3 times as much of the genuine salt. It is mostly worked with the pick and shovel, but is sometimes so compact that the beds have to be blasted. Portions of the salt are pure white like loaf sugar, and others are colored reddish brown, lemon yellow, and gray. Its average composition was found by Dr. A. A. Hayes to be as follows: nitrate of soda, 64.98; sulphate of soda, 3.00; chloride of sodium, 28.69; iodide salts, 0.63; shells and marl, 2.60; total, 99.90. Mr. Blake states that nitrate of soda is very generally found along the W. coast of South America, impregnating the soil with other saline matter, and sometimes forming a thin crust upon the surface; but the only extensive beds known are in Tarapaca between lat. $19^{\circ} 30'$ and $20^{\circ} 45' \text{ S.}$, and long. $69^{\circ} 50'$ and $70^{\circ} 5' \text{ W.}$ The extraction and refining of the salt afford employment to a large part of the inhabitants of the province. It is taken to Iquique for shipment, and in 1837 the exportation amounted to 150,000 quintals, two thirds of which was to England, nearly one third to France. It is used for the manufacture of nitric acid, but its tendency to deliquesce renders it unfit for that of gunpowder. From its composition it should prove a valuable fertilizer. The crude salt is refined by Indians, directed by a Spanish major-domo. As it is quarried the workmen carry it in bags to the *officinas* or working places, which are always near by, and there it is broken up by women and children into small pieces.

These are thrown into copper kettles of the capacity of 50 gallons each, set within walls formed of cakes of salt. The kettles being about two thirds filled, water is added, and a strong fire is kept up till the water is saturated, when it is dipped into tubs to settle, and then the solution is transferred to shallow vats to crystallize. The residue, consisting principally of chloride of sodium and earthy matter, is thrown away, often carrying with it as much nitrate of soda as has been saved. The cost of the article at Iquique is reckoned for each 102 lbs. at 62 cents for labor in refining, 88 for fuel, 12 for tools and powder, and from 68 to 75 for transportation; or in all about \$1.87, to which should be added the general expense of the operation and the cost of bags for packing. The salt is reported to occur in large quantities in Pernambuco, west of Ipu, the formation extending 15 to 20 miles.—Of the metallic nitrates, the most important is that of silver, consisting of one equivalent of oxide of silver = 116, and one of nitric acid = 54. It is prepared by dissolving pure silver in nitric acid. The salt crystallizes in square tables, which are colorless and anhydrous. At 426° it fuses, and may then be cast into the crystalline sticks called lunar caustic, employed in surgery. At higher temperatures it is reduced to a metallic state. Nitrate of silver acts powerfully as a caustic, destroying the vitality of the flesh to which it is applied. Its solution in pure water remains colorless; but if the smallest quantity of organic matter be present, it is soon discolored when exposed to the light. It is thus a delicate test of the presence of organic matter. With albumen, fibrine, &c., it forms insoluble compounds, and may be employed to remove them from solution. The property of the solution to turn black by the reduction of the oxide of the silver, when the fluid is applied to organic substances and exposed to the light, renders it of important use for marking linen. The so called indelible ink is prepared for this purpose by dissolving one part of the salt and 4 parts of gum arabic in 4 parts of water, and adding a small quantity of India ink. The spot to be marked is first wetted with a solution of carbonate of soda and dried, and when written upon it is exposed to the sunlight. The spots may be removed by converting the silver with a few drops of iodine into the iodide, and dissolving this by a solution of hyposulphite of soda, or a dilute solution of caustic potash. A hair dye is also prepared with nitrate of silver by dissolving it in ether. From recent microscopical examinations very carefully made by Mr. T. J. Herapath of England, upon some obscure marks found upon the wrappers of mummies, there is reason to believe that the ancient Egyptians were acquainted with the compound nitrate of silver, and consequently with nitric acid.

NITRE. See NITRATES.

NITRIC ACID. See NITROGEN.

NITRITES. See NITROGEN.

NITROGEN (Gr. *νιτρον*, nitre, and *γενναω*, to produce), a simple gaseous body, so named from its being an essential element of nitric acid. It was first observed in 1772 by Dr. Rutherford of Edinburgh, and in 1775 shown by Lavoisier, and about the same time by Scheele, to be a constituent of the atmosphere. Lavoisier called it azote (Gr. *α* privative, and *ζωη*, life), on account of its not supporting respiration. It is inert in its properties, possessing neither taste, smell, nor color; and in the air, of which it forms about $\frac{1}{5}$ of the bulk, it appears to act the part of a diluent, tempering the too energetic qualities of the oxygen. (See ATMOSPHERE.) It is designated by the symbol N; its equivalent is 14; and its weight is 0.9713, air being 1.0000. It has never been liquefied under any pressure; it is not inflammable, and burning bodies are at once extinguished when immersed in it. It is sparingly absorbed by water, of which 100 parts take up $2\frac{1}{4}$ parts of the gas. Nitrogen is widely diffused among organic bodies. It exists in almost every vegetable substance, and forms a considerable part of what are known as the nitrogenous principles of food, as albumen, caseine, animal fibrine, and gluten. It is also an essential ingredient of some of the most potent medicines and poisons, as quinia, morphia, prussic acid, and strychnia. With hydrogen, in the proportion H, N, it forms the compound, ammonia; with carbon, cyanogen. Its compounds with oxygen, some of which will be noticed below, are also remarkable for their energetic character. These are 5 in number, as follows: 1, protoxide of nitrogen, NO; 2, deutoxide of nitrogen, NO₂; 3, nitrous acid, NO₂; 4, hyponitric acid, NO₂; 5, nitric acid, NO₃.—To procure nitrogen, it is necessary merely to deprive the air of its oxygen, which may be done by various methods, as by burning phosphorus in a bell glass of air; or by leaving a piece of phosphorus several days in the glass standing over water; or still better, by passing air through a tube partially filled with copper turnings heated to redness. It is also liberated when ammonia is decomposed by chlorine. Considering the inexhaustible sources of nitrogen in the atmosphere, it would be a great acquisition to agriculture could some method be devised of eliminating it with economy, and causing it to form with hydrogen ammoniacal compounds which could be used in the place of guano and other manures. It would also be highly advantageous could nitrogen, obtained from the same source, be applied to the preparation of cyanides, in the manufacture of Prussian blue. Attempts which have been made to effect these objects have failed, owing to the inertness of nitrogen, and the difficulties of causing it to enter into combination with hydrogen and with carbon. A method, however, has been recently announced by which MM. Marguerite and Sourdeval have attained these objects, making use of carbonate of barytes as the compound for fixing the nitro-

gen of the air, which they obtain in the form of cyanide of barium. From the cheapness of the natural carbonate and of the process, it is hoped that the method may prove of no little importance to the agricultural interest and to the manufacture of Prussian blue. The process is as follows. A mixture of carbonate of barytes with about 80 per cent. of iron filings and some coal tar and saw dust is calcined in an earthen crucible at a high temperature, which is kept up for some time. The greater part of the carbonate of barytes is converted into anhydrous barytes. A current of air is then made to traverse slowly the porous mass; and while its oxygen is converted into carbonic oxide as the air passes over incandescent charcoal, its nitrogen in the presence of the carbon and barium is transformed into cyanogen, and produces considerable quantities of cyanide. If the mixture be cooled while protected from the air, and washed with boiling water, an abundant precipitate of Prussian blue may be obtained by adding a salt of iron. The mixture is introduced into a cylinder, and a current of steam at a temperature below 800° C. is passed through it, the effect of which is to decompose the cyanide of barium, and cause the whole of its nitrogen to unite with the hydrogen of the steam to form ammonia. The cheap preparation of ammonia by this process suggests also the preparation of nitric acid from this product.—NITRIC ACID is the most important compound of nitrogen and oxygen, and the source from which the others named above are prepared. The acid was known to the alchemists, but its composition was first discovered by Cavendish in 1785. It is developed by the combination of the elements of the atmosphere when electrical sparks are passed through moist air; and it may almost always be detected combined with ammonia in rain water, especially after a thunder storm. It occurs in nature also in the mineral salts nitrate of soda and nitrate of potash, also known as nitre or saltpetre, which are the sources whence it is procured in large quantities. Its composition is: nitrogen 1 atom = 14, and oxygen 5 atoms = 40; or in 100 parts, nitrogen 28, oxygen 74. In this state uncombined with water it has been obtained by M. Deville in the form of brilliant, transparent crystals, derived from the right rhombic prism, which melt at 85° and boil at 118° F. With this exception the acid is known only in combination with water. In its most concentrated form, containing 85.72

of anhydrous acid and 18.28 of water, it has a density of 1.52, boils at 184° F., and freezes at about -40° . This is the so called fuming nitric acid, the composition of which is expressed by the formula, $\text{NO}_3 + \text{HO}$. By distilling it with much water a product of uniform composition is soon obtained, which boils at 253.4° , and contains 60 per cent. of pure acid and 40 per cent. of water; its density is 1.42; and its composition is represented by the formula, $\text{NO}_3 + 4\text{HO}$. This acid is more stable in character than the fuming acid, which tends to absorb water and pass into the other. Nitric acid of commerce, commonly known as aquafortis, is of various degrees of strength. It often contains $\frac{1}{2}$ water, and is of yellow color from the presence of nitrous acid or the other lower oxides of nitrogen. The acid free from other compounds is colorless. It possesses powerful corrosive properties, turning the skin and all animal matters that contain albumen yellow; and owing to this property it is sometimes applied to dyeing woollens yellow, and is also used as a cautery. From the readiness with which its oxygen is separated, nitric acid is much used for oxidizing other bodies. Most of the metals are thus easily attacked, and solutions of their oxides obtained. Some, as mercury, copper, and zinc, are acted upon with great violence by the concentrated acid; others, as tin and iron, are more readily oxidized by dilute acid. When the acid is mixed with $\frac{1}{2}$ its bulk of sulphuric acid and added to a few drops of an essential oil, as of turpentine, violent combustion and explosion take place. Red-hot charcoal is also thrown into brilliant combustion by the application of a little of the acid. When some vegetable substances, as lignine, starch, &c., are treated with concentrated nitric acid, definite compounds of peculiar character are produced without development of violent action. Paper is thus converted into a tough and highly inflammable material, and cotton into the so called gun cotton.—Nitric acid is obtained by distilling nitrate of potash or nitrate of soda with sulphuric acid. In the small way, equal parts of the salt and of strong oil of vitriol are introduced into a glass retort and heated; on the large scale, iron retorts are used, coated within in their upper parts with fire clay, and only half the weight of oil of vitriol is used. Nitrate of soda, being cheaper than nitre, and yielding 10 per cent. more nitric acid, is to be preferred. In the use of nitre the changes that take place are thus represented:

Nitric acid is often contaminated with sulphuric and hydrochloric acids, from which it

may be freed by redistilling, a little nitrate of silver being introduced to retain the sulphuric

acid and chlorine in the form of insoluble sulphate and chloride of silver. In the chemical and pharmaceutical works a table is given of the following form, furnished originally by Dr. Ure, by which the strength of the acid is seen by reference to its specific gravity:

Sp. gr.	Hydrated acid in 100.	Dry acid in 100.	Sp. gr.	Hydrated acid in 100.	Dry acid in 100.
1.50	100	79.700	1.27	46	86.603
1.47	89	70.983	1.24	41	82.677
1.45	83	66.155	1.20	35	87.595
1.41	78	58.181	1.17	30	83.910
1.368	68	50.211	1.11	20	75.940
1.3	51	40.647	1.048	8	6.876

Nitric acid is a most important agent in the chemical arts and in medicine. Some of its uses have already been referred to. It is a solvent of most of the metals, and combined with hydrochloric acid forms the *aqua regia* used for dissolving gold. Its solution of tin is used for the preparation of mordants in dyeing. In engraving it serves by its solvent property to etch the plates of copper. It is a powerful caustic in surgery, and is applied as a lotion to ulcers. In medicine it is used as a tonic and antiseptic, and, largely diluted with water, forms a beneficial drink in typhoid and other forms of fever. Its vapor is a powerful disinfectant, but probably inferior to chlorine for this purpose. Its use was introduced into the London hospitals by Dr. Carmichael Smyth, who received a reward of £5,000 from the British parliament. The vapor is generated as required by pouring sulphuric acid upon powdered nitre, which is placed in a saucer and this set upon hot sand contained in an earthen vessel. The concentrated acid is a most acrid poison.—The salts formed by nitric acid are called nitrates. They are all soluble in water; most of them fuse readily, and are decomposed at a high heat. The most important are the natural compounds employed for the manufacture of nitric acid. (See NITRATES.)—The other compounds of nitrogen and oxygen are of little importance compared with the acid just described. Nitrous acid (NO_2) is an unstable compound, known by its deep red fumes. These are generated by the action of diluted nitric acid upon copper clippings, the deutoxide or nitric oxide (NO), being first formed, which coming in contact with the air absorbs more oxygen. It is the nitrous acid in the fuming nitric acid of commerce which sometimes imparts to this red fumes. Its salts are called nitrites.—The lowest oxide of nitrogen, called the protoxide, and also nitrous oxide, possesses some properties of peculiar interest. The gas was first recognized by Priestley in 1776. It is obtained by partially deoxidizing nitric oxide by means of iron filings, or by exposing the salt nitrate of ammonia in a glass retort to a temperature of about 420° . To obtain pure gas, the salt should be free from chlorine, and the temperature not so high as to produce white vapors. Nitrous oxide has a sweet taste, but no odor or color. Its density is 1.527; it liquefies

under a pressure of 50 atmospheres at 45° , and at still lower temperature is solidified. It supports combustion, giving even increased brilliancy to the flame of burning bodies. Its chief interest is in its effect upon the human system when respired, which has given to it the names of exhilarating and laughing gas. It produces intoxicating sensations, generally of a pleasant nature, often leading to wild and extravagant actions. The effect usually passes off in a short time after inhaling the gas; but in cases of individuals liable to a rush of blood to the head, or otherwise affected with disease, it has produced serious results. Only pure gas should ever be used for this purpose, and this unmixed with common air. This peculiar quality of nitrous oxide was first observed by Sir H. Davy, who published an account of the gas in 1800. The late Mr. Horace Wells of Connecticut experimented with it as an anæsthetic agent before the properties of ether for this use were discovered. Water charged with the gas has been applied in medicine as a tonic, stimulant, and diuretic. In cases of dogs asphyxiated or poisoned, it has been found when injected into the bowels to act as an antidote and revivifier. (See "Boston Medical and Surgical Journal," vols. xli. and xlii.)

NITROUS ACID. See NITROGEN.

NITROUS OXIDE. See NITROGEN.

NITZSCH, KARL IMMANUEL, a German theologian, son of Karl Ludwig Nitzsch, superintendent-general of the university of Wittenberg, born in Borna, Sept. 21, 1787. He was educated at Wittenberg, and studied theology, embracing the opinions of Schleiermacher and the more liberal school. In 1817 he became professor in the new theological seminary at Berlin. In 1822 he accepted a position in Bonn as professor and university preacher; and in 1847 went to Berlin as the successor of Marheineke, where he was professor, university preacher, and member of the high consistory. He is the author of a number of smaller treatises on dogmatics, &c.; and among his larger works are: *System der Christlichen Lehre* (Bonn, 1829; 6th ed., 1851; translated by Montgomery, Edinburgh, 8vo., 1849), and *Praktische Theologie* (vols. i. and ii., Bonn, 1847-'8).—GREGOR WILHELM, a German philologist, brother of the preceding, born in Wittenberg, Nov. 22, 1790. He studied philology under Lobeck in 1810, enlisted as a volunteer in the war of liberation, was present at the battle of Leipsic, and after his return became co-rector of the Wittenberg lyceum. In 1815 he exchanged this situation for that of sub-rector in Zerbst, in 1820 returned to Wittenberg, and in 1827 was appointed professor of ancient literature at Kiel, where he devoted himself especially to the philological department. In June, 1852, the offices and salaries of Nitzsch and 7 other professors were declared forfeited; but in August of the same year he was appointed professor of archæology in Leipsic. He is distinguished as the able opponent of F.

A. Wolf's theories in regard to the poems of Homer. His chief work, *Die Sagenpoesie der Griechen* (Brunswick, 1852), and nearly all the rest of his numerous writings, are devoted to the discussion of that question, and to the general criticism of the Homeric poems.

NIVERNAIS, an ancient province of France, now mostly comprised in the department of Nièvre. It was situated near the centre of the kingdom, and bounded N. E., E., and S. E. by Burgundy, S. and S. W. by Bourbonnais, W. by Berry, and N. W. by Orléanaise. It was subdivided into the Vaux or valleys of Nevers, the Donzais, the valleys of the Yonne, of Montenoison, and of the Amognes, the country between the Loire and the Allier, Bazois, and Morvan. Its ancient inhabitants were the *Ædui* and *Sequani*, and it was afterward subject to the Franks. In the 10th century it became independent. The capital was Nevers.

NIZAM, and **NIZAM'S TERRITORY**. See **HYDERABAD**.

NOAH, a patriarch in biblical history, son of the second Lamech, and the 10th in descent from Adam. It is related in Genesis that he was chosen by Jehovah on account of his piety to be the father of the new race of men that should people the earth after the flood. He was warned by God of the approaching deluge, and built an ark under the Almighty's directions, into which he entered, with his family and all kinds of animals. The flood came, and all living things perished save those preserved in the ark. After the waters had subsided and the dry land began to appear, the ark rested on Mount Ararat, in Armenia, where Noah offered a sacrifice to the Lord, who accepted it and made a covenant with him, ratifying it by the sign of a rainbow in the clouds. Noah then "began to be a husbandman;" he planted a vineyard, "and he drank of the wine and was drunken, and was uncovered within his tent." His son Ham ridiculed the exposure of his father, but his two other sons, Shem and Japheth, with filial respect covered him with a garment. When Noah awoke and knew what had happened to him, he blessed Shem and Japheth, but cursed Canaan, the son of Ham, prophesying of him that he would be a servant of servants to his brethren. By some there is thought to be a coincidence between the history of Noah and the traditions of many other nations, viz.: the Xisuthrus of the Chaldeans, the Phrygian Noë, the Manes of the Lydians, and the Deucalion of the Greeks. (See **DELUGE**.)

NOAH, MORDECAI MANUEL, an American author and journalist, of Jewish origin, born in Philadelphia, July 19, 1785, died in New York, March 22, 1851. He early attempted to learn a mechanical business, but left it for the study of law, literature, and politics. He removed to Charleston, S. C., and in 1811 was appointed by President Madison U. S. consul to Riga, and two years afterward consul to Tunis, with a mission to Algiers. The vessel in which he made the passage out was taken by a British

man-of-war, and Mr. Noah was detained a prisoner in England for several weeks. On returning in 1819, he published a volume entitled "Travels in England, France, Spain, and the Barbary States, from 1818 to 1815" (8vo., New York). Taking up his residence in New York, he became editor of a democratic journal called the "National Advocate," and was subsequently elected sheriff of the city and county. In 1826, the "Advocate" having been given up, he began the publication of the "New York Enquirer," which was afterward united with the "Morning Courier" to form the "Courier and Enquirer." In 1834 he began a daily newspaper called the "Evening Star," which was finally merged in the "Daily Times." In July, 1842, he founded another daily, called the "Union;" and in 1844 he commenced the "Weekly Messenger," which was soon merged in the "Sunday Times," and for which he wrote until a short time previous to his death. Major Noah, as he was always called, at one time endeavored to form a settlement of the Jews on Grand island in the Niagara river; and in his memorial to the legislature of New York in 1820 for its purchase, he recounted the indignities that nation had endured, the benefits that had accrued to Spain, Portugal, France, and Germany from their commercial enterprise, and the advantages that would result to the United States if his people could exchange "the whips and scorns of Europe, Asia, and Africa for the light of liberty and civilization" in America. The scheme failed, however, as the European rabbis were not satisfied as to his claim to be the leader of Israel; and no trace of the "city" was left but a monument of brick and wood, with the following inscription, preceded by a text from Deuteronomy: "Ararat, a city of Refuge for the Jews. Founded by Mordecai M. Noah, in the month of Tisri, 5586 (Sept. 1825), and in the 50th year of American Independence." This monument has since disappeared. He held for a brief period, by appointment of the governor, the office of judge of the court of sessions, was at one time surveyor of the port of New York, and at various times held other appointments in the gift of his political friends. "In 1845 he delivered a discourse upon the restoration of the Jews, and published a collection of his newspaper essays, entitled "Gleanings from a Gathered Harvest" (12mo., New York). He also published a "Translation of the Book of Jasher" (8vo., New York, 1840), and was the author of several successful dramas.

NOAILLES, **HOUSE OF**, a noble French family of Limousin, tracing its origin back to the 10th century. Its most celebrated members are the following: I. **ANTOINE**, born in 1504, died in 1562. He served as a soldier and diplomatist under Francis I., distinguished himself at the battle of Ceresole in 1544, was created grand admiral of France by Henry II. on his accession to the throne, was sent on a mission to England, and negotiated the truce

of Vauxcelles in 1556. His *Négociations en Angleterre*, as well as those of his brother Philippe, bishop of Acs, and one of the most skilful diplomats of his time, were published by the abbé Vertot (8 vols. 12mo., 1768). II. LOUIS ANTOINE, born in 1651, died in 1720. He became archbishop of Paris in 1695 and cardinal in 1700. In the controversy between Bossuet and Fénelon, he at first tried to act as a mediator, and then sided with the former. His want of decision in the matter of Quesnel's doctrines and the bull *Unigenitus*, which he subscribed only a few months before his death, kept up religious agitation in his diocese; but he was a man of unbounded charity, and during the dreadful winter of 1709 sent all his silver plate to the mint, and distributed the price among the poor of Paris. He rebuilt the archiepiscopal palace, and adorned the cathedral of Notre Dame. III. ANNE JULES, elder brother of the preceding, a duke and peer of France, born in 1650, died in 1708. He served against the Spaniards in 1667, and during the war against Holland in 1672. Being appointed governor of Languedoc, he evinced great lenity toward the Calvinists when the edict of Nantes was revoked by Louis XIV. in 1685. In 1689 he was placed at the head of the French army sent to aid the revolted Catalans, took several Spanish towns, and defeated the Spanish royalists in 1694. IV. ADRIEN MAURICE, son of the preceding, born in 1678, died in 1766. He first served in Spain under his father, and under the duke of Vendôme, accompanied Philip of Anjou when he went to Spain to take possession of the crown, and rendered valuable services to that prince. Louis XIV. bestowed upon him the rank of duke and peer of France. On the death of Louis in 1715, he was appointed one of the council of regency. In 1718, under Philip of Orleans, he became president of the council of finance, compelled the dishonest farmers of the public revenue to make restitution, and opposed the financial system of John Law. He resumed military service in 1733, won the rank of marshal at the siege of Philippsburg, and expelled the German troops from Worms in 1734. During the war of the Austrian succession he was defeated at Dettingen, in 1743, by George II. of England. He then entered the council of state, and as ambassador to Spain in 1746 effected a reconciliation between the two courts. His *Mémoires* were published by the abbé Millot (6 vols. 12mo., 1777). V. LOUIS MARIE, grandson of the preceding, born in 1756, died Jan. 9, 1804. Being a younger son, he bore the title of viscount. He joined the French expedition which sailed to assist the Americans in the war of the revolution, and fought with great gallantry in several engagements. He took the popular side in the French revolution of 1789, proposed the renunciation by the nobles of all their feudal privileges (Aug. 4), and laid before the constituent assembly a plan for the organization of the army, which was adopted.

On the king's flight to Varennes he took the oath to the nation, and served in a military capacity on the northern frontier; but on the imprisonment of the king he resigned his commission and retired to England. After the 18th Brumaire he returned to France, reentered the army, was sent as brigadier-general to St. Domingo, was wounded in capturing an English sloop of war, and was taken to Havana, where he died. VI. PAUL, duke of, born Jan. 4, 1802. The offspring of a younger branch of the family, he inherited the title of duke from his uncle, who died in 1823. He took his seat in the chamber of peers in 1827, and kept it after the revolution of 1830, though he was an adherent of the exiled Bourbons. In 1848 he retired to private life. He was elected to the French academy, as successor to Châteaubriand. He is the author of a *Histoire de Mme. de Maintenon* (2 vols. 8vo., 1848), and an *Essai sur la maison royale de St. Cyr*, first privately printed and afterward published in an enlarged form in 1856.

NOBILITY (Lat. *nobilitas*), a class of persons elevated by hereditary rank above the mass of the people. The origin of this institution is very remote, as it is found existing among almost every people at the dawn of history. The earliest nobility seems to have been priestly in character, as for instance the Brahmins of India. Among the Romans, the patrician families who formed the nobility had for a long period the exclusive right to exercise priestly functions. The ancient Germans, the Franks, Saxons, Normans, Danes, Swedes, and other northern nations, seem at first to have had no other hereditary nobility than the members of the royal family, who were supposed to be descendants of Odin and other deities. The present nobility of Germany and Scandinavia was founded chiefly by military chieftains in the middle ages. Hereditary nobility is said to have been confirmed in France by Hugh Capet toward the close of the 10th century, and it was fully established in England by William the Norman in the 11th century. Sir James Lawrence, in his "Nobility of the British Gentry," says that arms are the criterion of nobility, and that whoever has a shield of arms is a nobleman. In the northern and eastern countries of Europe, Germany, Sweden, Denmark, Russia, Poland, and Hungary, the titles of nobility descend to all the male posterity and to all the unmarried females of the family; but in France, Spain, Portugal, and Great Britain, the titles descend only according to the rules of primogeniture. In Great Britain the nobility consists of the five ranks of duke, marquis, earl, viscount, and baron. Baronets, knights, and the younger sons of peers are classed only among the gentry, while on the continent they would be held as noble.

NOBLE. I. A S. E. co. of Ohio, drained by Wills, Seneca, and Duck creeks; area, about 400 sq. m. It was formed in 1851 from Morgan, Monroe, and Guernsey counties. It has an

undulating and hilly surface, and is well timbered and fertile. It contains quarries of building stone and extensive coal mines. Capital, Sarahsville. II. A. N. E. co. of Ind., drained by Elkhart and Tippecanoe rivers; area, 480 sq. m.; pop. in 1860, 14,887. The productions in 1850 were 206,295 bushels of Indian corn, 69,802 of wheat, 56,715 of oats, 21,625 lbs. of wool, and 2,487 tons of hay. There were 5 churches, and 1,844 pupils attending public schools. Capital, Albion.

NOBLE, SAMUEL, an English clergyman and author, born in London, March 4, 1779, died there, Aug. 27, 1858. He was the son of Edward Noble, a bookseller and author, was taught Latin and the ordinary branches of a good English education, and at the age of 14 was apprenticed to an engraver. In the last year of his apprenticeship he became acquainted with the writings of Swedenborg, and in March, 1801, was baptized into the New Jerusalem church. He immediately took an active part in spreading a knowledge of the doctrines of the church, and in 1810 was one of the founders of the London society for printing and publishing the writings of Swedenborg, of which he was for many years secretary. In that capacity he superintended through the press every work which it published, beside making several translations and revisions. In 1812 he assisted in founding the "Intellectual Repository" (monthly), the leading Swedenborgian journal of Great Britain, of which he was editor for 28 years; he was also a very large contributor to it. During this period he steadily pursued his profession of engraver, in which he attained a high rank and received a considerable income. In 1820 he was ordained a minister of the New Jerusalem church, for which he had prepared himself by diligent study of the Hebrew and Greek Scriptures, and succeeded Dr. Churchhill as pastor of the Lisle street society, with which he remained connected till his death. He soon became distinguished as a preacher. In 1824 he delivered a course of lectures in vindication of the Scriptures from infidel objections, which he afterward enlarged and published under the title of "Plenary Inspiration of the Scriptures." Subsequently he delivered at Norwich another course of lectures, which was also published under the title of "An Appeal in behalf of the Doctrines of the New Church." These two works are now ranked among the standard publications of the New Jerusalem church, and have passed through several editions in England and the United States. In 1846 he published a volume of lectures on the "Important Doctrines of the True Christian Religion," and in 1848 a volume of sermons entitled "The Divine Law of the Ten Commandments Explained according to both its Literal and its Spiritual Sense." His last work was a new translation of Swedenborg's "Heaven and Hell."

NODAWAY, a N. W. co. of Mo., bounded N. by Iowa and W. by the Nodaway river, and

drained by the Little Platte and the One Hundred and Two river; area, 710 sq. m.; pop. in 1856, 4,772, of whom 148 were slaves. The productions in 1850 were 167,118 bushels of Indian corn, 10,208 of wheat, 16,485 of oats, 7,487 of wool, and 64 tons of hay. Capital, Maryville.

NODDY, the common name of the birds of the tern family included in the genus *anous* (Leach). The bill is longer than the head, strong, with the culmen curved gradually to the acute tip, and a distinct angle to the lower mandible; wings long and pointed, the 1st quill the longest; tail long and graduated; tarsi rather short and slender; toes long, and united by a full web; hind toe long and slender; claws curved and sharp. The only species on our coast is the *A. stolidus* (Leach), 16 inches long, with an extent of wings of 32 inches, the bill 1½, and the weight 4½ oz.; the front of the head is grayish white, with a black spot over and before the eyes; the rest of the plumage sooty brown, except the primaries and tail, which are brownish black; the bill is black, the iris brown, and the legs and feet dull brownish red. They are found in the gulf of Mexico from Texas to the Atlantic, whence they proceed early in May to the Florida keys to breed; the nests are made of twigs and grass on bushes or low trees, several in company; the eggs are 3, 2 by 1½ inches, reddish yellow with dull red and purplish spots and patches, and are considered excellent as food. Several other species are described, inhabiting the tropical seas, where they are seen very far from land. They generally breed in large flocks, and in some places deposit their eggs on the bare rock. They are excellent swimmers and rapid fliers; not seeing very well at night, they are frequently caught at this time, when they have alighted on the spars of passing vessels, they are less shy than other terns.

NODE, the point at which the orbit of a planet or comet intersects the ecliptic, or at which the orbit of a satellite cuts that of its primary. The ascending node is where the planet, comet, or satellite crosses from S. to N., the descending node where it crosses from N. to S.; and a line joining the two is called the line of the nodes.

NODIER, CHARLES, a French writer, born in Besançon, April 9, 1783, died in Paris, Jan. 26, 1844. When he was scarcely 18 years old he published a disquisition upon the "Use of Antennæ in Insects," in which he attempted to show a connection between those organs and the sense of hearing. He went to Paris in 1801, and published several novels and miscellaneous poems; but having written a satirical ode entitled *La Napoléone*, in which, two years before the establishment of the empire, he denounced the imperial aspirations of the first consul, he was for a few months incarcerated at Ste. Pélagie. Returning to Besançon after his release, he became a proof reader, and afterward a print colorist. Through the

influence of Jean Debry, prefect of Doubs, he was appointed professor of literature at Dôle, whence he removed to Laybach, where he held the post of public librarian, and afterward edited a newspaper. The events of 1814 recalled him to France; he welcomed the return of the Bourbons, and advocated their cause in various newspapers, chiefly in the *Journal des débats*, to which he was for a while attached as a regular contributor. In 1824 he was appointed librarian at the arsenal of Paris, and his rooms became the rendezvous of a brilliant circle of friends, including many of the young writers of the day. This period was the zenith of his literary fame; and although the French academy was decidedly hostile to the so called romantic school toward which he had a leaning, he was in 1838 elected a member of this learned society. He was distinguished at once as a scholar and a poet, an entomologist and a publicist, a grammarian, a bibliographer, and a novelist. His works are very voluminous.

NOË, AMÉDÉE. See CHAM.

NOEL, BAPTIST WHOTHESLEY, an English clergyman, born July 10, 1799. He is a son of Sir Gerard Noel Noel, and a younger brother of the earl of Gainborough. He was educated at Trinity college, Cambridge, and was for many years a prominent clergyman of the established church, being one of the chaplains of the queen, and occupying the pulpit of St. John's, Bedford row, London, a proprietary chapel. He was also an active promoter of city missions, and other organizations for the benefit of the poor. In 1849 he withdrew from the established church, and joined the Baptists. Since his change of sentiment he has been pastor of John street chapel, Bedford row. He is still active in the promotion of objects of benevolence, and his eloquence has given great weight to his advocacy of measures of charity and reform. He has recently been engaged in a movement for the reformation of prostitutes. His published works are: "Sermons preached at the Chapels Royal of St. James and Whitehall;" "Notes of a Tour in Switzerland in the Summer of 1847;" "The Gospel of the Grace of God, illustrated in a Series of Meditations;" "Christian Missions to Heathen Nations;" "Case of the Free Church in Scotland;" "Essays on the Union of Church and State" (1848); "Essay on Christian Baptism" (1849); "Essay on the Eternal Act of Baptism" (1850); "Letters on the Church of Rome" (1851); and "Protestant Thoughts in Rhyme."

NOLA, a city of Naples, in the province of Terra di Lavoro, about 15 m. E. N. E. from Naples, and 7 m. N. from Mt. Vesuvius; pop. about 12,000. It is one of the oldest cities of Campania, and was powerful enough in 327 B. C. to send 2,000 soldiers to the aid of Palæopolis and Neapolis against the Romans, to whom it became subject in 318. Hannibal made three attempts to take possession of Nola, but was each time repulsed by Marcellus. Immense numbers of ancient coins have

been discovered at Nola, and its sepulchres have supplied innumerable Etruscan vases to the museums of Europe; and in its own museum is preserved the celebrated Oscan inscription called the *cippus Abellanus*. The emperor Augustus and his general Marcus Agrippa both died in the town; and it was the birthplace of Giordano Bruno. St. Paulinus was bishop of Nola in the 5th century, and to him is attributed the first introduction of church bells; whence the names *nola* and *campana* applied to them in the middle ages. It is still an episcopal see.

NOLLE PROSEQUI (Lat., to be unwilling to prosecute), a law term derived, as most law terms are, from those ancient days when all law proceedings and records were in Latin. It meant that the plaintiff declared in court and entered upon the record that he would no longer prosecute his suit. In civil cases, this is superseded in modern times by a nonsuit; but when a plaintiff enters a nonsuit, especially if he does this by order of court, he is still sometimes said to be "nol. pros'd." *Nolle prosequi* is very common in criminal cases. It is entered by the officer who acts for the government, when, from insufficiency of evidence or other reasons, he is unwilling to press the trial any further. He may do this, generally, at any stage of the proceedings. But it puts the defendant, or accused party, to this disadvantage: if he has a verdict in his favor, he cannot be tried again for that offence; but if *nolle prosequi* is entered, he may be indicted and tried again at any time for the same offence. He would prefer therefore a verdict in his favor; but this he ought not to have, if he would escape now by a merely accidental absence of testimony. On the contrary, if it be obvious that he could be fairly tried now, and would probably be acquitted, it would not be just to permit the government to hold this power of accusation and trial over him indefinitely. In some of the states there are statutes, or rules of court, intended to meet this difficulty; and practical mischief seldom arises from it, as a *nolle prosequi* would not be entered by government against the wishes of a defendant, without unquestionable reasons.

NOLLEKENS, JOSEPH, an English sculptor, born in London, Aug. 11, 1787, died April 23, 1828. He was the son of Francis Joseph Nollekens, a Flemish painter of some repute settled in London, and acquired the elements of his art in the studio of the sculptor Scheemakers, where he labored with great assiduity, repeatedly gaining prizes offered for competition by the society of arts. In his 28d year he visited Rome, and during an active career there of 10 years laid the foundation of the great reputation he subsequently enjoyed, and added considerably to his pecuniary resources, which had previously been meagre. Garrick and Sterne were among his first sitters, and his bust of the latter in terra cotta he always regarded as one of his most successful works.

He also executed a number of groups and ideal pieces of the ordinary classic type, a good specimen of which was the "Mercury and Venus chiding Cupid," and conducted a lucrative business in repairing and vamping up fragments of antique statuary. Returning to London in 1770, he opened a studio in Mortimer street, and, aided by the patronage of George III., who sat to him for his bust, and other influential persons, he embarked in a professional career of unvarying prosperity, which ended only with his life. His strength lay in his portrait busts, which were distinguished by accuracy of likeness, a refined expression, and great delicacy of execution. He accordingly confined himself chiefly to this branch of his art, producing during the last 50 years of his life an immense number of heads, and numbering among his sitters Pitt, Fox, the prince of Wales, Dr. Johnson, the duke of York, Lords Castlereagh, Erskine, Egremont, and Liverpool, Canning, Percival, Benjamin West, and other eminent men. He also found leisure to work out a number of Venuses, Dianas, Bacchuses, and similar subjects, highly esteemed in their time, but too deficient in imagination and too evidently imitated from the antique to command much attention at the present day. Of this class of pieces he considered his "Venus anointing her Hair" his *chef d'œuvre*. He occasionally essayed monumental sculpture with success, and executed a well known statue of Pitt for Cambridge. He was of penurious habits, and amassed a fortune estimated at £200,000, the greater part of which was left to his friends Francis Palmer and Francis Douce, the antiquary. In 1772 he was elected a member of the royal academy. His life was written by his pupil, J. T. Smith (3 vols., London, 1828).

NOLLET, JEAN ANTOINE, abbé, a French natural philosopher, born at Pimpré, near Noyon, Nov. 17, 1700, died in Paris, April 25, 1770. He studied for the church, and received deacon's orders, but devoted his life to science. In conjunction with Du Fay he made electricity the special object of his researches, being assisted by Réaumur, who gave him free access to his laboratory. He asserted that by the agency of electricity he had succeeded in making plants grow faster and produce shoots earlier. In 1739 he was elected to the academy of sciences, was subsequently appointed to a chair of experimental philosophy in the college of Navarre, and was afterward successively teacher of physics and natural history to the princes of the royal family, and professor in the military schools at La Fère and Mézières. His lectures and writings aided greatly in spreading the taste for scientific studies in France.

NOMENCLATURE, CHEMICAL, the vocabulary of terms used in chemistry. For a science which, like chemistry, seeks to study the composition of all material substances and to classify these in accordance with the characteristic properties of their components, the importance of a uniform system of nomenclature must be

apparent to every one. In truth, few events are recorded in the history of chemical science which have exerted a more beneficial influence upon its progress than the adoption of the admirable method of nomenclature brought forward by Guyton de Morveau in 1782, modified by a committee of the French academy, of which Lavoisier was chairman, in 1787, and published under the auspices of the academy in a volume entitled *Méthode de nomenclature chimique* (Paris, 1787). Several chemists had previously endeavored to improve upon the indefinite and irrational names adopted by the alchemists, and had perceived the importance of designating compound bodies by the names of their components; but no satisfactory general system had till then been devised. As has already been mentioned in the article CHEMISTRY, the circumstances attending the introduction of Guyton de Morveau's system were such that it soon came into general use. No better evidence of its original merit can be offered than the fact that it is still employed, having undergone no essential change, although the domain of the science has been immensely increased since its introduction, and in spite of the great difference between the theoretical views now entertained and those advanced by its founders.—It should be mentioned at starting that the system of nomenclature here to be described is so intimately connected with certain theoretical views of the constitution of compound bodies, that any treatise upon it must become also in a measure a description of the methods of classification upon which it depends. The main feature of the system consists in forming in a simple and uniform manner the name of any and every compound from the names of the substances of which it is composed. The elements alone are subject to no rule, their names depending entirely upon the choice of the discoverer. It is true that the framers of the nomenclature sought in several instances to express some one prominent property of the element by means of its name, as in the case of oxygen (Gr. *οξύς*, acid, and *γεννᾶω*, to generate), which was thought to be "a principle necessary to acidity," or hydrogen (Gr. *ὕδωρ*, water, and *γεννᾶω*). But these attempts were confined to the elements which at that time had been recently discovered; the common names of all the well known metals, alkalies, &c., having been retained. Of the elements which have since been discovered, some have been named in allusion to striking peculiarities, as chlorine (*χλωρός*, green), iodine (*ιώδης*, violet), &c. For the most part, however, names devoid of any chemical significance have been chosen, the propriety of which course is now very generally admitted by chemists. In choosing the name of an element, it is important only that it shall be well adapted to the formation of compound names. In accordance with Davy's suggestion, the names of the more recently discovered metals have received a common termination *um*, as

potassium, platinum, &c. The idea of applying some one uniform termination to each of the members of a natural group had previously been suggested by Bergman, from whom it was adopted also by the French nomenclaturists, who proposed that the names of metals should all terminate in *e*, as *platine*, *cuiore*, &c. The names of another class of elements terminate in *ine*, as chlorine, iodine, &c.—The elements are divided into two classes, metals and non-metallic bodies (metalloids). The metals all possess certain analogous characteristic properties. The class of metalloids, however, includes several quite distinct groups of elements. As a rule, those elements whose chemical properties are much alike rarely unite with each other to form well defined chemical compounds; thus the products, termed alloys, obtained by melting a metal with another which closely resembles it, are in many cases mere isomorphous mixtures, the components of which are united with but feeble affinity. It should be mentioned in passing that these cases of weak affinity have always been so many stumbling blocks in the existing system of nomenclature, and have given rise through it to one of the greatest faults of the present chemical epoch, viz.: a tendency to ignore altogether, or at best to keep out of view, all compounds which are not clearly defined, fixed, and so to say intelligible; in short, all those which cannot be readily named and classified in accordance with existing theories; and very many such have been observed even in the domain of the so called inorganic chemistry. On the other hand, the strongest affinities are generally exerted between bodies the chemical properties of which exhibit the greatest differences.—When two elements of unlike properties combine with each other, the product is termed a binary compound. Binary compounds are divided into three great classes, acids, bases, and indifferent bodies. The last have but little chemical activity. Acids and bases, however, possess unlike properties, and, although they do not combine with the elements, still manifest a great disposition to unite one with the other. Ternary compounds, or salts, are thus formed. When an acid has taken up as much of any one base as it can dissolve, it is said to be saturated, the dissimilar properties of the acid and base having neutralized each other. The resulting salt possesses new properties unlike those of its components, having usually but little affinity for other substances; but some salts can unite with others to form quaternary bodies (double salts). The distinctive properties of these several classes are by no means absolute. Indeed, there are many bodies which, according to circumstances, act either as acids or as bases: as acids when brought in contact with strong bases, and as bases toward strong acids. Those acids which are soluble in water are distinguished by their power of changing the blue color of a solution of litmus to red. Bases, on the contrary, reproduce the blue color of litmus which

has been reddened by an acid. Bodies which are insoluble in water are classified in accordance with the combinations which they form with other bodies known to be acids or bases. The most characteristic salts have but little or no action on red or blue litmus, the acid and basic qualities of their components having been entirely neutralized by combination. There are, however, many exceptions to this; and in general any definite compound produced by the combination of an acid and a base is termed a salt. When a solution of a salt is subjected to a weak galvanic current, the acid and base of which it consists are separated from each other; the acid collects at the positive pole of the battery, the base at the negative pole. On the theory that like electricities repel, while unlike attract each other, it is evident that the particles of matter which are attracted to the positive pole ought to possess negative electricity, while those attracted to the negative pole should be positively electrified. The base is therefore often called the electro-positive and the acid the electro-negative constituent of the salt. The character of the respective constituents of a salt may hence be exhibited by submitting the latter to the action of galvanism. The same rule applies also to all binary compounds which can be electrolyzed.—In view of the great prominence which oxygen had attained in consequence of the experiments of Lavoisier, and of the fact that most of the acids and bases known to the founders of the chemical nomenclature contained it, or were thought to contain it, as one of their constituents, it is not surprising that especial importance was attached to this element. Indeed, its compounds form the basis of the system. The binary compounds of oxygen are, with the exception of a few indifferent substances, either bases or acids. They are called oxides, the termination *ide*, which is indicative of combination, being added to the first syllable of oxygen. Although the term oxide is generic, and would, strictly speaking, apply with equal force to any compound of oxygen with an element, it is nevertheless usually restricted to those compounds which are destitute of acid properties, viz., to the bases and indifferent bodies. Its acids are often called oxy-acids. The name of any particular oxide is formed by adding the name of its other element to this generic term; thus, the base formed by the union of oxygen and lead is called oxide of lead, that containing oxygen and potassium, oxide of potassium, &c. Lead and potassium are in these instances electro-positive elements, oxygen being electro-negative in regard to them. As a general rule, the name of the electro-negative constituent of a compound determines its genus, while that of the electro-positive constituent defines the species. The names of the basic compounds which oxygen forms with metals whose names end in *um* are often made to terminate in *a*; thus, instead of oxide of sodium and oxide of barium, the terms *soda*

and baryta are used. Oxide of calcium furnishes the most striking exception to this rule, the common name lime being used instead of calcia. Oxygen usually combines with an element in more than one proportion, forming several bases. To distinguish these, the prefix *proto* (Gr. *πρωτος*, first) is applied to the oxide in which one equivalent of oxygen is united with one equivalent of the element. An oxide containing less than one equivalent of oxygen to one of the other element is called a sub-oxide (Lat. *sub*, under). The prefix *sesqui* (one and a half) denotes a compound in which the oxygen is to the other element in the ratio of 3 to 2; *deuto* (Gr. *δευτερος*, second) or *bin* (Lat. *binus*, two), an oxide containing two equivalents of oxygen; and *trito* (*τριτος*, third) or *ter* (*τερτιος*, three), an oxide containing three equivalents of oxygen to one of the other element. The base containing the largest amount of oxygen is often called the peroxide (*υπερ*, above); thus, three compounds of the metal manganese and oxygen are distinguished as follows:

Protioxide of manganese contains	{ 1 eq. of manganese, 1 eq. of oxygen.
Sesquioxide of " "	{ 2 eqs. of manganese, 3 eqs. of oxygen.
Bin- dent- or per- } oxide of " "	{ 1 eq. of manganese, 3 eqs. of oxygen.

At the time when the nomenclature was framed, it was believed that only two acid compounds could be formed by the combination of oxygen with another element. These were distinguished from each other by causing the name of the other element to terminate in *ic* for the combination containing the larger proportion of oxygen, and in *ous* for the compound containing less oxygen, the word acid being added in each case to the words thus formed. For example, two compounds of sulphur and oxygen are respectively:

Sulphurous acid, composed of	{ 1 eq. of sulphur, 3 eqs. of oxygen.
Sulphuric acid, " "	{ 1 eq. of sulphur, 3 eqs. of oxygen.

A compound of carbon and two equivalents of oxygen is carbonic acid, &c. It was afterward discovered that oxygen could unite with several elements in more than two proportions to form acid compounds. The prefix *hypo* (*υπο*, under) was therefore resorted to; it indicates an acid containing less oxygen than the one to whose name it is prefixed. In like manner the prefix *hyper*, or simply *per* (*υπερ*, over, above), denotes an acid containing more oxygen than the one to whose name it is attached. Thus, 5 acid compounds of oxygen and chlorine are known:

Hypochlorous acid, composed of	{ 1 eq. chlorine, 1 eq. oxygen.
Chlorous acid, " "	{ 1 eq. chlorine, 3 eqs. oxygen.
Hypochloric acid, " "	{ 1 eq. chlorine, 4 eqs. oxygen.
Chloric acid, " "	{ 1 eq. chlorine, 5 eqs. oxygen.
Perchloric acid, " "	{ 1 eq. chlorine, 7 eqs. oxygen.

Of the compounds which an element may form with oxygen, those containing the larger num-

ber of equivalents of the latter are usually acids; those containing but few equivalents of oxygen are bases; while not unfrequently the intermediate degrees of oxidation are indifferent bodies. Thus, of the oxides of manganese just referred to, the proto- and sesquioxides are bases, and the bin- (or per-) oxide is an indifferent body; there are also two compounds containing more oxygen which are acids, viz.:

Manganic acid, containing	{ 1 eq. manganese, 3 eqs. oxygen.
Permanganic acid, " "	{ 2 eqs. manganese, 7 eqs. oxygen.

The compounds which oxygen forms with the metals are, however, for the most part bases, those with the metalloids acids.—Many of the binary compounds of sulphur are analogous to those of oxygen. They are termed sulphides (formerly sulphurets), and as a rule correspond with the oxides. Like the latter, they may be classed as acids, bases, and indifferent bodies. Members of the first two classes, like the oxy-acids and bases, unite with each other to form sulpho-salts. They have, however, comparatively little affinity for the other elements, or for compounds not containing sulphur. The sulphur bases and the indifferent sulphides are distinguished by the same prefixes as the oxides. Thus, the three sulphides of iron are termed respectively: protosulphide of iron, symbol FeS ; sesquisulphide of iron, Fe_2S_3 ; and persulphide of iron, FeS_2 . The sulphur acids are named by prefixing the term *sulpho* to the name of the corresponding oxygen acid. Thus, the compound of carbon and sulphur analogous to carbonic acid, is called sulpho-carbonic acid. The binary compounds of chlorine and of several other elements are named in a similar manner. Thus, with the other elements, oxygen forms oxides; sulphur, sulphides (sulphurets); chlorine, chlorides; bromine, bromides; iodine, iodides; fluorine, fluorides; phosphorus, phosphides (phosphurets); carbon, carbides (carburets); nitrogen, nitrides, &c. When several chlorides, bromides, iodides, or fluorides of any one metal occur, they are distinguished by the same prefixes as the oxides. The binary compounds of these elements are, however, usually regarded, not as acids and bases, but, like the ternary oxygen compounds, as salts. This exception is one of the fruits of the too hasty assumption by the founders of the nomenclature, that oxygen was the universal acidifying principle—an error which lies at the basis of their system, and constitutes one of its greatest faults. It has since been ascertained that the metalloids in question, as well as some others, by uniting with hydrogen, form acids as energetic and as well characterized in every respect as the oxy-acids; for example, chloride of hydrogen, fluoride of hydrogen, &c. These are called hydracids. Instead of being written out in full, as they have just been given, the names of these compounds are formed by fusing together those of their constituents, as chlorhydric acid, fluorhydric acid,

&c. The synonymous names, as hydrochloric and hydrofluoric acids, are still often used, but are not in accordance with the general principle that the name of a compound must commence with that of its electro-negative component; their inaccuracy was pointed out some years since simultaneously by Thénard and the late Dr. Hare of Philadelphia. The hydracids are capable of uniting directly with basic oxides or with metals, with separation of hydrogen in either case; in the first instance the hydrogen unites with the oxygen of the metallic oxide to form water, in the latter it is evolved as gas. The compounds thus formed were at first thought to contain oxygen, the hydracids being supposed to be oxygenated, and were admitted as salts without question; indeed one of them, common sea salt, is that from which the very idea of a salt was originally derived. An attempt has since been made to refer them to the oxygen class by supposing that they constitute when in solution, not simple binaries, but compounds of the original undivided hydracid with an oxide. Thus the compound of chlorine and sodium (common salt) was at one time often called chlorhydrate (or hydro-chlorate) of soda; it being claimed that the elements of an equivalent of water had united with its constituents to form chlorhydric acid and oxide of sodium (soda). From this (conventionally admitted) property of chlorine, and the metalloids allied to it, to form salts by direct combination with metals, they have been termed halogens (salt producers; Gr. $\delta\lambda\varsigma$, [sea] salt, and $\gammaεννῶ$), and their salts have been called haloid (from $\delta\lambda\varsigma$ and $\epsilonἶδος$, in the likeness of), to distinguish them from the oxygen salts.—The names of ternary compounds or salts, in the original acception of the term, are formed by combining the names of the acid and base of which they are composed, the name of the acid or electro-negative component supplying the generic, the base or electro-positive compound the specific name. If the name of the acid terminates in *ic*, this termination is changed into *ate*; if in *ous*, into *ite*; and to the words thus formed the name of the base is added. For example, sulphuric acid and oxide of lead form sulphate of the oxide of lead; sulphurous acid forms a sulphite of the same oxide; while hyposulphurous acid produces a hyposulphite, and hyposulphuric acid a hyposulphate. In like manner the compounds of nitric acid are nitrates, and those of nitrous acid nitrites of the bases with which they may be combined. When a salt contains as its base the oxide of a metal which forms but one well defined base with oxygen, its name is usually shortened by leaving out the words "of the oxide," which are always understood. Thus, it is customary to say sulphate of lead, instead of sulphate of the oxide of lead; nitrate of potassa, instead of nitrate of the oxide of potassium. In case more than one basic oxide of the same element is capable of combining with acids, the distinguishing prefix of

each is retained in the name of its salts; as sulphate of protoxide of iron, and sulphate of sesquioxide of iron. These salts are also often called respectively protosulphate and persulphate of iron, the prefixes being understood to refer to the degrees of oxidation of the metal. As the number of salifiable oxides of any element is rarely if ever greater than two, it was proposed by Berzelius to distinguish them in some cases, like the acids, by the terminations *ous* and *ic*. The two oxides of iron he called ferrous oxide and ferric oxide respectively, and the salts just mentioned ferrous and ferric sulphate; and so with the oxides of various other metals. These changes are very convenient in certain cases, and for these they have been extensively adopted. In this instance, however, as in many others, the ill-advised attempts of some authors to generalize a system which is of convenient application only in a few special cases, have tended to create confusion. As a rule, the nomenclature of each special branch of chemistry will exhibit its own peculiar tendency, and all that the writers of text books can do is to choose that portion of each branch which is the best known or the most convenient. The history of the science has already proved again and again that all attempts to force an arbitrary nomenclature into general use must fail. Witness for example several of the attempts of Berzelius, the efforts of L. Gmelin, and of many others.—It often happens that an acid can combine with the same base in several different proportions. Of the salts thus formed, one is called neutral, or more properly normal, since the definition now depends upon some one constant relation in which the oxygen of the acid stands to that of the base for the salts of each individual acid, and not at all upon any lack of acidity or alkalinity; those containing more base than this are termed basic, and those containing less, acid salts, as basic chromate of lead, neutral chromate of lead, &c. The term neutral or normal is not usually expressed, being understood to belong to any salt which is characterized neither as basic nor as acid. Acid salts are often called collectively super-salts, and basic salts sub-salts; and when but one acid or basic salt of any oxide exists, this may also be designated as the super- or sub-salt of that oxide, as the case may be; but these terms have often been used erroneously, as with the normal carbonates of soda and of potassa, which are frequently called sub-carbonates. When several acid salts of any one base occur, they are distinguished from each other by the Latin prefixes *bi*, *ter*, &c., which are attached to the name of the acid; thus, monochromate (or simply chromate), bichromate, and terchromate of potassa. When several basic or sub-salts occur, they are usually distinguished by prefixing the terms bibasic, sesquibasic, terbasic, &c., to the name of the salt. Thus, 5 acetates of lead are known: monobasic (or normal) acetate of lead, symbol

$\text{PbO } \bar{A}$; bibasic do., $(\text{PbO})_2 \bar{A}$; sesquibasic do., $(\text{PbO})_3 \bar{A}$; terbasic do., $(\text{PbO})_4 \bar{A}$; sexbasic do., $(\text{PbO})_6 \bar{A}$. It has also been proposed to denote the amount of base in a sub-salt by prefixing to its name the Greek numerals *dis* (twice), *tris* (thrice), *tetrakis* (4 times), &c., in contradistinction to the Latin ones used for acid salts. Thus, instead of bibasic acetate of lead, the term diacetate of lead would be used; instead of terbasic acetate of lead, trisacetate of lead, and so on. These terms have, however, never been generally adopted, though still frequently used and well understood. Many oxides act as bases under certain circumstances, as acids under others; they may have therefore two different names. Thus the oxide of aluminum when acting as a base is called sesquioxide of aluminum (or alumina); but when playing the part of an acid, it is termed aluminic acid. Water (protoxide of hydrogen) is another oxide which is either acid or basic according to circumstances; when it plays the part of an acid its salts are termed hydrates, as hydrate of potassa, &c. The principles of the nomenclature have not been carried out, however, in regard to the compounds in which it acts as a base. Several of our most common acids are such compounds; but instead of saying sulphate of water, nitrate of water, &c., they are termed hydrated sulphuric acid, hydrated nitric acid, &c.; or, oftener, simply sulphuric acid or nitric acid, terms which ought, strictly speaking, to be applied only to the anhydrous compounds. In like manner certain salts, which contain two equivalents of acid united with one equivalent of a metallic base and one equivalent of water, which ought to be regarded as double salts, are named as if they were bisalts, containing two equivalents of acid to only one of base, the water being left out of account. Thus the compound of one equivalent of water, one equivalent of potassa, and two equivalents of sulphuric acid, is commonly called bisulphate of potassa.—The names of some of the ternary sulphur compounds (sulphur salts) are formed in a similar manner to those of the corresponding compounds of oxygen; thus the compound of sulphide of sodium and sulphantimonic acid is called sulphantimoniate of the sulphide of sodium. Like the names of the oxygen salts, these are usually abbreviated. In the instance cited, the salt is commonly termed sulphantimoniate of sodium, it being understood that the latter element is united with sulphur. But this system is limited to only a few of the sulphur acids; the terms sulpharseniate, sulphantimoniate, and sulphomolybdate are well understood; but the sulphophosphates, for example, of Berzelius (MS , PS_2) have never been generally so called; indeed, A. Wurtz has not hesitated to appropriate the name for an acid discovered by himself in 1847, the formula of which is $\text{P}(\text{O}_2\text{S}_2)_3$, which unites with oxygen bases to form salts of the composition $8\text{MO P}(\text{O}_2\text{S}_2)_3$, and chemists have not called in question the pro-

priety of this course. Since the Guyton-Lavoisieran nomenclature was made for the compounds of oxygen, it seems but fair that these should continue to take precedence, as they always have done.—The names of the ternary compounds of some of the other metalloids may also be formed like those of the oxygen compounds, but such a nomenclature has not been generally applied to them. They are usually regarded as double salts, and, as with the quaternary oxygen compounds, the names of both the constituent salts are expressed. Thus, as a compound of sulphate of alumina and sulphate of potassa would be called a double sulphate of these bases, or more shortly sulphate of alumina and potassa, so a compound of bichloride of platinum and chloride of potassium is called double chloride of platinum and potassium, or simply chloride of platinum and potassium. Of late, however, it is becoming customary to speak of this salt as chloro-platinate of potassium; in like manner the corresponding gold and mercury compounds are called respectively chlor-aurate and chloro-mercurate of potassium.—So long as the attention of chemists was principally directed to the consideration of inorganic compounds, the system of nomenclature just described, in spite of its numerous faults and inconsistencies, was found to be sufficiently expansive to meet all requirements. It has however failed to furnish suitable names for many new classes of compounds which have recently been discovered. This is especially true of the great variety of organic substances, with the study of which chemists of the present day are chiefly occupied. But the radical fault of the system is its intimate connection with the so called dualistic theory as just developed, which supposes all compounds to be capable of division into two prime factors, as salts into acids and bases, and these into still simpler antagonistic components; a view which is at present by no means so generally admitted as it was formerly. Owing to this cause, while every one admits the great merit of the system, while its intrinsic excellence and the valuable services which it has rendered are conceded, a feeling adverse to it is nevertheless entertained by some chemists. It is admitted, for instance, that it can hardly fail to warp the judgment and prejudice the mind of students; for since in this system theory assigns a name, so also the name expresses the theory, leading the learner to forget that the latter is a mere supposition, and to regard it as well ascertained truth. On this account, as well as from a fear of the changes which every new hypothesis may introduce, some have urged that a purely arbitrary nomenclature should be devised. Fortunately as the science would be on many accounts if theory were utterly excluded from its nomenclature, it must nevertheless be remembered that the realization of this proposition would be a mere retrogression to the confusion of names of the alchemists. The alternative seems to lie between burdening the memory with a count-

less multitude of badly defined names and synonyms, and allowing theory to hold a somewhat undue prominence. It need not be added how much all experience favors the latter course. The system of nomenclature in question has moreover been found to be incapable of expressing innumerable decompositions and changes which occur among complex substances. But this difficulty has been in a measure obviated by the introduction of certain written abbreviations (see *SYMBOLS, CHEMICAL*) and formulas, which exhibit at once to the eye the composition of bodies and the alterations to which they are subject. Indeed, since the adoption of these symbols, the name of a substance is of comparatively little scientific importance. The introduction of many names synonymous with those now used has thus been unquestionably prevented, and numerous other alterations obviated. This is a most fortunate result, since no material change in the spoken nomenclature can be made without great inconvenience. Indeed, the importance of maintaining a fixed spoken nomenclature or language, in which chemists may hold communion with the world at large, can hardly be overrated, for by means of it scientific information is far more readily imparted to technologists, and the "applications" of chemical science materially promoted. To the professed scientific chemist it might be of comparatively little moment if the nomenclature of Guyton de Morveau were suddenly replaced by some other system; but who can estimate the disturbance which such a course would create among all the dependent or allied sciences and arts? It has been well said that changes in nomenclature are like those in language; in mature age it is difficult to supplant one's native tongue, or to give up the text books studied in youth. For a similar reason many chemists, otherwise unprejudiced, believe that it is of importance to retain the dualistic theory itself as long as possible, conceiving that its practical advantages far more than counterbalance its theoretical failings.—It would be impossible to notice in this place the different theories of the constitution of bodies which have been advanced at one time or another, or to enumerate the various systems of nomenclature which have been devised, especially for organic compounds. Since no one of them has been generally adopted, it will be necessary to call attention to a few prominent features only, concerning which the greater number of chemists are in accord. Since, from their complexity, it would be impossible to name organic compounds from the names of their ultimate components, they are named much as if they were elements, somewhat at random, the terms applied to them being often derived from the names of the plants or animals, or organs, from which they were first obtained. This is especially true of the organic acids and of a numerous class of compounds termed compound radicals, which, though they contain several elements, never-

theless comport themselves like simple substances toward the elements. For example, cyanogen, a compound of two equivalents of carbon and one equivalent of nitrogen, exhibits properties closely analogous to those of the element chlorine. In general the term radical is applied to any substance which by uniting with an element can give rise to an acid or a base. Many of the more simple compounds formed by the union of compound radicals with elements or with other compound radicals are classed with the chlorine salts; as cyanide of potassium, chloride of ethyl, &c., the radical ethyl being composed of 4 equivalents of carbon and 5 of hydrogen. Some of the compound radicals acting as metals can unite with oxygen to form bases or acids, which, when combined with each other, produce salts which are completely analogous to the oxygen salts of inorganic chemistry. Thus the radicals ethyl and benzoyl, after combination with oxygen, are respectively a base and an acid, which by uniting form benzoate of the oxide of ethyl (benzoate of ethyl). In general terms it may be said that the nomenclature of organic acids, bases, and salts is similar to that of analogous inorganic substances. It is among the radicals themselves, and the numerous neutral or indifferent complex bodies of organic chemistry, that the system is at fault. Organic compounds are usually divided into natural families or groups, the generic names of which are furnished in each case by the name of some one substance which happens to be familiarly known, and to which each member of the group is in some way allied. Thus the term alcohol is applied to a large class of bodies analogous to common alcohol, each separate member of the class being designated by prefixing its specific name; as, methyl alcohol (wood spirit), ethyl alcohol (common alcohol), &c. In like manner ether is the generic name of a large class of bodies of which common ether is the type. So with the terms aldehyde, mercaptan, &c.; these barbarous names are purposely cited as evidence of how important it is to exercise care in naming even what appear to be the most insignificant substances, for at any moment they may stand forth, like those just mentioned, as the types of great families. In compounds produced by substitution (see *CHEMISTRY*), that is, in those cases where one or more of the equivalents of an element are replaced in a compound by equivalents of other elements or of compound radicals, names are formed by prefixing to the name of the original compound that of the element or elements which have been newly introduced. The prefixes *di*, *ter*, &c., or *di*, *tris*, *tetra*, &c., if the replacing substance possess basic properties, are used to denote those cases where two or more equivalents of any one element are substituted. Thus, acetic acid, in which one equivalent of hydrogen has been replaced by an equivalent of chlorine, is called chloracetic acid (or monochloracetic

acid), when 3 equivalents of hydrogen are thus replaced, it is called trichloroacetic acid. When one equivalent of hydrogen in ammonia is replaced by ethyl, the resulting compound is called ethyl ammonia, or shortly, ethylamine; when two equivalents of hydrogen are thus replaced, it becomes diethyl-ammonia (diethylamine), and so on. But each of the 3 equivalents of hydrogen in ammonia may be replaced by separate radicals, as in ethyl-methyl-amyl-ammonia. In similar cases exceedingly complicated names are often unavoidable; but such are rarely expressed without their written formulas.—Two or three common prefixes, beside those already mentioned, occur. Thus, *pyro* (abbreviated by Guyton de Morveau from the term empyreumatic, much used by the alchemists) is a distinguishing appellation of many acids obtained by means of dry distillation, as pyrogallic acid, &c. *Para* (Gr. *para*, near to) was proposed by Berzelius to indicate a strong resemblance between two compounds, as tartaric and paratartaric acids, which, though very much alike, must nevertheless be regarded as distinct substances. *Meta* (Gr. *meta*, signifying change) is also used in a somewhat similar manner. Thus, when aldehyde is kept for a long time in a closed tube, it gradually changes into two compounds, both isomeric with the original substance; one of these is called metaldehyde, and the other paraldehyde.—Many chemists have sought to apply names terminating alike to all the members of a given class. Although it is not easy to carry out this principle in detail, it has nevertheless been successfully applied to the names of several classes of compound radicals which terminate in *yl*, or simply *y*, as ethyl, methyl, &c. The names of the alkaloids also, and in general of bases which are not radicals like ethyl, terminate in *ine*, as strychnine, morphine, and the like. Special instances like these and exceptions in any number might be cited, but are hardly of sufficient general interest to be mentioned in this place. While chemical classification and the details of chemical nomenclature, like those of any other language, must of necessity change in accordance with the new facts and theories which are continually brought forward as the science advances; while the nomenclature will doubtless sooner or later free itself from the trammels which the theory of Lavoisier has imposed upon it; its most important features will nevertheless be retained; a rational method of forming the names of compounds from those of their constituents, and a uniform system of terminations, being advantages which the cultivators of chemical science can never consent to lose.

NOMINALISM, REALISM, AND CONCEPTUALISM, three prominent and conflicting doctrines of the scholastic philosophy. According to the first, all expressions for so called universal ideas, for genera, species, and the abstract qualities of things, are mere names, articulations, *status vocis*, having no corresponding object, and designating no reality. They do

not stand for any conception of the mind, still less for any entity out of the mind, but are merely verbal signs. Thus nominalism claimed that there is no such thing as an abstract animal or as a tree in general, but only individual animals and trees; there are in man no faculties or virtues in general, but only particular faculties and virtues; there is no beauty and no morality in general, but only beautiful objects and moral acts; there is nothing in the universe of matter or mind but separate individualities. We cannot even form a pure conception of universals, but can only think of the words which designate them. Realism, on the contrary, affirmed that universals, genera, and species are not mere figments of language, but that they have an objective existence, are incorporeal realities, are the essences or types of things, not to be confounded with the things themselves, and that to generic as well as singular terms there is a concrete corresponding entity. Conceptualism was proposed as an intermediate doctrine between these extremes. It gave to universals a logical or psychological existence as mental conceptions. The germ of this scholastic controversy is found in the ancient opposition of Platonism and Aristotelianism concerning the nature of ideas. Plato maintained *universalia ante rem*, that the world existed as a divine idea or plan before being realized, and that it still has an ideal existence in the thought of God, which it will for ever retain; that this idea or plan is disintegrated into many more or less general ideas, of classes, species, and individuals, all having an eternal reality in the divine thought; and that these ideas constitute the substance of all particular things. This Platonic theory of ideas lies at the foundation of realism. Aristotle maintained *universalia in re* or *post rem*, that particulars are the only real substances, and that general ideas are abstractions of the human reason, derived from the objects presented to its observation. This view gave rise both to nominalism and conceptualism. The discussion was formally proposed by Porphyry, in a sentence preserved by Boëthius. "I will not inquire," he says, "whether genera and species really exist, or consist only in mere intellections, whether they are corporeal or incorporeal, and whether they are separable from particular objects or coexist in them." Roscelinus, a canon of Compiègne in the 11th century, was the first to give a distinct and complete development to nominalism, stating that universals have no real existence, but are mere names by which the kind of individuals is expressed. Applying the doctrine to theology, he was accused of tritheism, since by denying the validity of abstract or general ideas he could represent the Trinity as only a nominal and unreal unity. He was therefore condemned by the synod of Soissons (1092), and obliged to retract his assertions, and nominalism from that time fell under the suspicion of the church. His chief opponent was Anselm, whose realism was of an undecided and incomplete character.

William of Champeaux was the founder of scholastic realism, maintaining that universals are the only real entities, that the germs exist essentially in all individuals, which differ from each other only in the variety of their accidents. Thus realism verged toward pantheism, as nominalism inclined to scepticism. Roscelinus favored nominalism by regarding universals as only combinations of individuals. Abelard sought to reconcile the opposing parties by advancing the doctrine of conceptualism. To attain the truth, three things, he says, must be remarked: the mind which conceives; the external individuals which are perceived; and the analogies, resemblances, and common qualities which the mind discovers in them, and which it reunites in distinct groups, of which it forms so many distinct conceptions. Thought and being are thus identified, since the mind can abstract from objects only what is essentially contained in them. He noticed the important part played by language in the formation of general ideas, without the aid of which nearly every operation of the reason would be impossible. Thus we could scarcely operate on numbers if the memory were obliged to retain separately every unity, if there were no such generalizations as scores and hundreds; still less could we deal with concrete individualities, in the attributes of which the idea of quality is added to that of quantity. Yet conceptualism rather avoided than solved the problem. It did not inquire whether beyond the understanding which conceives general ideas, beyond the individuals in which resemblances are found, there are laws, principles, a plan, which is the common source of the resemblances and the sovereign type of the ideas. He did not grasp the view proposed by modern critics of scholasticism, that universals are more than either human conceptions or concrete substances, that they are the ideas of God, or in other words the laws of which individuals are the expressions, and that individuality is but a particular application of the law. "The moderation of conceptualism," says Cousin, "secured its triumph. A few nominalists of no renown succeeded; realism was more honorably represented; but the sceptre of the schools was swayed by the new doctrine." John of Salisbury wrote "that there had been more time consumed in the discussion than the Cæsars had employed in making themselves masters of the world; that the riches of Cræsus were inferior to the treasures that had been exhausted upon it; and that the contending parties, after having spent their whole lives on this single point, had neither been so happy as to determine it to their satisfaction, nor to find in the labyrinths of science where they had been groping any discovery that was worth the pains they had taken." The Thomists and the Scotists, though disagreeing with each other, united in assailing nominalism, which had become nearly extinct, when it was revived by William of Occam, *princeps nominalium*, an English Franciscan, in the 14th century. He declared

that in the mind of God there is an idea corresponding to every thing created or possible; that only individuals can be created, and that they alone imply the existence of the idea which is their type and plan; and that there can be no similar ideas of genera and species. He thus transferred reality from the ideas of universals to those of individuals, and reduced the former to abstract notions. His theory includes the principal doctrine of conceptualism. The controversy now became so violent that the doctors, according to Vives, often came to blows, not only with their fists but with clubs and swords; and Occam died in exile after having identified nominalism with the movements against the ecclesiastical theology and the policy of the papacy. Among his followers were Holcot, Rimini, Buridan, Pierre d'Ailly, Heinrich von Hessen, Nikolaus Oresmius, and Gabriel Biel; yet political influence contrived the proscription of his doctrine by Louis XI. (1478), the masters being forbidden to teach it, and the books which favored it being ordered to be given up to the president of the parliament or chained in the public libraries. The proscription was removed in 1481, and the nominalists flourished in France and Germany, while realism was protected and encouraged in Italy by Pope John XXIII. Among the defenders of realism in the 14th century were Henry of Ghent, Walter Burleigh, Thomas of Strasbourg, Marsile of Inghen, and Thomas of Bradwardine. Nominalism contributed to introduce a freer spirit into speculation, and with the revival of letters and the Protestant reformation to overthrow scholasticism. The later nominalist theory of ideas has generally prevailed in modern philosophy, which however has rarely adopted the watchwords of mediæval speculation. The modern German systems of idealism, which identify being and thought, are the principal examples of a realistic tendency. —See Salaberti, *Philosophia Nominalium Vindicata* (Paris, 1851); Baumgarten-Crusius, *De Vero Scholasticorum Realium et Nominalium Discrimine* (1821); Erner, *Ueber Nominalismus und Realismus* (1842); and Cousin, *Fragments de philosophie scholastique*.

NONCONFORMISTS, a general name given to the Protestant dissenters from the church of England. They existed as early as the English church itself, and during the reign of Elizabeth were made the subjects of persecution, which did not however have the effect of shaking their allegiance to that queen. "The nonconformists," says Macaulay, "rigorously as she treated them, have, as a body, always venerated her memory." Several acts were passed against them during her reign, one of which was the act of uniformity (1558), enforcing severe penalties against any one conducting public service in any other manner than that prescribed by the "Book of Common Prayer." These enactments were neither removed nor modified during the reign of James I., and the

accession of Charles only rendered the condition of the dissenting bodies more intolerable. When, however, the protectorate was established, the nonconformists enjoyed the right of worship without molestation, and Episcopacy in its turn was proscribed. The restoration witnessed the reestablishment of the old church polity, and the revival of the penal laws against the dissenters. A new act of uniformity was passed in 1662, restoring all the ancient forms and ceremonies of the established church, and requiring that every beneficed minister, every fellow of a college, and even every schoolmaster, should declare his assent to all and every thing contained in the "Book of Common Prayer," and that no one should hold any preferment without episcopal ordination. For their unwillingness to conform to the requirements of this act, 2,000 clergymen were obliged to give up their livings, and it was at this time that the title of nonconformists came into general use. Among the oppressive laws passed against them during the reign of Charles II. were the conventicle act, inflicting severe punishments upon all who attended religious meetings not according to the practice of the church of England; the corporation act, aimed at the Presbyterians, whose strength lay in the small corporate towns; and an act requiring every one in holy orders to take an oath denying the right to take up arms against the government on any pretense whatsoever, on pain of being deprived of the privilege of teaching in schools, or of coming within 5 miles of any city, corporate town, or borough sending members to parliament. The "Declaration of Indulgence" of James II. afforded a temporary relief to the nonconformists; but it was not until the reign of William and Mary that they enjoyed any real toleration, and even from this those who denied the Trinity were excepted. After this, with occasional exceptions, milder counsels prevailed; the penal laws were one after the other repealed, and those that remained on the statute books were liberally interpreted, so that now the nonconformists are in the full enjoyment of political and religious liberty.

NONJURORS, that portion of the English clergy who, after the expulsion of James II. and the coronation of William and Mary, refused to take the oath of allegiance to their new sovereigns. Many of these had strenuously opposed the course of King James, but, as they had been prominent champions of the doctrine of passive obedience, they could not conscientiously acknowledge the authority of the new government. In consequence, 8 bishops, including Sancroft, the primate, and about 400 of the clergy, were deprived of their sees and benefices. In the house of lords an amendment to the act requiring the oath to be taken was moved and passed, providing that the clergy should be excused from taking it; but the commons steadily refused to make any such distinction in their favor, although 6

months more time was allowed to them than to laymen. In Scotland many of the extreme Presbyterians refused to take the oath, considering that their nation was bound to be governed for all time according to the "Solemn League and Covenant." These men were subsequently called non-hearers, and existed as late as the reign of George III. The subsequent lives of many of the English nonjurors were any thing but creditable, and the popular opinion in regard to them may be ascertained from the now almost forgotten play of Cibber, entitled "The Nonjuror," founded on the *Tartuffe* of Molière. Some of them became identified with the Jacobites.

NONPAREIL, the painted bunting or finch (*S. ciris*, Bonap.). See FINCH, vol. vii. p. 505.

NONSUIT (L. Fr. *nonsue*, *non suist*, modern Fr. *non suit*, Lat. *non sequitur*, he does not pursue), in law, a judgment given against a plaintiff in default of evidence, or for neglect to proceed with a cause after it has been put at issue. A plaintiff may find after commencing his action that he cannot maintain it for want of evidence. In order therefore to prevent a verdict and judgment which will be not only probably unfavorable to him, but also a bar to further process upon the same cause of action, he may abandon his suit and defer its complete prosecution until he is prepared with fuller testimony; in other words, he becomes nonsuit. *Non sequitur clamorem suum*, says Blackstone; or in the similar language of the entry formerly made in England on the court record: *Non prosecutus est breve suum*; that is to say, the plaintiff has not prosecuted or followed up his complaint, he does not support his claim, or he does not keep up his clamor. The plaintiff may become nonsuit at any time before verdict, unless an exercise of his right will wrong the defendant. If he fails to appear for the trial of his cause, the crier usually in open court calls upon him to come in and prosecute it; and if he does not, he is noted upon the docket as nonsuit, the action is at an end, and the defendant recovers his costs against him. If the plaintiff has once appeared, it seems to be the English rule, and that of many of the United States, that he cannot be nonsuited except by his own consent, provided he has offered pertinent, even though it was the slightest, evidence in support of his claims. In some of the states, however, where this rule is maintained, the presiding judge recommends a nonsuit subject to the opinion of the full court. But in New York and other states, it is held to be within the power, and even duty, of the court to nonsuit the plaintiff, if in its opinion the testimony which he has offered will not authorize the jury to find a verdict for him, or if the court would set aside such a verdict as being contrary to the evidence. Yet in such a case of involuntary nonsuit the plaintiff may, upon a case made or upon a bill of exceptions, move to have the nonsuit set aside.—A nonsuit is a mere default. It does not, like

judgment following upon a verdict, change the face of the matter in controversy. It leaves the parties in the same position toward each other as if no action had been brought. In submitting to it, the plaintiff does not admit that he has no cause of action; and, subject only to the probable order of court that further proceedings be stayed until the costs of the former suit are paid, the plaintiff is entitled to institute a new action at his pleasure.

NOOTKA SOUND, an inlet on the W. coast of Vancouver island, British North America, in lat. $49^{\circ} 35' N.$, long. $126^{\circ} 35' W.$ It extends 10 m. in a N. N. E. direction, and forms a number of smaller bays and coves. It communicates with the Pacific by two entrances, separated by a wooded island, and the greatest breadth of water is not more than 500 yards. The shores are rocky, and the anchorage good.

NORD, the northernmost department of France, formed chiefly from the old province of Flanders, bounded N. by the North sea, N. E. and E. by Belgium, S. by the departments of Ardennes and Aisne, and S. W. by Somme and Pas-de-Calais; area, 2,198 sq. m.; pop. in 1856, 1,212,358. The coast line is formed by a ridge of sand hillocks, and has two harbors, Dunkirk and Gravelines. The principal rivers are the Sambre, Scheldt, Scarpe, Lys, and Yser, which have been rendered navigable, and are connected with one another by 25 canals. The surface is flat, except in the S., where there are some low detached hills. The greater part of the soil is a rich alluvium, and when properly drained yields very rich crops. All the ordinary cereals are raised, beside hemp, flax, tobacco, hops, dye plants, roots, &c. Coal is found in several places. Linen, woollen goods, and cottons are manufactured; and there are iron works, foundries, and glass works. The climate is damp, and not considered healthy. Capital, Lille.

NORD, CÔTES DU. See **CÔTES DU NORD.**

NÖRDLINGEN, a fortified town of Bavaria, formerly an imperial free city, situated in the circle of Swabia and Neuburg, 50 m. S. W. by railway from Nuremberg; pop. 6,500. It is surrounded by walls with towers at intervals, contains a handsome Gothic church of the 16th century, with a tower 268 feet high and many fine paintings, an orphan asylum, and manufactories of linens, woollens, carpets, and leather. In 1684 a Swedish army under Gen. Horn and Bernard of Weimar was defeated here by the imperialists, commanded by Ferdinand, the emperor's son. The battle, which was one of the most important in the 30 years' war, lasted 8 hours. The Swedes lost 20,000 men, and Gen. Horn was taken prisoner. A second battle was fought in the same war near Nördlingen, Aug. 3, 1645. In 1647 the town was bombarded and partly burned by the Bavarians. Battles between the French and Austrians were also fought there in 1796 and 1800.

NORE. See **THAMES.**

NORFOLK. I. An E. co. of Mass., having Massachusetts bay on the N. E., and Rhode

Island on the S. W.; area estimated at 450 sq. m.; pop. in 1860, 108,065. It is watered by the Charles, Neponset, and other rivers. The surface is rough, and in some places hilly, and the soil strong and rocky and highly cultivated. Granite of an excellent quality is quarried at Quincy. The agricultural productions in 1855 were 150,465 bushels of Indian corn, 15,872 of rye, 6,935 of barley, 12,732 of oats, 281,586 of potatoes, 816,354 lbs. of butter, and 42,621 tons of hay, beside a great quantity of vegetables raised for the markets of Boston and surrounding towns. There were 29 cotton, 5 woollen, 3 carpet, and 16 paper mills, 6 rolling, slitting, and nail machines, 86 forges, and 10 tanneries, beside many other manufacturing establishments. Boots and shoes to the value of \$4,990,700 were manufactured. In 1858 there were 126 churches and 5 newspaper offices. The Old Colony and Fall River, the Boston and Providence, and the Norfolk county railroads traverse the county. Capital, Dedham. II. A S. E. co. of Va., bordered S. by N. C., having the mouth of James river or Hampton roads on the N., and Chesapeake bay on the N. E. corner, and drained by Elizabeth and North rivers; area, about 500 sq. m.; pop. in 1850, 83,086, of whom 10,400 were slaves. It has a level surface, and comprises a large portion of the Dismal swamp. The productions in 1850 were 807,245 bushels of Indian corn, 21,803 of sweet potatoes, and 2,864 lbs. of wool. There were 10 grist mills, 5 saw mills, 2 iron foundries, 3 ship yards, 13 newspaper offices, 42 churches, and 1,926 public school pupils. The county is intersected by the Seaboard and Roanoke railroad, and by the Dismal swamp canal. Capital, Portsmouth.

NORFOLK, a S. W. co. of Canada West, bordering on Lake Erie, drained by Big, Otter, and other creeks; area, 600 sq. m.; pop. in 1851, 21,281. It has an undulating surface and fertile soil; and in 1851 there were 97 saw mills, 9 fulling mills, 2 woollen factories, and 6 tanneries. The county is intersected by the Lake Erie and Woodstock railroad. Capital, Simcoe.

NORFOLK, a city and port of entry of Norfolk co., Va., on the N. bank of Elizabeth river, 8 m. from Hampton roads, 32 m. from the ocean, and 106 m. by land and 160 by water S. E. from Richmond; lat $36^{\circ} 50' 50'' N.$, long. $76^{\circ} 18' 47'' W.$; pop. in 1854, 16,500; in 1860, 14,605, of whom 3,280 were slaves. Its situation is low. The streets are generally wide, but irregularly laid out, and the houses well built of brick and stone. Among the principal buildings are the city hall, having a granite front and a cupola 110 feet high, the Norfolk military academy, mechanics' hall, and Ashland hall. There is a beautiful cemetery, handsomely laid out and adorned with cypress trees. The city contains a court house, gaol, custom house, 3 banks, and 14 churches. The new custom house and the buildings of the farmers' and exchange banks are elegant structures. It has a fine harb easily accessible and safe, ad-

mitting the largest vessels. The entrance is defended by Forts Calhoun and Monroe. In the vicinity, at Gosport, is a U. S. navy yard with a marine hospital. The yard contains a dry dock constructed of granite at a cost of \$974,586. The foreign commerce of Norfolk exceeds that of any other place in the state. The entrances for the year ending June 30, 1859, were 121 vessels, tonnage 62,159; clearances, 128 vessels, tonnage 25,273; tonnage of the district, which includes Portsmouth on the opposite side of the river, 25,728. The supplying the northern cities with early fruits and vegetables has become an important trade, and is said to reach from \$250,000 to \$500,000 annually. The city was laid out in 1736, and was burned in 1776 by the British. It is now the second city in importance and population in the state. With New York and Philadelphia it communicates by regular lines of ocean steamers. The city was severely visited by the yellow fever in 1855, losing between 1,000 and 2,000 inhabitants directly and indirectly.

NORFOLK, a maritime co. of England, bounded N. and N. E. by the North sea, S. E. by Suffolk, W. by Cambridge, and N. W. by Lincoln and the Wash; area, 2,116 sq. m.; pop. in 1851, 442,714. The coast consists of cliffs, partly chalk, which the sea is gradually undermining, and several villages at different periods have been swept away. The surface is generally flat, except in the N., where it is undulating. The soil is light, and there is little woodland; but no county in the kingdom has made greater progress in agriculture. The principal rivers are the Great and Little Ouse, Nen, and Yare. The climate on the E. coast is dry throughout the year, and in winter and early spring cold penetrating winds prevail. The crop raised in greatest perfection in Norfolk is barley, most of which is made into malt and exported. Turnips are also raised in great abundance. The stock of sheep amounts to about 800,000 head; much poultry is raised for the London market. There are valuable fisheries of herrings and mackerel. Woollen manufactures, especially of worsteds, are largely carried on. Norfolk sends 12 members to the house of commons, 4 for the county, 2 for the city of Norwich, and 2 each for the boroughs of King's Lynn, Thetford, and Yarmouth.

NORFOLK, DUKE OF. See HOWARD, THOMAS.

NORFOLK ISLAND, a dependency of the British colony of New South Wales, in the S. Pacific ocean, 900 m. E. N. E. from Sydney, in lat. 29° 10' S., and long. 167° 58' E. It is the largest of a small cluster consisting of Norfolk, Nepean, and Philip islands, together with several islets, or rocks, called the Bird islands. It is about 5 m. long, with an average breadth of 2½ m.; area, about 9,000 acres. Its general elevation is 400 feet above the sea, except on the N. W. corner, where Mt. Pitt rises to the height of 1,050 feet. The surface is very uneven, and the coast high and precipitous. The small streams which occupy the ravines in win-

ter fall in cascades, 80 to 50 feet high, into the sea. The soil is fertile. The principal tree is the Norfolk island pine, which grows to a very great size, but the wood is of little use except for building purposes. Maple, ironwood, a small species of palm, a gigantic fern having fronds 11 feet in length, the lemon, guava, banana, yam, sweet potato, and arrowroot grow luxuriantly; and oranges, coffee, maize, and wheat may be raised. The climate is healthy and very agreeable. Horses, horned cattle, sheep, and other domestic animals have been introduced.—Norfolk island was discovered by Capt. Cook in 1774, and in 1787 was colonized by convicts and freemen from New South Wales; but it was abandoned in 1810, and all the buildings were destroyed. In 1825 it was made a penal establishment for the safe keeping of incorrigible offenders from among the convicts of New South Wales, for which, as there are only two spots where a landing can be effected, and there even with danger, it was thought peculiarly well adapted. At one time the number of prisoners was more than 2,000; large prisons and other buildings were erected, roads and various improvements were made, and a strong military guard was stationed at the place to keep order and prevent escape; notwithstanding which many convicts made their way to various South sea islands. After the colonists of New South Wales refused to permit any more convicts to be landed in that country, the establishment on Norfolk island became no longer necessary, and it was abandoned in 1856. The island was then given by the British government to the inhabitants of Pitcairn island, the descendants of the mutineers of the *Bounty*, 194 in number, who took possession in that year; and though some of these have since returned to Pitcairn, the population by last accounts amounted to 202.

NORICUM, a province of the Roman empire, in S. E. Germany, bounded N. by the Danube, E. by Mt. Cetus (now Kahlenberg), which separated it from Pannonia, S. by the Savus (Save) and Mt. Oera (Terjoul), and W. by the *Ænus* or *Enus* (Inn), which separated it from Vindelicia and Rætia. It thus comprised the whole of the modern province of Upper Austria, almost the whole of Lower Austria, Styria, and Carinthia, and parts of Carniola, Salzburg, and Bavaria. The principal rivers, beside those already mentioned, were the *Anisus* (Enns), *Murus* (Mur), *Dravus* (Drave), and *Juvavus* (Salza). The most important range of mountains was the *Norio Alps*, in the neighborhood of Salzburg, where excellent iron was mined. Noricum had also some gold mines. The chief towns were: *Noreia* or *Noreja* (Neumarkt in Styria), from which the name of the province was derived, the capital of the *Taurisci* or *Norici* before the Roman conquest, and the place where *Carbo* was routed by the *Cimbri* in 118 B. C.; *Juvavia* (Salzburg), a colony of *Hadrian*, on the *Juvavus*; *Lentia* (Linz), on the Danube; and

Lauriacum (Lorch), at the mouth of the Anisus. Noricum was conquered by the Romans toward the close of the reign of Augustus, and at a later period was divided into two provinces: Noricum Ripense, adjoining the Danube, and Noricum Mediterraneum, S. of the former.

NORMAL SCHOOLS (*Lat. norma*, a carpenter's square; hence, a rule or pattern), establishments for the education of teachers. The first institution worthy of the name of a normal school was organized in Stettin, Prussia, in 1785. Frederic the Great established a second in Berlin in 1748. Another was opened in Hanover in 1757, and others soon followed in various parts of Germany. Since the beginning of the present century, training schools for teachers have been rapidly multiplying in number, and advancing in the requisites for admission. The course of instruction is now generally extended to 3 or 4 years. In some of the German states the great majority of the teachers are graduates of the normal schools. The first seminary for teachers in France was established in 1810, and the first in Holland in 1816; and since that time they have been introduced into the other principal countries of Europe. There are now more than 90 normal schools in France, 40 in England, nearly 50 in Prussia, 18 in Switzerland, and a proportionate number in Saxony, Hanover, and Bavaria. Sardinia has lately established normal schools, including one for females, and inaugurated an excellent system of public instruction. Through the influence of the Rev. J. H. Hill, D.D., an American missionary for 30 years in Athens, a normal school for females has been established and is liberally supported by the government of Greece. A seminary for training female teachers has also been opened in Belgium.—To Prof. Denison Olmsted seems to belong the credit of first publicly advocating in America the necessity of a seminary for the training of teachers, in an oration delivered in New Haven, in 1816, "On the State of Education in Connecticut." In 1825 there appears to have been an almost simultaneous though unconnected movement for a normal school on the part of several prominent friends of education. Gov. De Witt Clinton, in his message to the legislature of New York in 1825, recommended a seminary for teachers, and repeated the recommendation the next year, with a plan contemplating the expenditure of \$200,000 for buildings alone. The same year James G. Carter of Massachusetts and the Rev. Thomas H. Gallaudet of Connecticut each called public attention to the necessity of normal schools, in a series of newspaper articles. The "United States Review," edited by Theophilus Parsons, strongly commended these essays and their object to popular favor; and in 1827 Prof. Ticknor gave an outline and an earnest advocacy of their plan in an article in the "North American Review." The same year a memorial on the subject was presented to the legislature of Massachusetts by J. G. Carter, and his

efforts were warmly seconded by Messrs. Emerson, Brooks, Woodbridge, Russell, Stowe, and others. Ten years later the American institute of instruction memorialized the legislature in behalf of a normal school and a board of education. On the recommendation of Gov. Everett the board of education was established. Its first secretary, Horace Mann, and all its members were the earnest advocates of normal schools. In 1838 Mr. Edmund Dwight offered the sum of \$10,000 for the purpose of establishing a normal school, on the condition that the state should appropriate an equal amount for the same purpose. Accordingly the first normal school in America, that now established at Framingham, was opened at Lexington, July 3, 1839. Two others were soon opened, and 4 are now supported by the state of Massachusetts, the whole number of persons ever connected with which is 5,271, and they have 2,525 alumni. New York established a normal school at Albany in May, 1844, and now appropriates \$12,000 annually for its support, which, with the income from the model school of over 100 pupils (\$2,600), makes this one of the most liberally sustained institutions of the kind in the country. The whole number of pupils who have been connected with the school is 3,408, of graduates 1,158, and of present pupils 268. The normal school in Toronto, C. W., was opened in 1847; it has fine buildings, is very liberally supported, and has a model school of 400 pupils; the whole number of those instructed in the normal department is 2,805, of whom 1,480 have received certificates. The Michigan normal school was legally established in 1849, and went into operation at Ypsilanti in 1853; it has had in all 1,200 members, and the present number of pupils is about 300. The commodious edifice, burned in 1859, is now rebuilding. Connecticut opened a normal school in New Britain in 1850, at first as an experiment for 5 years; its whole number of members is 1,744, of whom 138 have completed a 3 years' course, and it now has more than 500 pupils. A private institution for the training of teachers was opened at Providence, R. I., in 1852, which was adopted as a state normal school in 1854; it is now established at Bristol; whole number of pupils 506. The normal school of New Jersey was established at Trenton in Oct. 1855; it has superior buildings, is liberally supported, and has had 855 members and 146 graduates. The Illinois normal university went into operation in Feb. 1857, and has 150 members; the edifice, now nearly completed, promises to be the most magnificent building of the kind in the country. Another was opened in Charleston, S. C., in May, 1859; it is supported at an annual cost of \$10,000. In December of the same year one was legally "recognized" at Millersville, Penn., with accommodations for 300 members, and a hall that will seat 1,000 persons. Pennsylvania is now about to establish other schools of the same kind. During the winter of 1860 another was

established in Winona, Minnesota. Iowa connects a normal school with her state university. Wisconsin is now aiming to organize normal classes under the direction of the board of education in all her high schools, academies, and colleges, "to establish normal classes at two or more points of the state for a professional course for teachers already engaged in teaching, and to crown the whole by a central normal school." In 1860 Maine made appropriations to secure a normal department in certain existing academies. The attempt to engraft normal departments upon existing schools was long since made in some parts of Germany, but failed. In opposition to the counsel of Gov. Clinton the same experiment was tried for several years in New York. "This attempt," says Horace Mann, "was one of the most unfortunate movements ever made in this country in regard to education." The same error was made in Kentucky, but it was continued less than two years. Normal schools are also established in the cities of Boston, New York, Brooklyn, Newark, Philadelphia, St. Louis, and others; in Charlottetown, Prince Edward's island; in St. John's, New Brunswick; in Truro, Nova Scotia; and in Valparaiso, Chili; and one is soon to be opened at Madura, India. A private normal school is maintained at Lebanon, Ohio.—The "American Normal School Association" originated in a convention held in New York city, Aug. 30, 1855; and annual meetings have since been held in Springfield, Mass. (1856), Albany, N. Y. (1857), Norwich, Conn. (1858), Trenton, N. J. (1859), and in Buffalo, N. Y. (1860). In view of the recent origin and rapid increase of normal schools, an association for professional improvement was deemed essential by their instructors. Many fundamental points in reference to the distinctive character and specific aim of normal schools, the science of education, methods of instruction, terms of admission, curriculum of study, length of the course, prominence to be given to the theory and art of teaching, and the forms of general exercises, still demand investigation. The discussion of these and kindred questions, collating the results derived from the varied experience of those actually engaged in these schools, has already rendered a valuable service to the progress of normal school instruction. The proceedings of the convention held at Trenton in Aug. 1859, have been published in a volume containing plans and elevations of some of the principal normal school buildings in the country.

NORMANDY, an ancient province in the N. W. of France, extending along the English channel, from a point S. of the mouth of the Somme to the bay of Cancale, washed on the N. and W. by the sea, and bounded E. by Picardy and Isle-de-France, from which it was partly divided by the Bresle, the Epte, and the Eure, and S. by Perche, Maine, and Brittany, the upper Sarthe and the lower Oouesnon forming a part of the dividing line. The Gallic

hordes or nations who originally occupied this territory were subdued by the Romans, who included it in the province of *Lugdunensis Secunda*. It was comprised within the limits of Neustria under the domination of the Merovingian kings, and received the name of Normandy from the Northmen, who occupied it in the beginning of the 10th century. By the treaty of St.-Claire-sur-Epte, in 912, Charles the Simple gave his sanction to the conquests made by the Northmen, and Rollo, their chief, received the title of duke of Normandy. The new duchy soon became one of the most prosperous provinces of France, and its inhabitants bore a prominent part in many great events that marked the middle ages. Robert the Devil, or the Magnificent, the 5th successor of Rollo, is the hero of many legendary tales; and his son, William the Bastard, became in 1066 the conqueror of England. Several years before this adventurous knights from Normandy, William Bras de Fer, Robert Guiscard, and Roger, the sons of a simple baron, Tancred of Hauteville, had subdued the southern part of Italy and prepared for the establishment of the kingdom of the Two Sicilies. Many others bore a prominent part in the crusades. On the death of William the Conqueror, England and Normandy were separated, the latter falling to the lot of Robert Courteuse, while William Rufus seized upon the former. Henry I. Beauclerc ruled over both, but his daughter Matilda was only duchess of Normandy. Her son, Henry II., accomplished another reunion which lasted until the reign of King John. This prince, in his capacity of vassal of the French king, was summoned before the court of peers at Paris, on the charge of having murdered his nephew Arthur of Brittany, and sentenced to forfeit his duchy. This was forthwith seized upon by King Philip Augustus; but it was twice again held by the English, first under Edward III., and a second time, from 1417 to 1450, under Henry V. and Henry VI. The gallant Dunois, during the reign of Charles VII., finally rescued it from foreign control; and although the title of duke of Normandy was still occasionally used, the duchy thenceforth was an integral portion of the kingdom of France. Amid all these revolutions, the Normans had lost nothing of their energy and enterprise. While improving their lands at home and carrying on an active traffic with the neighboring countries, they had, as early as the 14th century, established trading posts on the coast of Africa, and at the beginning of the 15th taken possession of the Canary islands under Jean de Bethencourt. During the 16th century they extended their maritime expeditions, discovered the St. Lawrence, and attempted to colonize its banks. They founded Quebec in 1608, had settlements in Brazil in 1612, visited the southern islands of Malaysia in 1617, and settled in Guadeloupe in 1635. Subsequently Normandy contented itself with being one of the best cultivated and most industrious provinces in France; the cloths of Elbeuf and

Louviers, as well as the lace of Alençon, enjoy an excellent reputation. The province was sometimes assisted in its improvements by royal protection. It was indebted to Francis I. for the foundation of Havre, while Louis XVI. vigorously continued the great works that had been begun at Cherbourg by Louis XIV. The political part of Normandy in the revolution was important; it was here that the Girondists attempted to rise in arms against the convention; and it was from Caen that Charlotte Corday started for Paris to rid France of Marat. Normandy has contributed much to French literature. During the middle ages the Norman trouvères held a high rank as poets; and in modern times Malherbe, Corneille, Mézeray, Fontenelle, Vertot, Bernardin de St. Pierre, and Casimir Delavigne, beside Laplace and Vauquelin among scientific men, Poussin and Jouvenet among painters, and Boieldieu among musicians, were natives of the province. Normandy has lost nothing of its prosperity since its division in 1790 into the 5 departments of Orne, Seine-Inférieure, Calvados, Eure, and Manche. It was anciently styled the *pays de sapience*, on account of the shrewd and money-making character of its people.

NORMANS. See **NORTHMEN**.

NORRIS, EDWIN, an English ethnologist and philologist, born in Taunton, Oct. 24, 1795. From 1826 till 1836 he held a situation in the East India house. In 1836 he was elected assistant secretary to the royal Asiatic society, of which in 1856 he became principal secretary, and in 1847 was appointed by government translator to the foreign office. His reputation rests chiefly on articles which have appeared in the "Transactions" of the Asiatic society, among which the most noteworthy are the following: "On the Kapur-di-Giri Rock Inscription;" "On the Assyrian and Babylonian Weights;" and "On the Scythic Version of the Behistun Inscription." He is the editor of the "Ethnographical Library," begun in 1858, and has superintended the publication of several ethnological and philological works. He has been engaged with Sir H. L. Rawlinson in preparing for the press the series of Nineveh inscriptions, to be published under the authority of the trustees of the British museum. His last work is "The Ancient Cornish Drama, edited and translated" (Oxford, 1859).

NORRIS, JOHN, an English clergyman and author, born in Collingborne-Kingston, Wiltshire, in 1657, died in Bemerton in 1711. He was graduated at Exeter college, Oxford, in 1680, and shortly afterward, obtaining a fellowship of All Souls', devoted himself to philosophy, and became a disciple of the French Platonist, Father Malebranche. In 1682 he published his first work, "The Picture of Love Unveiled," a translation of the *Effigies Amoris* of Robert Waryng, and in the same year a translation from the Greek of "Hierocles upon the Golden Verses of Pythagoras." His first original work, entitled "An Idea of Happiness"

(1688), at once gave him a position in the ranks of the Platonic divines of the 17th century. The Rye house plot of 1683 led him to attack the whigs in a treatise entitled "A Murnival of Knaves, or Whiggism Displayed and Burlesqued out of Countenance." Soon afterward he published a Latin work against the theology of the Genevan divines, and followed it up in 1691 by a special treatise against the nonconformists, charging them with schism. In 1684 he took orders, and in the same year published his "Miscellanies" in prose and verse. At this time he began with Dr. Henry More, who had just won fame as a Platonic mystic, a correspondence in regard to some speculative difficulties, which lasted 3 years, and was published in 1688. In 1685, with Francis Digby, he produced a translation of Xenophon's *Cyropædia*, and in 1688 published "The Theory and Regulation of Love," in which he eloquently defended Platonic affection. In 1689 he became rector of Newton St. Loe, in Somersetshire, published the same year a treatise on "Reason and Religion," and in 1690 "Reflections upon the Conduct of Human Life," in a letter to Lady Masham. In 1692 he attacked the views of the Quakers, and was shortly after made rector of Bemerton near Salisbury, where he remained till his death. His duties being light, he wrote with still greater ardor; in 1693 he finished 4 volumes of "Practical Discourses," and in 1695 gave to the world his "Letters concerning the Love of God." The deist John Toland having written a treatise entitled "Christianity not Mysterious," Norris published in 1697 in answer, "An Account of Reason and Faith, in relation to the Mysteries of Christianity," in which he clearly distinguished the respective provinces of reason and faith. From the first he raised his voice against the philosophical theories of Locke, and in an appendix to his "Treatise of Christian Blessedness" he made some strictures on the "Essay on the Human Understanding." In 1701 he published in defence of idealism a work entitled "An Essay toward the Theory of the Ideal or Intelligible World," of which the second part appeared in 1704. By this work he is best known to philosophical students. In 1708 he published a treatise on the "Natural Immortality of the Soul," in answer to Dodwell; and this, with the exception of a few minor productions, may be regarded as his last work, his health giving way under his labors.

NORRISTOWN, a post borough and the capital of Montgomery co., Penn., situated on the N. bank of the Schuylkill river, 91 m. E. from Harrisburg and 16 m. N. W. from Philadelphia, with which it is connected by railroad; pop. in 1880 about 10,000. The streets are laid out at right angles and well paved, and the houses are built in a neat, substantial manner, of brick and native marble. The borough contains a handsome county gaol, a bank, a public library, 18 churches, 4 large public schools, several extensive cotton and woollen

factories, rolling mills, founderies, furnaces, machine shops, nail mills, oil mills, brick yards, and other manufactories, 1 German and 4 English newspaper offices, and 8 boarding schools, 2 of which have large and elegant edifices occupying high ground in the eastern part of the town. The new court house, finished in 1855, is built of the light gray native marble, and cost over \$200,000; it is one of the finest and best buildings of its class in the United States. The Schuylkill river is crossed by two substantial covered bridges, about 800 feet in length, leading into Bridgeport on the opposite bank. Water and gas are conveyed through the borough in pipes. Norristown is the E. terminus of the Chester valley railroad, which intersects the Columbia railroad at Downingtown, 22 m. distant. The improved navigation of the Schuylkill affords facilities for the trade of the town, which is active and increasing. The Reading railroad, on the opposite bank of the river, opens a ready communication to the coal mines of Schuylkill co.; and a railroad is in progress from Norristown to Allentown in Lehigh co. The borough was incorporated in 1812, and enlarged in 1853.

NORRLAND, WESTER. See **HEERLAND.**

NORSE (from the Danish *Norsk*, Norwegian), a word improperly applied by English writers to the Icelandic or ancient Scandinavian language and literature. (See **ICELAND, LANGUAGE AND LITERATURE OF**, and **NORWAY, LANGUAGE AND LITERATURE OF**.)

NORTH. I. **SIR THOMAS**, knight, an English author, 2d son of Edward, 1st Baron North, born about 1535, died subsequent to 1579. He published in 1579 a translation of "Plutarch's Lives," made from the French version of Amyot, and which was the first that appeared in England. Accompanying it were lives of other eminent men of Greece and Rome, collected from various sources, and the whole work was dedicated to Queen Elizabeth. He also published English versions of Guevara's *Horologium Principum* (fol., London, 1557), and Doni's *Filosofia morale* (fol., London, 1570). Beyond the record of his literary productions there is no account of his life. II. **SIR DUDLEY**, an English merchant, the 8d son of Dudley North, 4th Baron North of Kirtling, born May 16, 1641, died Dec. 31, 1691. After an education suitable to a mercantile career, he was bound an apprentice to a Turkey merchant, by whom he was sent to Smyrna as a factor. He subsequently took charge of a factory in Constantinople, and by a careful attention to his business, and a shrewd employment of his knowledge of the artifices of trade as well as of the peculiarities of the oriental character, amassed a fortune, with which in 1680 he returned to England. His experience in commercial affairs soon brought him into notice; and after serving as sheriff of London and alderman, he entered parliament in 1685 as member for Banbury, in which capacity he conducted the financial business of the lower house in be-

half of the lord treasurer. He was an unscrupulous adherent of the tory party, and brought himself into considerable disfavor by carrying a tax on tobacco and sugar. At different times he held the offices of commissioner of the customs and of the treasury. A few months before his death he published his "Discourses on Trade," a work highly praised by McCulloch, and the principal literary effort of his life. He has been characterized by Lord Macaulay as "one of the ablest men of his time," and as one in whom the government found "at once an enlightened adviser and an unscrupulous slave."

III. **ROGER**, brother of the preceding, born Sept. 8, 1651, died in 1733. He studied law in the Middle Temple, and became steward of the courts to Archbishop Sheldon. The statement that he was also attorney-general under James II. needs verification. He is chiefly known by his lives of his brothers, the lord keeper Guilford, Sir Dudley North, and Dr. John North, master of Trinity college, Cambridge, published after his death (2 vols. 4to., 1740-'3), and republished in 1826. He also wrote an "Examen" into the credit and veracity of Dr. White Kennett's "Complete History of England," a partisan work, but valuable for the insight it affords into the social and political condition of England under Charles II.; and left in manuscript "Memoirs of Music," commended by Dr. Burney, and which has been published by Dr. Rimbault (4to., London, 1846). Macaulay calls him "a most intolerant tory, a most affected and pedantic writer, but a vigilant observer of all those minute circumstances which throw light on the dispositions of men."

IV. **FRANCIS**, Lord Guilford, lord keeper of the great seal, brother of the preceding, born Oct. 22, 1687, died Sept. 5, 1685. He was educated at St. John's college, Cambridge, was called to the bar of the Middle Temple in 1661, and for several years travelled the Norfolk circuit. From the outset of his career he was indefatigable in his law studies, and, with a sort of dogged determination to achieve wealth and distinction at any sacrifice, he abstained from the ordinary pleasures of youth, and left untried no artifice and scrupled at no humiliation which would subserve his purposes. Sir Jeffrey Palmer, the first attorney-general under the restoration, early assisted him in getting into practice; and by "keeping fair with the cocks of the circuit," as his brother Roger North relates, "and particularly with Sergeant Earl, who had almost a monopoly," he became one of the leaders of the Norfolk circuit, and was soon retained in every important cause. Gaining the favor of the court by pleading against the privileges of parliament in the case of the prosecution of the 5 members, which had been brought into the house of lords on a writ of error from the court of king's bench, he was in 1671 appointed solicitor-general and knighted; and in Nov. 1673, he succeeded Sir Heneage Finch as attorney-general. In Jan. 1675, he was made

chief justice of the court of common pleas, in which position he conducted to a successful issue a dispute between his court and that of the king's bench as to the character and extent of the jurisdiction claimed by each. In 1679 he was admitted a member of the new council established by the king; and upon the retirement of Lord Nottingham in 1782, he was made keeper of the great seal. In Sept. 1683, he was created Baron Guilford of Guilford, Surrey. Throughout his judicial career he favored the prerogative, in accordance with the strong tory leanings of his family, and as a means also of advancing his own interests, of which he never lost sight; but toward the close of his life he suffered in political influence from the ambition and insolence of Jeffreys, and died broken down in spirit. His character and professional attainments are highly extolled by Roger North in his lives of the Norths; but according to Macaulay, this biographer, though under the influence of the strongest fraternal partiality, "was unable to portray the lord keeper otherwise than as the most ignoble of mankind." The same authority adds: "The intellect of Guilford was clear, his industry great, his proficiency in letters and science respectable, and his legal learning more than respectable. His faults were selfishness, cowardice, and meanness." Yet he had the courage shortly before his death to remonstrate with the king upon the dangers inseparable from his violent and arbitrary measures. He was the author of some scientific and miscellaneous papers, and of a few political essays published in his life by Roger North. V. FREDERICK, 2d earl of Guilford, better known by the title of Lord North, great-grandson of the preceding, and son of the 1st earl of Guilford, born April 18, 1728, died Aug. 5, 1792. He was educated at Eton and at Trinity college, Cambridge, made a lengthened tour on the continent, and in 1759 was appointed a commissioner of the treasury in the Pitt ministry. He entered parliament in 1761 from the family borough of Banbury, which he represented continuously for nearly 80 years. In 1768 he directed the proceedings which led to the expulsion of Wilkes, and in the same year supported the American stamp act and the right of the mother country to tax the colonies. Upon the formation of Lord Chatham's second ministry in 1766 he was appointed, jointly with Mr. George Cooke, paymaster of the forces, having refused to accept office under the previous Rockingham administration. Gaining in reputation and confidence as a legislator, he was appointed chancellor of the exchequer in the duke of Grafton's ministry, and upon the death of Charles Townshend assumed the position of leader in the house of commons. On the resignation of the duke of Grafton in 1770 he relieved the king from the embarrassment in which this event involved him by accepting the office of premier, and was rewarded by the unwavering attachment

and support of his royal master, continued through many years. His administration, extending from Jan. 1770, to March, 1782, in the language of an English writer, "teemed with calamitous events beyond any of the same duration to be found in our annals;" the American war being its great feature, and the efforts of the minister being directed principally to measures for the coercion of the revolted colonies. With the popular feeling against him, and an opposition in the house of commons unsurpassed in brilliancy of intellect and legislative ability, Lord North nevertheless for upward of 6 years contended almost single-handed with his parliamentary adversaries, repelling personal attacks, the most brilliant rhetorical displays or the bitterest shafts of satire, with imperturbable good nature, and a tact and readiness of wit which Burke once confessed exceeded that of the entire opposition. Although he never wavered in his opinion of the right of parliament to tax the colonies, it appears from the statement of his daughter, Lady Charlotte Lindsay, that during the last 8 years of his administration he entertained serious doubts as to the expediency of continuing the war, and was induced to persevere in the contest only in deference to the wishes of George III. Defeated in the house of commons on the question of the continuance of the war, he resigned office, and, after the short-lived administration of the marquis of Rockingham, joined his old antagonist, Fox, in breaking down that of Lord Shelburne which succeeded. In April, 1783, he returned to office as a joint secretary of state with Fox in the "coalition ministry" formed by the duke of Portland, the unpopularity of which caused its dissolution in the succeeding December. Soon afterward he retired definitively from public life. During the last 5 years of his life he was afflicted with total blindness, but endured this misfortune with unvarying cheerfulness. He succeeded to his title of earl of Guilford only two years before his death. Although a fluent and accomplished debater, he occupies a low rank as a statesman, having succeeded by a skilful distribution of official emoluments, rather than by any remarkable administrative ability, in retaining himself and his friends in power, and having failed during the 12 years that he held the premiership to originate a single measure entitling him to the gratitude or admiration of the English people. Burke has thus delineated his character: "He was a man of admirable parts, of general knowledge, of a versatile understanding, fitted for every sort of business; of infinite wit and pleasantry; of a delightful temper, and with a mind most disinterested." Gibbon, in the preface to his great history, says of him: "Were I ambitious of any other patron than the public, I would inscribe this work to a statesman, who, in a long, a stormy, and at length an unfortunate administration, had many political opponents, almost without a personal enemy; who has retained, in his fall

from power, many faithful and disinterested friends; and who, under the pressure of severe infirmity, enjoys the lively vigor of his mind and the felicity of his incomparable temper."

NORTH CAPE. See **CAPE NORTH.**

NORTH CAROLINA. See **CAROLINA, NORTH.**

NORTH CAROLINA, UNIVERSITY OF, an institution of learning at Chapel Hill, Orange co., N. C. It was incorporated in 1789, Samuel Johnston and others being appointed trustees. In 1792 the location was fixed upon, and in Oct. 1798, the corner stone was laid, 1,180 acres of land having been conveyed to the trustees by the citizens of the neighborhood. The Rev. David Kerr was appointed professor and Samuel A. Holmes tutor, and it was opened for public instruction, Feb. 18, 1796. Mr. Kerr soon retired from his position, and was succeeded by Charles W. Harris, on whose resignation Joseph Caldwell was appointed in the autumn of 1796, and presided over the university for nearly 40 years. In 1804 he was appointed president of the university, and on his death in 1835 David L. Swain, LL.D., the present incumbent, succeeded. The faculty comprises 15 instructors; the present number of students is 450, and the college possesses a library of 21,000 volumes. The endowment of the university consists of about \$150,000 invested in stocks, and about as much more in buildings. The trustees are appointed by the legislature, but no appropriations for the support of the university are made from the state treasury. Tuition is \$50 per annum, but since 1836 any native of the state of good moral character, who is unable to pay, may have his tuition fee remitted, there being no other free scholarships. The two literary societies ("Dialectic" and "Philanthropic") generally support from one to three beneficiaries each. Connected with the college is a law school with two professors, and also a scientific school established in 1853 with two professors.

NORTH RIVER. See **HUDSON RIVER.**

NORTH SEA, or GERMAN OCEAN, an extensive arm of the Atlantic which lies between Great Britain and the continent of Europe, extending from lat. 51° to 61° N. and long. 2° 30' W. to 7° 30' E.; extreme length about 700 m., breadth 400 m. It has the Atlantic ocean on the N.; Norway, Denmark, Hanover, Holland, Belgium, and the N. extremity of France on the E. and S. E.; and the strait of Dover, England, Scotland, and the Orkney and Shetland islands on the S., S. W., and W. The shores are deeply indented by numerous bays, inlets, and estuaries, the chief of which are the firths of Hardanger, Bommel, Bukke, and Flekke on the coast of Norway; the Skager Rack and Cattagat, which communicate between the North sea and the Baltic; the firths of Liim, Nissum, and Staving, and the estuaries of the rivers Varde and Eider, in Denmark, and those of the Elbe, between Denmark and Hanover, and the Weser in the latter country; the Zuyder Zee and the mouths of the Meuse and

Scheldt in Holland; the estuaries of the Thames, Humber, and the Wash in England; and the firths of Forth and Moray in Scotland. Beside the islands which have been already mentioned as forming the W. boundary of the North sea, there are many others, all however within short distances of the coasts of Norway, Denmark, and Holland. The most important are those of Stor Sartorse, Bommeloe, and Karmoe, in Norway; Fanoe, Römoe, Sylt, Fohr, Amrom, Nordmarsch, Pelworm, and Nordstrand in Denmark; Neuwerk and several smaller in Hanover; Helgoland, which belongs to England, opposite the mouth of the Elbe; Borkum, Rottum, Schiermonnikoog, Ameland, Ter Schelling, Vlieland, Texel, and the islands formed by the deltas of the Meuse and Scheldt, in Holland. The Bell rock and May rock, on each of which there is a lighthouse, are the only islands of the North sea upon the coast of Great Britain. Floating lights have been established upon several banks, and there are lighthouses at all the principal points and ports upon its coasts. The average depth of the sea is about 30 fathoms, but toward the Norwegian side the soundings increase to 190 fathoms. The North sea is traversed by several extensive banks. The Dogger bank, which is the principal, lies about the centre, between lat. 54° 10' and 57° 24' N., and long. 1° and 6° 7' E.; another bank extends 110 m. in a N. E. direction from the firth of Forth, and one runs 105 m. N. W. from Jutland in Denmark. The tidal wave which comes from the Atlantic passes along the W. coasts of Great Britain and Ireland, and enters the North sea by its N. extremity, continuing to rule the tides as far S. as the N. end of the strait of Dover, and, through this strait, to be felt in some degree in the English channel. Upon the N. coast of Scotland the rise is about 12 feet, and increases, according to the figure of the shore, to 20 feet at the Humber and 18 at Dover. The portion of the tidal wave which is intercepted by the English channel as it comes from the S. passes directly through that channel, and meets the tide of the North sea about the N. extremity of the strait of Dover; and when the two floods meet, the S. is half a day earlier than the N.; or, in other words, the N. wave is part of the tide preceding the one from the S. which it meets; that time, and the interval taken by the tide in passing through the English channel, in all about 18 hours, being occupied by the tidal wave in making the complete circuit of Great Britain.—Several thousand people are occupied in the fisheries in the North sea, and the quality of the fish has long been celebrated. The chief kinds taken are cod, ling, hake, turbot, soles, different sorts of flat fish, lobsters, and immense quantities of mackerel and herrings.

NORTH-WEST PASSAGE. See **ARCTIC DISCOVERY,** and **MACCLINTOCK, SIR F. L.**

NORTH-WESTERN PROVINCES, or **AGRA,** a lieutenant-governorship of British India, sub-

ordinate to the presidency of Bengal, lying between lat. $23^{\circ} 51'$ and $30^{\circ} 36'$ N., and long. $75^{\circ} 20'$ and $84^{\circ} 40'$ E. Its name does not accurately describe its position, for it occupies about the centre of the N. part of Hindostan. It comprises the following divisions and districts:

Division.	District.	Area in sq. m.	Population.
Meerut.....	Faharunagar.....	2,165	857,388
	Masuramagar.....	1,617	573,361
	Meerut.....	2,000	1,125,073
	Bodlandshahar.....	2,000	778,368
	Allypore.....	2,140	1,134,305
Bulandshahr.....	Bijaypur.....	1,904	680,361
	Moradabad.....	2,907	1,125,461
	Budayeen.....	2,000	1,819,141
	Bareilly and Philibhoet.....	2,007	
	Shahjahanpur.....	2,400	
Agra.....	Muttra.....	1,007	
	Agra.....	1,804	
	Farrukhabad.....	1,800	
	Mynpoorie.....	2,000	
	Rawah.....	1,074	
Allahabad.....	Cawnpore.....	2,007

Benares.....	Gorakhpore.....	7,346	2,007,074
	Azimgarh.....	2,000	1,000,361
	Jounpore.....	1,800	1,148,740
	Mirzapore.....	2,000	1,104,315
	Benares.....	904	651,197
Total.....	Champur.....	2,107	1,800,304
		81,045	27,000,305

The Lieutenant-governor also has jurisdiction over the non-regulation provinces and territories (so called because they have been only partially brought under the British system of government) of Sangor and Nerbudda, Butty, Kote Kasim, Jannar and Bawar, Deyrah Doon, Kumaon, Ajmeer, and British Nemaar. There are no returns of the area and population of most of these. The Delhi division, including the districts of Paniput, Hurriana, Delhi, Rohtuk, and Georgaon; the Cis-Sutlej territory (Ferozepoor, Ludiana, Umballa, and Kythul); and the Punjab or Trans-Sutlej states, formerly belonged to the North-Western provinces, but in 1859 were erected into a new lieutenant-governorship under the title of the Punjab and its dependencies. The greater part of the lieutenant-governorship is a compact territory, bounded N. by the Himalaya and Nepal, E. by Bengal, S. by Rewah, the Bundelcund states, the dominions of Sindia, Bhurtpoor, and some petty native territories, and W. and N. W. by the Punjab and its dependencies. The province of Oude is bounded by it on 3 sides, Nepal lying on the 4th. There are several detached tracts, one very large one lying between Bundelcund and Nagpoor, and including most of the non-regulation provinces. The North-Western provinces lie chiefly in the great plain of Hindostan, though the northern portions, situated within the Himalaya regions, are broken by spurs of the great snowy range, and the S. part is crossed by the Vindhya mountains. Along the S. base of this latter chain flows the river Nerbudda, and between the two hilly re-

gions are the basins of the Ganges, the Jumna, and the Chumbul. The principal other rivers are the Soane, Betwah, Goomtee, and Gogra, all affluents of one or another of the preceding 3 great streams. The remaining physical characteristics and productions of the provinces will be found described under the names of the separate districts. The lieutenant-governor is appointed by the governor-general in council, and his seat of government is Agra. During the sepoy mutiny in 1857 the North-Western provinces were the principal theatre of war. (See HINDOSTAN.)

NORTHAMPTON. I. An E. co. of Penn., bounded E. by the Delaware river, which separates it from New Jersey, and intersected toward the S. by the Lehigh river; area, 870 sq. m.; pop. in 1850, 40,385. The Kittatinny or Blue mountains form the N. W. boundary, and the South mountain is on the S. E. In the valley between them are beds of valuable limestone, quarries of slate, and several iron mines. The productions in 1850 were 188,668 bushels of Indian corn, 105,147 of wheat, 46,980 of oats, 7,126 tons of hay, 2,756 lbs. of wool, and 205,100 of butter. There were 84 grist mills, 15 saw mills, 2 iron furnaces, 7 foundries, 1 cotton factory, 24 tanneries, 8 newspaper offices, 46 churches, and 7,348 pupils attending public schools. Several railroads and 2 canals meet at the capital, Easton. II. A S. E. co. of Va., forming the S. extremity of the peninsula lying between Chesapeake bay and the Atlantic ocean; area, 820 sq. m.; pop. in 1850, 7,490, of whom 2,648 were slaves. The coast line on the W. is indented by numerous inlets, and on the E., in the Atlantic, there are several small islands. The surface is level and the soil light and sandy. The productions in 1850 were 264,957 bushels of Indian corn, 184,087 of oats, 795 of wheat, 44,189 of sweet potatoes, and 7,756 lbs. of wool. There were 26 grist mills, 8 castor oil mills, 2 saw mills, 10 churches, and 622 pupils attending public schools. Value of real estate in 1856, \$1,390,033, being an increase of 8 per cent. since 1850. Capital, Eastville. III. A N. E. co. of N. C., bounded N. by Virginia, and S. W. by the Roanoke river; area, about 250 sq. m.; pop. in 1850, 13,335, of whom 6,511 were slaves. It has a diversified surface and generally fertile soil. The productions in 1850 were 657,951 bushels of Indian corn, 1,378 bales of cotton, and 27,100 lbs. of tobacco. There were 15 grist mills, 2 saw mills, 6 stove manufactories, 1 shingle mill, 8 churches, and 173 pupils attending public schools. The county is intersected by the Seaboard and Roanoke and the Greenville and Roanoke railroads. Capital, Jackson.

NORTHAMPTON, a township and village, the capital of Hampshire co., Mass., about 1 m. W. from the Connecticut river, and on the Connecticut river railroad, 17 m. N. from Springfield and 95 m. W. from Boston; pop. of the township in 1860, 6,813. The village is situated on elevated ground in the midst of a

beautiful country, having Mts. Tom and Holyoke in full view. It contains the county buildings, 2 banks, and several educational institutions of reputation, among which is the Northampton collegiate institute; and in 1860 there were 7 churches, viz.: 1 Baptist, 2 Congregational, 1 Episcopal, 1 Methodist, 1 Roman Catholic, and 1 Unitarian. There are several important manufactories, including 1 cotton mill, 1 tool factory, 8 paper mills, and 2 silk manufactories. A fine bridge over the Connecticut, 1,230 feet long and 26 feet wide, connects the town with Hadley.

NORTHAMPTON, a municipal and parliamentary borough and market town of England, capital of Northamptonshire, situated on the left bank of the Nen, 67 m. from London by railway; pop. in 1851, 80,544. It occupies the summit of an eminence rising from the river, over which there are several bridges. The principal manufactures are boots and shoes, in which about 2,500 persons are employed. There are iron and brass foundries, flour mills, breweries, and coach factories.

NORTHAMPTONSHIRE, an inland and central co. of England, surrounded by the counties of Lincoln, Cambridge, Huntingdon, Bedford, Buckingham, Oxford, Warwick, Leicester, and Rutland; area, 1,016 sq. m.; pop. in 1851, 212,880. The principal rivers are the Nen, Welland, and Avon. The surface is undulating, belonging to the basin of the Nen and watered by numerous rivulets. The N. E. extremity of the county belongs to the great fen district, and is only a few feet above the sea. The county is well wooded with oak, ash, beech, and elm. The climate is mild and healthy. The chief agricultural pursuit is stock raising. There are no manufactures of any importance, except boots and shoes. The county returns 8 members to the house of commons, 4 of whom are for its boroughs. It has railway communication with all parts of the country. There are two principal canals, the grand junction canal and the grand union canal.

NORTHOOTE, JAMES, an English painter and author, born in Plymouth, Oct. 22, 1746, died July 18, 1831. He was the son of a watchmaker, with whom he served an apprenticeship; after which, in accordance with a decided taste for art, he devoted himself to painting. In 1771 he was admitted by Sir Joshua Reynolds into his house as a pupil. In 1777, having acquired some proficiency in portrait painting, he repaired to Italy, and for 8 years studied the works of Titian, Michel Angelo, and other great masters of historical art. Returning to London in 1780, he became, through necessity rather than choice, a portrait painter, until the establishment of Alderman Boydell's "Shakespeare Gallery" gave his pencil employment in a higher walk of art. For this collection he painted "Prince Arthur and Hubert," "The Murder of the Princes in the Tower," "The Death of Wat Tyler," and "The Entry of Bolingbroke and Richard II. into

London;" works which gained him considerable reputation. In 1787 he was elected an academician. For a number of years he pursued a prosperous career as a painter of portraits and history, but was gradually supplanted. He then tried fancy pieces, and also painted a series of moral pictures, entitled "The Modest Girl" and "The Wanton," which failed to make an impression. As he advanced in life he grew perceptibly less amiable, and his sarcasms and harsh criticism of the productions of contemporary artists made him exceedingly unpopular. He continued painting portraits until near the close of his career; but his pictures were eclipsed by those of Lawrence and Jackson. As an author, Northcote was known by a "Life of Sir Joshua Reynolds" (4to., London, 1813; with supplement, 1815; 8vo., enlarged, 1819), valuable chiefly for the sayings and anecdotes of Reynolds; "Life of Titian" (2 vols. 8vo., 1830), the joint production of himself and Haslitt; and two volumes of fables, of which the first, entitled "One Hundred Fables" (8vo., 1838), contained original and selected pieces, with illustrations from his own designs; and the second, also illustrated by himself, was published after his decease under the title of "The Artist's Book of Fables." He is said to have been a pungent and entertaining converser, and, according to Leslie, "talked better than he painted."

NORTHERN LIGHTS. See **AURORA BOREALIS**.

NORTHMEN, and **NORMANS**, names usually given, the former especially to the ancient and mediæval inhabitants of Scandinavia, or Denmark, Norway, and Sweden, and the latter to that portion of them who conquered and settled in Normandy. In history Scandinavia has no place anterior to the discoveries of Pytheas, about 320 B. C. Thule, of which he heard when in Britain, was in all likelihood western Scandinavia, and the southern shores of Sweden. Tacitus (about A. D. 100) speaks of northern pillars of Hercules, meaning possibly the coasts of the strait of Elninora. All, however, was conjecture; and all was soon lost in oblivion, or looked upon as fabulous. Pliny visited the shores of the North sea, and notices Nerigon (Norway). He appears to have gathered none but fabulous accounts of regions beyond the Baltic. Tacitus speaks of Suiones (Swedes) in the ocean, "strong in numbers, arms, and ships." Ptolemy the geographer (2d century A. D.) knew of Goths and Danes. Although nothing appears to warrant an idea that Scandinavia of old was at any time so populous as it is now, it is yet certain that it held a larger population than it could feed and employ; and hence the incessant piratical expeditions of the sea kings, and hence also a well known law of early Scandinavia, which ordained that certain members of each family should by lot annually seek their fortunes abroad. The father drove forth his sons on attaining manhood, with the exception of the

eldest, who was heir to the estate. The Goths went forth first from Scandinavia in but 3 ships; and it is abundantly proved that it was not until vast communities had been thus formed on the southern shores of the Baltic, that they became the mighty people who were the terror of Rome. An opinion once generally prevailed that Sweden was the original home of the Goths. Another theory, of legendary origin, is that the Caucasus was their more ancient home, and that several migrations thence had preceded Odin and his Suiones, who came into Sweden about A. D. 70. Scandinavia was first laid open to the rest of Europe by Christianity. Scandinavian histories, eddas, and sagas had preserved mythical details of several previous centuries; and from these narratives, which have exercised the ingenuity of learned men, we gather that Scandinavians proper, subsequent to the exodus of the Goths, were drawn into maritime expeditions by Saxons and other tribes on the Elbe, who early in the 5th century had effected their English conquests. As early as 787 the Danes made incursions along the English coast. In 835 they were vanquished in a great battle by an Anglo-Saxon king, Egbert; but 40 years later, in the reign of Ethelred, a footing was established, and the Danes mastered Northumberland and other districts. They were temporarily held in check by Alfred the Great; but the Anglo-Saxon resistance grew feeble, and in 991 the Danes first exacted their tribute tax, the *Danegelt*. Four Danish sovereigns, among whom was Canute the Great, reigned in England during the next 50 years, down to 1042. As early as 852 the Scandinavians had a king in Dublin, and there were princes of the same race governing petty sovereignties at Waterford and Limerick. This rule appears to have continued as late as the invasion of Ireland by Henry II. of England. The Shetland isles and the Hebrides were early conquests of the Northmen. Scotland was visited by them at different periods between the 8th and 11th centuries. They were at length defeated and a large army cut to pieces in the reign of King Duncan, by the Scots commanded by Macbeth and Banquo. Further off, the Northmen, tempest-driven, or led on by thirst of discovery, found vast regions where they planted their language and civilization without opposition. Iceland was first discovered in 860 by Naddod, a Norwegian pirate. Returning from the Färöe islands, Naddod was driven off to the N. W., and saw an unknown, inhospitable-looking coast, which he named Snowland (Snóland). He was followed by a Swede, Gardar Svarfason, who ascertained that it was an island. Four years later a sea rover from Norway came upon it and named it Iceland (Is-land). Its appearance was too forbidding to invite a prolonged visit. His companions, however, differed with him so entirely in their report of its aspect, and spoke so extravagantly of a delightful climate and fertile soil, "with milk from every plant and butter

from every twig," that a Norwegian jarl who was banished from home, or rather compelled to fly from the vengeance of a race whose chief he had slain, took refuge in the new-found island. He was accompanied by his dependants, and established a colony (874). All the habitable parts of the island were speedily occupied by reinforcements from home. The ancient Scandinavian idiom, long preserved in Iceland, is still the language of its peasants. — Discoveries in the western Atlantic soon followed that of Iceland. About 982 a jarl of Norway, exiled for murder, withdrew with his son Eric the Red to Iceland. The son in 986 was forced to leave Iceland for the same cause; and wandering far away to the S. W., he saw land, and entered a deep bay which he called Eric's fiord. He named the country Grönland (Greenland), and founded a colony, which flourished until the 14th century, and continued to exist until the 15th.—We come now to the saga narratives of the discovery of America. Heriolf, a descendant of Ingolf, the first colonist of Iceland, was separated from his son Biorn by some accident at sea. They were traders. The son, roaming about the ocean in search of his father, was driven far westward in a prolonged gale, and at length saw land—a wide, flat, woody region, terminating in a cape, which Biorn doubled; and taking then a west wind, he put back to sea for Greenland. Here the first discoverer of America, satisfied to find his parent, thought little of his other adventure. He had seen a northern cape of the gulf of St. Lawrence. In the following year (1002), Leif, son of Eric the Red of Greenland, resolved to pursue the adventure. His father would have taken command of the cruise, but was deterred by an evil omen. Leif set sail with 35 men, and reaching the distant coast, steered along it in a S. direction until he came to a pleasanter region, which he called Markland, or the country of the wood. Pursuing his voyage, he discovered a still more inviting anchorage, and found the country undulating and woody, abounding with fruit and berries. There were also a river and lake filled with salmon. They here pitched tents and built huts; and having found abundant grapes, they called the place Vinland. Leif passed a winter there, and in the spring sold his vessel to a brother, Thorwald, who likewise remained a winter on the spot of Leif's encampment, and in the spring explored the coast westward, finding a beautiful region, and a single trace of inhabitants—a corn shed built of wood. He passed a second winter in Vinland; and in the following summer, after further explorations toward the E. and N., chose a spot for his abode. Here they found natives with canoes, and Thorwald was killed in a skirmish. His survivors drove off the natives and passed a third winter in Vinland. The natives resembled the Esquimaux, already known in Greenland. New adventurers followed upon the

trace of these pioneers. In 1007 a rich Greenland, Thorfin, determined to emigrate to Vinland. His followers numbered 60, and he was accompanied by his wife, Gudrida, the widow of a previous explorer. Five other women were on board; and the ships were freighted with all kinds of domestic animals, tools, and provisions for a permanent colony. Gudrida had been the first female to see the new world, having accompanied her former husband during the previous year. The expedition of Thorfin prospered. The natives came in great numbers, and trafficked in furs and produce. Gudrida bore a son, Snorro, the first birth of European parentage in America, who has been said to have been an ancestor of the sculptor Thorwaldsen. The family remained 8 years in the colony, but ultimately returned, and Thorfin settled and died in Iceland. The widow made a pilgrimage to Rome in her bereavement, and died in a cloister founded by her son in Iceland. Other chiefs went to Vinland, but their history throws no further light upon the colony. They however discovered land extending far away to the S. W., and inhabited by natives of different caste, of darker color and more vigorous frame. The colony perished at last, destroyed probably like that of Greenland. Traces of it were found by Jesuit missionaries among the Indians of Gaspé at the mouth of the St. Lawrence, a tribe which revered the symbol of the cross before the arrival of the missionaries. Physical constitution and peculiarities of manners and customs are also cited in confirmation of European descent. Father Charlevoix adds that "many marks distinguishing them from other American Indians, go far to make me believe that they are a colony of Europeans degenerated into savages through destitution." There are many corroborations of the truthfulness of the Icelandic chronicles, from which the foregoing narrative is derived, and which are sustained by a continental historian almost contemporary with the expedition of Thorfin. This was Adam of Bremen, a priest who was entertained for a long time at the Danish court, where the American discoveries were as well known as in Iceland. Two Venetian navigators assert that they visited the American coast, in the service of a prince of the Orkneys, toward the close of the 14th century, and collected relics of the old Icelandic colonies.—The Russian coast, although peopled by races more warlike than the nations of the south and west, were colonized by Scandinavians at a very early period. Russia appears frequently in the sagas, under the names Ostrogardia and Gardariki; and Runic inscriptions prove that the Northmen had been in Russia long before the introduction of Christianity. They received from the native tribes the name of Varangians, Varangars, or Væringjar, sea rovers, an ancient Swedish term for wolves. Rurik occupied Novgorod about the year 865, and gave to his followers the best lands of the subdued inhabitants. He founded

the dynasty which gave sovereigns to Russia until the close of the 16th century. Two of Rurik's captains penetrated to Kiev, whence the Dnieper showed the way to the Black sea and the Bosphorus. At the end of the 11th century the Byzantine emperor had 700 Varangians from Kiev for his body guard; and from this period until the fall of the eastern empire, the Byzantine sovereigns trusted their lives to no other household troops. The *Codex Flateyensis* of Iceland gives the number of the Varangian guard in the 11th century at 800; and they are described by Gibbon (chap. 55) as "retaining to the last the inheritance of spotless loyalty." Harald Hardrada, a captain of the guard during the reign of the empress Zoe, returned to Russia, married a daughter of the czar, and became king of Norway. His adventures are the foundation of Oehlenschläger's tragedy of the "Varangians in Constantinople." Among the antiquities in the museum of Christiania are Byzantine coins of 842–867, found in ploughing the fields of Aggerhuus in Norway.—A Danish invasion penetrated to the Meuse in 515, and was repelled. The victories of Charlemagne over the Saxons provoked at length a league between that people and the Danes. Gottfried, king of Jutland, at the head of pirate bands, ravaged the French and Spanish coasts, even within the strait of Gibraltar. Their great invasion of France, however, was delayed until after 841; from which period the whole coast of western Europe from the Elbe to the Guadalquivir was a prey to the Northmen. In 887 they had sacked Utrecht and Antwerp, and fortified themselves on the island of Walcheren, spreading themselves on the mainland. Flanders was obstinately defended; but Friesland, lower Lorraine, and Neustria fell without resistance. Rollo devastated Holland, and appeared upon the Seine, while Gottfried ravaged the valleys of the Meuse and Scheldt. They burned and sacked Cologne, Bonn, Treves, Metz, and other cities, stabling their horses at Aix la Chapelle in the cathedral church of Charlemagne. *A furor Normannorum libera nos, Domine*, came to be part of the Catholic litany. Hastings, at the head of a band of Northmen, sacked Bordeaux, Lisbon, and Seville; defeated the Moorish conquerors of Spain at Cordova; crossed the straits into Morocco; repassed them; overran Tuscany; returned to France, where other chieftains had had various success against Charles the Bald, and embraced Christianity. (See *HASTINGS*.) His name, the most dreaded of all the vikings, was adopted by many successors. With safe winter quarters in Spain, they extended their ravages to Naples, Sicily, and the coasts of the Greek empire. Anarchy meanwhile prevailing in France, in the autumn of 885 they laid siege to Paris. After a year the siege was converted into a blockade, but at last King Charles the Fat bought off the Northmen with 700 pounds of silver, and a free passage to the upper Seine and Burgundy. The most redoubtable of the Northmen afterward was

Hrolf, better known as Rollo, an exiled robber chieftain of Norwegian parentage, first duke of Normandy, and direct ancestor, in the 6th generation, of William the Conqueror. In the words of Snorro Sturleson: "He was so mighty of stature, that there was no horse of strength and size to bear him. He was therefore always on foot, and was called Rollo the marcher." He ravaged Friesland and the countries watered by the Scheldt, and took Rouen, St. Lô, Bayeux, and Evreux. From Charles the Simple he accepted the hand of a daughter, together with a tract of Neustrian territory N. of the Seine from Andalys to the sea (modern Normandy), in exchange for Christian baptism and an oath of fealty (912). Thus was arrested the Scandinavian flood which had devastated France for more than a century. Rollo distributed among his followers the lands of Neustria, to be held of him as duke of Normandy. Thus were laid the foundations of the feudal system which William (7th duke) transplanted into England (1066-87). Few external traces of the Scandinavians are to be found in modern Normandy. Yet for a time the Scandinavian gods divided with the Saviour the religious reverence of the people of that country. Monasteries and cathedrals were built however, with what extent and magnificence their splendid remains attest. The Normans adopted the language of the vanquished province, but greatly modified it. It was the *langue d'oïl* (the *langue d'oïl* being south of the Loire), which became under Norman inspiration the peculiar medium of romantic poetry.—The history of the Northmen at home, their kings and governments, will be found under DENMARK, NORWAY, and SWEDEN. The race of Anglo-Saxons belongs rather to the Teutonic than the Scandinavian family. Britain, deserted by the Romans, was subdued by Saxons, Angles, and Jutes (Jutlanders). The last in small numbers were the only really Scandinavian ingredient of the blended nation. The Angles from Schleswig left their country a desert; and although thus allied with Scandinavia, their origin and language were Teutonic. The Saxons, the predominating race, were natives of the country between the Elbe and the Eider (Holstein and Lauenburg).

NORTHUMBERLAND. I. A central co. of Penn., bounded W. by the Susquehanna river and its West branch, intersected by the North branch, and drained by Shamokin, Mahanoy, and other creeks; area, 457 sq. m.; pop. in 1860, 29,057. Its surface is mountainous, particularly in the south, and the soil of the valleys is generally very fertile. The productions in 1860 were 289,522 bushels of wheat, 282,087 of Indian corn, 194,676 of oats, 20,810 tons of hay, 26,670 lbs. of wool, and 501,619 of butter. There were 26 grist mills, 5 saw mills, 4 iron foundries, 16 lime kilns, 15 tanneries, 4 newspaper offices, 52 churches, and 8,900 pupils attending public schools. The county is traversed by the North Branch canal; and the Shamokin

valley and Pottsville and the Sunbury and Erie railroads have their terminus at the capital, Sunbury. II. An E. co. of Va., at the mouth of the Potomac, bounded E. by Chesapeake bay; area, about 200 sq. m.; pop. in 1860, 7,346, of whom 3,755 were slaves. It has an undulating surface, with a moderately fertile soil. The productions in 1860 were 221,857 bushels of Indian corn, 53,902 of wheat, 15,093 of sweet potatoes, 8,586 lbs. of wool, and 29,773 of butter. It contained 23 grist mills, 6 saw mills, 3 tanneries, 11 churches, and 279 pupils attending public schools. The value of real estate in 1866 was \$1,176,618, showing an increase of 23 per cent. over 1850. Capital, Heathsville.

NORTHUMBERLAND, a central co. of Canada West, on Lake Ontario; area, 780 sq. m.; pop. in 1851, 81,229. It is drained by small streams, some of which flow from Rice lake on its N. border. The grand trunk railway runs along its S. border; its capital, Cobourg, is connected by railroad with Peterborough.

NORTHUMBERLAND, a N. E. co. of New Brunswick, bordering on the gulf of St. Lawrence, and drained by the river Miramichi; area, 4,800 sq. m.; pop. in 1851, 15,064. It is abundantly watered, has a diversified surface, very heavily timbered, exports large quantities of lumber, and possesses valuable fisheries. Capital, Miramichi.

NORTHUMBERLAND, the northernmost co. of England, bounded N. W. by Scotland, from which it is partly separated by the river Tweed, E. by the North sea, S. by Durham and Cumberland, and W. by Cumberland; area, 1,952 sq. m.; pop. in 1851, 303,568. On the W. it is mountainous, being covered by the Cheviot hills; but along the coast it is level with a highly fertile soil. The Tyne, Wansbeck, Blyth, Coquet, Aln, Till, and Tweed are the principal streams, the first and last being the most important, not only for their superior facilities for navigation, but for their abundance of salmon. The county contains vast quantities of coal, frequently found together with limestone, lead ore in the mountains to the S. W., iron ore in various parts, and many excellent qualities of stone. The principal agricultural products are wheat, oats, and barley; and the science of agriculture has been so highly developed that it has become a school to which many resort. Coal and iron are the bases of most of the manufacturing operations. It is traversed by two lines of railway, the Newcastle and Carlisle and the Newcastle and Berwick. Interesting remains of the Roman era, including the famous wall, exist, and there are a number of ruined castles which attract much attention. The principal towns are Newcastle, Tynemouth, North Shields, Morpeth, and Alnwick. Northumberland returns 8 members to parliament, 4 for the county, 2 for the borough of Newcastle-upon-Tyne, and 1 each for Morpeth and Tynemouth.

NORTHUMBERLAND, DUKE OF. See DUDLEY, vol. vi. p. 650.

NORTON, ANDREWS, an American scholar and theologian, born in Hingham, Mass., Dec. 31, 1786, died in Newport, R. I., Sept. 18, 1853. He was graduated at Harvard college in 1804, and commenced immediately his preparation for the clerical profession. In 1809 he became a tutor in Bowdoin college, and in 1811 a tutor in mathematics in Harvard college. In 1813 he was appointed librarian of the university at Cambridge, and in the same year succeeded the Rev. Dr. O'hanning as lecturer on biblical criticism and interpretation, on the foundation created under the will of the Hon. Samuel Dexter. In 1819, on the organization of the divinity school as a separate department of the university, he was chosen Dexter professor of sacred literature, and, resigning the office of librarian in 1821, continued in the discharge of the duties of his professorship till 1830. The remainder of his life was passed for the most part in retirement, in feeble and gradually declining health, but with a degree and amount of diligence as a student and an author seldom exceeded by persons of the most vigorous constitution. In his theological views and writings Mr. Norton united opposite schools of thought, and belonged by an almost equal title to the extreme right and the extreme left as to matters of religious belief. He was radical as a critic and interpreter, conservative as an expositor of Christian doctrine. He applied to the sacred writings not only the severest recognized tests of genuineness and authenticity, but equally his own exacting taste and fastidious judgment, thus rejecting on internal grounds, and not infrequently for reasons peculiar to himself, many passages generally received as belonging to the true text of Scripture. But what he regarded as the original record of Christ's life and words he held in the most profound reverence. Thus, while he led the van in the Unitarian protest against Calvinism, he was foremost in opposition to the naturalistic school of which Theodore Parker was the principal representative. In his early life he frequently appeared in the pulpit; but though his thought was profound and his utterance impressive, he lacked vivacity of style and manner. As a lecturer on the interpretation of Scripture he can have had in this country few equals, and no superior, in clearness of conception, perspicuity of statement, affluence of illustration, and in the union of searching, unsparing criticism with the profoundest devotional feeling. In applying, with a hand that never shrank from its work, the probe and the scalpel to the sacred record, he made it manifest that his sole object was to reach and lay bare the vital truth of revelation. In 1819 he undertook the editorship of "The General Repository and Review," a periodical mainly designed to illustrate and defend the views of the liberal school of theology. The work was admitted on all hands to be conducted with eminent ability; but its boldness in the championship of doctrines generally deemed heret-

ical deprived it of the popular favor, and at the end of the second year it was discontinued for want of adequate support. In 1833 he published "A Statement of Reasons for not believing the Doctrines of Trinitarians concerning the Nature of God and the Person of Christ," which holds its place as an unrivalled vindication of the humanitarian theory as to the nature of Christ. In 1837 appeared the first volume of his elaborate work on "The Genuineness of the Gospels," which was followed in 1844 by the 2d and 3d volumes, devoted principally to the history of Gnosticism. The object of this work is to defend the authorship of the Gospels by the men whose names they bear against the theory of their late and gradual formation. A 4th volume, on the internal evidences of the genuineness of the Gospels, nearly prepared for the press, appeared after his death. He left in readiness for publication a "Translation of the Gospels," which was published after his death, with a supplementary volume of notes, in part designed by him to accompany the translation, and in part selected from his published works and his miscellaneous manuscripts. Of his other literary labors, those which attracted the most attention were his inaugural discourse on assuming the duties of his professorship, and his address to the alumni of the divinity school, in 1839, "On the Latest Form of Infidelity." He contributed many valuable articles to the "North American Review" and the "Christian Examiner." He also edited, in 1838-'4, in connection with Mr. Charles Folsom, "The Select Journal of Foreign Periodical Literature." His poetical talent, if cultivated, would alone have made him eminent. His poems were few, but of rare beauty in conception, imagery, and rhythm; and some of his devotional hymns are among the choicest lyrics in our collections of sacred psalmody.

NORTON, CAROLINE ELIZABETH SARAH, an English poetess, born in 1808. Her father, who died when she was 9 years old, was a son of Richard Brinsley Sheridan, and her mother was a granddaughter of the earl of Antrim. She received an excellent education, and from childhood had so strong a passion for writing that her mother judged it necessary to deny her the use of pen and paper. Her first publication was a short satirical piece called "The Dandies' Rout," which appeared while she was yet a school girl. In July, 1827, she was married to the Hon. George Chapple Norton, brother of the present Lord Grantley. The union was not a happy one, and in 1836 a quarrel occurred under circumstances which excited much public comment. She was accused of adultery with Lord Melbourne, then prime minister, but was acquitted after an exciting public trial. In her lines "To the Duchess of Sutherland," Mrs. Norton feelingly alludes to the slanders to which she was subjected on this occasion. Her first volume of poems, comprising among others "The

Sorrows of Rosalie," written in her 17th year, appeared anonymously in 1829, and met with general favor. "The Undying One" (1830), founded on the legend of the wandering Jew, achieved a still greater success. It was followed by "A Voice from the Factories" (1836); "The Dream, and other Poems" (1840); and "The Child of the Islands" (1845). In the last mentioned poem she calls the attention of the prince of Wales to the want of communication and sympathy between the higher and lower classes of society. Mrs. Norton has interested herself warmly in several social problems, particularly such as affect the condition of the poor and the position of women, and has written "English Laws for English Women in the 19th Century" (privately printed, 1854); "A Letter to the Queen on Lord Chancellor Cranworth's Marriage and Divorce Bill" (1855); and a series of letters to the "Times" on philanthropic subjects. In prose she has also published two novels, "The Wife, and Woman's Reward" (1835), and "Stuart of Dunleith, a Story of Modern Times" (1847), which gave evidence of great powers as a novelist; but the latter work was of too painful an interest to become permanently popular. Mrs. Norton is the author of "Aunt Carry's Ballads" (1847), a Christmas book for children; and she has written largely for annuals and magazines. In 1850 she collected some of her miscellaneous contributions to periodicals under the title of "Tales and Sketches in Prose and Verse." The most striking characteristics of Mrs. Norton's poetry are passion, force of diction, and at times remarkable tenderness. She has lately been engaged in writing the "Lives of the Sheridans," her paternal ancestors, which is expected to appear in 1861.

NORTON JOHN, an American clergyman, born at Stortford, Hertfordshire, England, May 6, 1606, died in Boston, Mass., April 5, 1663. He was educated at Cambridge university, and was afterward curate in his native town. Having embraced Puritanism, he came to Plymouth, New England, in Oct. 1635, and preached there during the winter. In 1636 he went to Boston, and before the close of the year became minister of the church at Ipswich. In 1652 he returned to Boston. He and Gov. Bradstreet were the two agents sent from the colony in 1662 to address Charles II. after his restoration. The king assured them that he would confirm the charter, but required that justice should be administered in his name, and that all persons of good moral character should be admitted to the Lord's supper, and their children to baptism. This was exceedingly offensive to the colonists, who treated the agents on their return with such coldness, that it is said to have hastened the death of Mr. Norton. He composed several works, which gave him considerable reputation in his time. The first Latin book ever written in this country came from him, and was an answer to a number of questions relating to church government, sent over

from Holland by Apollonius. He wrote a treatise against the Quakers, entitled "The Heart of New England rent by the Blasphemies of the Present Generation," which so exasperated the members of that sect, that after his death they represented to the king and parliament that "John Norton, chief priest in Boston, by the immediate power of the Lord, was smitten and died."

NORWALK. I. A township of Fairfield co., Conn., on Long Island sound, and on both sides of the mouth of Norwalk river, here crossed by a bridge, 45 m. N. E. from New York, and 81 m. S. W. from New Haven; pop. in 1860, 7,583. It is on the line of the New York and New Haven railroad, and is the S. terminus of the Danbury and Norwalk railroad. In 1860 it contained 2 banks, a foundery, various manufacturing establishments, 2 union schools with about 1,000 pupils, and 9 churches, viz.: 3 Baptist, 2 Congregational, 2 Episcopal, 2 Methodist, and 1 Roman Catholic. The town is largely engaged in manufactures, especially of felt, fur, and straw hats and hat bodies, felt cloth, shoes, clothing, earthen ware, and locks. Felt cloth was first successfully made in this town about 1836, and the manufacture has since been in a great measure fixed here by important patents. Several inventions for forming the bat, which constitutes the basis of the cloth, were patented prior to that time, but none of them was so well adapted to the purpose as the invention of John Arnold for crossing the fibres of the wool at right angles, patented in 1829, and improved in 1836. The "Union company" was organized in 1837, and has extensive mills and machinery, capable of turning out 1,000 yards a day. The Winnipauk mills are nearly as extensive, and can turn out 800 yards a day. The two establishments manufacture from 350,000 to 500,000 yards a year. In making cloth under the Arnold patent, the wool is sorted, picked, and carded in the usual manner (see FELT); but in forming the bat, a different plan is pursued. Two carding machines are used, one at the extremity of the endless moving apron, from which a thin layer of fibres is deposited upon the apron lengthwise, and another at the side of the apron from which another layer is carried by a comb carrier across the apron, and laid at right angles with the first. These layers are thus alternated until sufficient thickness is obtained. The bat is then removed from the apron, placed between two cloths, and passed under a hardener, which speedily felts the bat down to a thin flannel. The hardener is a heavy iron plate, to which a very rapid jigger motion is given. When the flannel comes out from under the hardener it is in pieces measuring about 36 yards in length, and from 8 to 9½ feet in width. It is then fulled up to the desired width and length, and dressed by substantially the same processes as are used in the making of thread goods. The cloths made here are handsomely finished, warm and impervious, and cheap, and are in demand for

cloaks, talmas, overcoats, and other heavy garments.—Norwalk was burned during the revolutionary war by a British force under Gen. Tryon, July 12, 1779. II. A city and the capital of Huron co., Ohio, on the line of the Cleveland and Toledo railroad, 110 m. N. from Columbus; pop. in 1859, about 4,000. It contains the county buildings and several educational institutions, among which are the Norwalk institute and a female seminary. It has a bank, a public library and reading room, 2 newspaper offices, 6 churches, 8 founderies, and steam flour and saw mills.

NORWAY (Norw. or Dan. *Norge*; Swed. *Norrige*; Ger. *Norwegen*; Fr. *Norvège*), a kingdom of northern Europe, occupying the western portion of the Scandinavian peninsula, and lying between lat. 58° 5' and 71° 11' N., and long. 5° 11' and 32° E. It is bounded N. by the Arctic ocean, E. by Russian Lapland and Sweden, S. by the Skager Rack, and W. by the North sea and the Atlantic ocean. Its length is about 1,080 m., and its greatest breadth 275 m. It is divided for political purposes into 5 stifts or provinces and 17 amts or districts, the area and population of which, according to the government returns for 1855, are as follows:

Divisions.	Area in sq. m.	Popu- lation.

It is united with Sweden under one sovereign, but according to the terms of the constitution is "free, independent, indivisible, and inalienable." The principal cities and towns are Christiania, the capital, Bergen, Drontheim, Stavanger, Drammen, Christiansand, and Frederikshald.—The coast is very much indented by arms of the sea, some of which are deep and form magnificent harbors, and from some the mountains rise perpendicularly to a vast height. The Christiania fiord, on which the capital is situated, is a long arm of the Cattegat. On the S. W. coasts are the Bukke and Bømmel fiords, and on the W. is the Drontheim fiord. The Lofoden islands, which belong to Norway, are separated from the mainland by a channel called the West fiord. There are numerous other islands along the coast, particularly toward the

N. and N. W. The principal rivers are the Tana and Alten in the N., flowing into the Arctic ocean, and the former forming part of the boundary on the side of Russian Lapland; the Salten and Namsen in the W., having their mouths in the Atlantic; and the Lauven, Drammen, and Glommen, which fall into the Skager Rack. The Loogen connects Lakes Losna and Miösen. The Klar rises in Norway, but has its mouth and the principal part of its course in Sweden. There are numerous lakes in all parts of the country, the largest being the Miösen, 40 m. N. from Christiania, 55 m. long and from 1 to 12 m. broad; it is formed by an expansion of the river Lougen, and flows into the Glommen through the Vermen. The surface is very mountainous, particularly in the N., but there are no well defined and regular ridges, the great Scandinavian chain, which runs, under the name of Kiolen and other appellations, N. and S. throughout the peninsula, consisting rather of a series of elevated plateaux from which rise mountain masses. The principal summits are Galdhoppigen, 8,785 feet above the sea, and Skagtölstind, 8,890 feet. The descent from these plateaux on the Swedish side is gradual, but toward the Atlantic across Norway it is abrupt and precipitous, though it stretches out far toward the sea, and in some places covers almost the entire width of the kingdom. The general character of the whole country in fact is extremely rugged. The valleys are short and abrupt. Precipices, cascades, and torrents are met with in every direction, and grand and picturesque scenery abounds. Among the most striking natural curiosities is the mountain of the Kilhorn in Nordland, a remarkable pyramidal peak, terminating with a long, sharp, spire-like summit, and having a large perforation about $\frac{1}{2}$ way up its side. The mountain of Hornelen, which forms the E. extremity of the island of Bremanger at the entrance of Vaags fiord, is an isolated mass from which rises a sharp-pointed peak inclined at an angle of 60° to the horizon, and appearing about to topple over upon the surrounding plain. Some of the mountain passes are extremely picturesque. The Vöring-foss and Rinkan-foss are cataracts, each 900 feet in perpendicular descent, and several of the rivers have falls of less height. Off the coast lies the Maelström, whose terrors have been so much exaggerated. (See *MAELSTRÖM*.) The geological formation is chiefly primitive and transition rocks. The most abundant is gneiss, alternating occasionally with granite, and abundantly intermixed with mica slate. Limestone, quartz, and hornblende are also found. In the S. districts there are many traces of volcanic action. The mountains are rich in iron, copper, silver, nickel, and cobalt. The soil is in general of poor quality. Only $\frac{1}{10}$ of the surface is thought to be arable, and not more than $\frac{1}{100}$ is actually under cultivation. The land is of a light sandy texture, which under the best cultivation could not yield heavy crops. There are however vast pasture lands

of very good quality.—The climate is healthy, and less severe than might be expected from the high latitude and elevation of surface, being considerably tempered by the sea and warm S. W. winds. Many of the western and northern gulfs and fiords are rarely or never frozen, while those on the S. are filled with ice. The mean temperature at Christiania is 48.1° F.; at Ullensvang, on the gulf of Hardanger, 44.9°; at Drontheim, 39.50°; at the Salten fiord, 48.1°; and at the North cape, 29.9°. The temperature is on the whole milder than that of any other region equally distant from the equator. Vegetation flourishes as far N. as lat. 70°, though in Siberia it ceases at about 60°. The weather is remarkably steady for the latitude. About $\frac{1}{10}$ of the surface is covered with perpetual snow; in other districts snow lies about 4 months in the year, beginning toward the end of November. In January and February the mercury ranges from 14° F. above to 15° below zero, and sometimes sinks to 81° below. In summer it rises occasionally to 108°, and the crops ripen 3 months after sowing. The principal crop is barley, which is cultivated as far N. as lat. 70°. Rye, oats, wheat (in favorable seasons and southern districts), potatoes, flax, hemp, a little tobacco, and apples, pears, cherries, and other fruits are also raised. There are large forests of valuable timber. The wolf and bear are the principal wild animals. Deer are now scarce. The lynx and wolverene are occasionally met with, and there are hares, wild fowl, and game in abundance. One of the most valuable domestic animals is the reindeer, which constitutes the main dependence of the inhabitants of the N. provinces. Cattle are reared in great numbers, but the breed is inferior; and the horses, though strong and sure-footed, are of small size. Ponies of a good breed are raised and exported. Sheep and goats are numerous. The rivers and lakes are abundantly stocked with many varieties of excellent fish, among which are trout and salmon, while the neighboring seas afford valuable fisheries of cod and herring.—The inhabitants of Norway are an ingenious, frugal, industrious, and honest race, surpassing in enterprise both Swedes and Danes. They are cold and reserved in manner, but kind and hospitable, simple in their habits, firm in purpose, and patriotic. They are among the best sailors in the world, large numbers of the population being engaged from early life in the coast fisheries, which are an excellent school for seamen, the navigation among the islands, shoals, and narrow channels being intricate and dangerous. The N. provinces are peopled chiefly by Laplanders, who live almost isolated from the rest of the inhabitants, and whose chief occupation is tending their reindeer herds. The industry of the more southerly provinces is devoted more to stock raising than tillage. Most of the land is the property of the cultivators. The large landholders are called proprietors; the smaller landholders, who exclusively farm their own

estates, are called bonders, and are among the most useful and active of the population. The system of agriculture is extremely rude, and the prejudice of the farmers against innovation precludes the hope of any speedy improvement. Under-drainage is never practised. The amount of grain of all kinds produced annually, exclusive of that retained for seed, is about 8,000,000 bushels, which is not sufficient for domestic consumption; and about half as much more, consisting almost wholly of rye and barley and valued at \$8,500,000, is annually imported from Denmark and Russia. The precariousness of the crops has led to the establishment of corn magazines where farmers may deposit their surplus produce, receiving interest for it at the rate of 12½ per cent. per annum, and in time of scarcity may borrow grain at the interest of 25 per cent. per annum. The pine and fir forests, which occur chiefly on the banks of the great rivers, give employment to great numbers of timber merchants; and their product, beside being converted into planks and beams, is invaluable for fuel in working the mines, no coal being found in the kingdom. The mines are not worked to their full profitable capacity, partly on account of the comparative scarcity of fuel, and partly of government restrictions. The yield of silver from the Kongsberg mines, which has been as great as \$312,000 a year, is now not more than \$100,000, the state, to which they belong, limiting the production for fear of exhausting them. The total produce of copper is from 400 to 500 tons. The Røraas copper mines have been worked for more than 200 years. The iron mines are very imperfectly worked, and do not yield more than 30,000 tons per annum, but the metal is of very superior quality. The value of the fisheries is about \$5,000,000 annually. Those of cod and *sey*, or Norway haddock, which are prosecuted chiefly in February and March along the N. W. coasts, employ about 3,500 boats of 8 tons and under; and that of herrings, the chief seat of which is between Bergen and Stavanger, yields 1,000,000 barrels annually. Lobsters are taken for the London market, two lines of packets being constantly employed during the season in their transportation. Mackerel are salted for winter consumption. An aggregate of 21,000 persons are employed exclusively in fisheries. The manufacturing industry is of very trifling importance, and consists chiefly in the production of cotton, woollens, linens, and silks for domestic use. There are not more than 6 or 8 cotton factories and 7 paper mills in the whole kingdom. The peasants supply nearly all their wants by their own labor. There are some distilleries, tobacco factories, and large salt works, beside various establishments connected with the mines.—The foreign commerce of Norway consists chiefly in the exchange of fish and timber for provisions and manufactured goods. The fish trade centres principally at Bergen, and comprises dried and salted cod,

cod liver oil, cod roes (sent to France and Spain to be used as bait for sardines), and herrings. About 600,000 barrels of the last are annually sent to Sweden, Denmark, and the Baltic ports; the codfish is taken principally by Russia, France, Spain, and Italy, and the oil by Germany and Holland. About 500,000 loads of timber are annually shipped to France, England, Denmark, Holland, and Belgium. Granite has recently been exported to Hamburg. The imports consist of wines and colonial produce, salt from Spain, and manufactured goods from Germany, France, Belgium, and England. The following table shows the commerce with foreign countries in 1855:

Countries.	Imports.	Exports.
Denmark.....	100	\$4,712,200
Great Britain.....	100	4,000,000
Hanse Towns.....	100	700,000
Sweden.....	100	2,001,000
South America.....	100	20,000
France.....	100	1,000,000
Netherlands.....	100	2,770,000
Prussia.....	100	2,111,000
Russia.....	100	70,000
United States.....	100	20,000
West Indies.....	100	20,000
Italy.....	100	21,000
Belgium.....	100	200,000
Spain.....	100	1,100,000
Portugal.....	100	20,000
Turkey.....	100	200,000
East Indies.....	100
Austria.....	100	10,000
Hanover and Oldenburg.....	100	210,000
Moscow.....	100	120,000
Total.....	\$17,200,000	\$20,100,000

In 1854 the imports amounted to \$14,288,400, and the exports to \$28,307,000. The merchant marine in 1856 consisted of 5,215 vessels, with an aggregate burden of 414,554 tons and an equipment of 28,560 men. In 1857, 10,928 vessels of 935,936 tons entered at the Norwegian ports, and 11,017 vessels of 946,339 tons cleared from the same. The foreign commerce is mostly in the hands of Hamburg merchants, and labors under many restrictions and considerable import duties. The trade with Great Britain is steadily increasing, while that with France and Holland does not seem to admit of much expansion. Considerable quantities of American cotton and tobacco find their way into the kingdom, but for the most part indirectly. The internal trade suffers from the want of good roads and the comparative thinness of the population. The highways however are being gradually improved, and there is now a railway from Christiania to Lake Mjösen. Other railways have been projected. Accounts are kept in specie dollars, called *species*, equal to \$1.00; marks or *orts*, \$0.21½; and *skilling*, ¼ of a cent. These coins are silver and copper, there being no gold currency. There is a national bank which issues notes.—Education is upon the whole well cared for. Every parish has its schoolmaster, paid partly by a small contribution from each pupil, and partly from the proceeds of a tax on householders. It is rare to find any one who cannot at least read and write. The towns have superior schools, and there is

a university at Christiania attended by about 600 students. The "Society of Public Good" maintains a number of public libraries in different parts of the kingdom, and there are many learned and scientific societies. Great pains is taken by the clergy with the religious education of their parishioners. The religion of the people is Lutheranism almost without exception, and until recently no other was tolerated. All Christian creeds, however, are now permitted to be publicly professed; and, after long debates in the *storting*, the Jews, too, have been lately admitted into the country. A small body of Quakers has existed at Stavanger in defiance of the laws ever since the beginning of the 19th century. There are a few Roman Catholics in Christiania, but Jesuits and members of other religious orders are rigorously excluded. The established church is governed by 5 bishops, the eldest of whom is primate. The right of presentation to sees and livings belongs to the king, the minister for ecclesiastical affairs, and the Norwegian council of state. The clergy are generally well educated, and their incomes average about \$1,000 per annum, which, taking into account the value of money in Norway, may be considered high. The press is perfectly free, and almost every important town has at least one newspaper. There are two or three scientific periodicals.—The government is a hereditary constitutional monarchy. The constitution was drawn up and adopted in 1814. The king of Sweden and Norway appoints for Norwegian affairs a council of 8 Norwegians, with whom rests the responsibility of all executive action. With their consent he may declare war, make peace, and conclude and abrogate treaties. The king must pass some months of every year in Norway, and on his accession to the throne must be crowned as king of Norway at Drontheim. He is required to profess the Evangelical Lutheran religion. The legislative power is exercised by the *storting*, or assembly of deputies, chosen by popular vote, and meeting triennially. Every male Norwegian 25 years of age and possessing \$150 worth of property has the right to vote. Representatives must be over 30 years of age and have been 10 years resident in the kingdom. The *storting* consists properly of only one chamber, but its members appoint ¼ of their number as an upper house, called the *lagthing*, while the rest are called the *adelsthing*. Both houses choose their own officers. The king cannot dissolve the *storting* until it has been 3 months in session; and, though he may veto any measure, his veto may be overruled by the action of 3 successive *stornings*. The *storting* makes and repeals laws; establishes imposts, taxes, and tariffs; authorizes loans, regulates the finances, votes appropriations, naturalizes foreigners, and examines documents relating to all public business, treaties, salaries, and pensions. There can be no domiciliary visits except in criminal cases, and no *ex post facto* laws. The army is not to be ordered out of the king-

dom without the consent of the *storting*, and no Swedish or other foreign troops shall enter Norway except to repel invasion; but a Swedish corps not exceeding 8,000 men may pass 6 weeks of each year in Norway off the purpose of exercising with the army of the latter kingdom. Norway preserves her own official language, bank, accounts, currency, and flag. The judiciary comprises courts of reconciliation in every parish, the arbitrators being chosen by the householders every 3 years; law courts sitting once a quarter in each of the 64 *sorenskriveries* into which the kingdom is divided; the *stiftsamt* in the chief town of each stift, composed of 3 judges with assessors; and the *høieste ret*, a court of last resort, in Christiania, which is composed of a president and 8 assessors. Capital punishment is not inflicted. The judges are liable in damages for their decisions. The budget voted by the *storting* for the 8 years ending June 30, 1860, shows a revenue of 13,888,500 specie dollars, and an expenditure of the same amount, or 4,622,500 specie dollars per annum. The principal items of the annual revenue were: customs, 2,550,000 specie dollars; excise on domestic brandy, 750,000; post office, 351,800; stamps, 75,000; imposts, 192,200; mines, 50,000. The chief items of expenditure were: civil list, 181,000; *storting*, 41,292; foreign relations, 98,108; army, 1,000,000; navy, 495,000; justice, 353,393; finances, 767,090; debt, 246,509; ministry of the interior and administration, 1,197,336. The public debt at the end of 1854 amounted to 4,884,300 specie dollars. The army consists of 14,824 men, viz.: infantry 11,924, cavalry 1,070, artillery 1,830. There is also a *landwehr* or militia of 9,160 men. The navy in 1858 consisted of 142 vessels, mounting in all about 450 guns. Of these, 8 were frigates, 5 corvettes, and 125 gun boats.—The history of Norway prior to the 7th century rests upon tradition. The descendants of Odin are represented to have been the first kings, the earliest whose name has been transmitted to us being Scæming. Nor, the scion of an ancient Finnish family, established himself upon the site of modern Drontheim early in the 4th century, and subjugated the neighboring territory. Authentic history begins with Harald Harfager or the Fair-Haired, who subdued the petty kings or jarls of Norway, and united the tribes as a nation (A. D. 863–988). In his conquest he is said to have been animated by the love of Gyda, daughter of the jarl of Hardaland, who vowed not to wed him until he had subjugated the whole country. His victories induced many of the defeated princes to emigrate, and hence began the famous maritime and piratical adventures of the Northmen. (See *NORTHMEN*.) His son Haco the Good, who had been educated in England at the court of Athelstan, introduced Christianity; but the old religion was not completely eradicated until 8 centuries later. Olaf or Olans I., who came to the throne in 995 after a successful revolt, brought the sword to the aid of the gospel, de-

stroyed the pagan temples, and laid the foundations of Drontheim. He was killed in battle with the Danes, and for 15 years following Norway was a prey to Swedish and Danish marauders. In 1015 Olaf II. (St. Olaf) determined to complete the work of his predecessor, and persecuted the pagans, though with less cruelty than Olaf I. In 1028 Canute the Great of Denmark and England landed in Norway, drove Olaf out of the kingdom, and was elected king. Olaf subsequently returned with an army, and was defeated and slain at Stikklestad in 1080. His body, according to the legend, having been found incorrupt several years afterward, was removed to Drontheim, and the people made pilgrimages to his tomb until the reformation. Canute deputed his son Sweyn to govern Norway, but after the death of his father Sweyn was driven out by Magnus I., the son of St. Olaf. Harald III., surnamed Hardrada from his severe discipline (1047–1066), invaded England, and, after capturing York, was slain in battle by the English king Harold II. at Stamford Bridge, in Yorkshire, Sept. 25, 1066. His grandson Magnus III. (1087–1103) conquered the isle of Man, the Shetlands, Orkneys, and Hebrides, and invaded Ireland, where he was killed in battle. His son Sigurd I., the great hero of Scandinavian song, is famous for various exploits against the Moors in Portugal and at sea, and for a pilgrimage to Jerusalem, where he offered his arms to Baldwin, and with him reduced and plundered Sidon. His death (1130) was followed by 84 years of civil war, interrupted only temporarily by the efforts of the English cardinal Nicholas Breakspear, afterward Pope Adrian IV., who came to establish an archbishopric at Drontheim, and instituted many excellent reforms. Order was restored by Sverrer in 1184. His illegitimate son Haco IV. was succeeded by Guttorm and Haco V. (called by some of the chroniclers Haco IV.), who subjugated Iceland (1261), and died in the Orkneys after losing a battle at the mouth of the Clyde (1263). The national prosperity of Norway declined from this epoch. Wars with Denmark exhausted the people. A monopoly of trade in the hands of merchants of the Hanseatic league checked the national industry; and a plague, called the black death, which broke out in 1348, ravaged the kingdom to an unparalleled extent, destroying $\frac{1}{3}$ of the population. It raged for more than 2 years. The country fell into a decay which was not overcome for centuries. Magnus Lagabæster (law reformer) reigned from 1263 to 1280, and was succeeded by his son Eric II. After the death of Haco VII. in 1319 two Swedish kings obtained the throne successively, Magnus VIII. of Norway and II. of Sweden, and Haco VIII. of Norway, reckoned by some as the 6th of the name. The kingdom lost its nationality. A province first of Sweden, and afterward of Denmark, the country was robbed even of its proper language, which became thenceforth a corrupt mixture of those of its neighbors. Haco

VIII. married the daughter of Waldemar of Denmark, and died in 1380. The crown descended to his infant son, Olaf III. of Denmark, from which period down to the year 1814 the two countries were united. Margaret of Denmark, the "Semiramis of the North," succeeded her son Olaf III., and, having reduced Sweden, framed the "Union of Calmar" (1397), the object of which was to unite the three crowns upon one head. With this view it was stipulated that the subjects of each country should have equal rights under the common sovereign, and should be governed by their own laws. From this period, and in violation of the treaty, the Norwegians lost all their independence. The nobles, wholly supplanted by Danish immigrants, were amalgamated with the peasants, impoverished, exiled, or massacred. The union of Calmar was severed by Gustavus Vasa of Sweden in 1523; and during nearly two subsequent centuries Norway was scarcely more than a province of Denmark. In the reign of Christian I. the Shetland and Orkney islands were transferred to Scotland as part of the dowry (in mortgage of money) of Christian's daughter on her marriage with James III. of Scotland. They were never redeemed. Christian died in 1481. The reformation reached Norway first in 1536. Christian IV. (1588-1648) was more popular in Norway than any other Danish king. He visited Norway more than 50 times; founded Christiania (1624) and Christiansand (1643); and instituted a code of laws, many of which are still in force. After this reign Norway was treated as a conquered province rather than as a joint kingdom; and it was not until the early years of the present century that a brighter day began to dawn. Frederic VI. founded the university of Christiania (1811), and was endeared to the Norwegians by much care of their concerns. Meanwhile the Swedish government had entered into the coalition against Napoleon (April 8, 1812); and by convention with Russia the possession of Norway was guaranteed to Sweden. England also entered into this guaranty, and the newly elected crown prince of Sweden, Bernadotte, according to engagements, took command of the allied forces in Germany. After the battle of Leipsic (Oct. 16-19, 1813), the crown prince led the Swedish contingent into Holstein, with a view to compel the Danish government to cede Norway. A singular system of spoliation prevailed. Napoleon had signed away to Russia the Swedish province of Finland, which did not belong to him. Russia now indemnified Sweden by a present of Norway, to which she had no title; and England offered to Denmark an equivalent in lower Saxony, which was in the possession of France. After the fall of Lübeck and some bloody actions in Holstein, the Danes were forced to the peace of Kiel (Jan. 14, 1814); and Norway was acknowledged as a dominion of Charles XIII. of Sweden. The people of Norway heard of this treaty with great in-

dignation. The Danish crown prince, Christian, perceiving the popular demonstration, hastened to Norway, convoked a national diet, and met them at Eidsvold, near Christiania. They offered him the crown of Norway in independent sovereignty, which he accepted, and with it a constitution hastily drawn up on the spot. This was in May, 1814. In July the Swedish crown prince, at the head of an army, invaded Norway by way of Frederikshald. A British fleet appeared off the coast, and blockaded the ports. Resistance was obviously a waste of life and property, and after a few unimportant actions the country submitted. The Danish prince abdicated his new throne; and on Aug. 14 an armistice and a convention were signed at Moss, uniting Norway and Sweden. The Norwegians obtained far better terms than had been designed by the allies originally. The constitution, previously accepted by Christian, was now accepted by Charles XIII. A few disturbances in the northern districts were speedily quelled; and at Christiania the storting formally ratified the union (Oct. 20, 1814). The constitution of Eidsvold, with few alterations, was accepted by the king, Nov. 4, 1814. On the death of Charles XIII., Bernadotte ascended the throne (1818) as Charles XIV. John. He made many unavailing attempts to reduce the country to closer submission to royal authority; and in his great desire to effect alterations of the constitution, he tried every means in vain to win over a majority of the Norwegian storting. He endeavored twice to obtain, in place of the suspending veto, an absolute one. On other occasions also he was forced to yield to the legislative will. In 1815 the storting passed a resolution to abolish titles of nobility, a measure which the king refused to approve. The next two storthings passed the same resolution, notwithstanding an appeal of the king in person, and a strong military demonstration on the Swedish frontier; and the royal veto was thus rendered constitutionally null. Some years later the storting resolved that the people of Norway should be styled citizens of that kingdom. Rarely indeed has a political assembly shown more jealousy of executive privileges. The late King Oscar, who succeeded his father March 8, 1844, was more conciliatory in his policy, and soon obtained a greater degree of confidence. Soon after his accession he gave the Norwegians a separate national flag, which his father had refused. In 1847 he established a Norwegian order of merit, that of St. Olaf. The general feeling of anxiety concerning Russian encroachments brought about an alliance, in Nov. 1855, between Norway and Sweden, England, and France. By this treaty the two Scandinavian powers, in exchange for a promise never to cede or sell territory to Russia or to any power without the consent of England and France, received a guaranty of future territorial integrity under protection of the last named powers. In 1857 King Oscar, in consequence

of bad health, transmitted the government to his son Charles Louis Eugene as regent, who on the death of his father, July 8, 1859, ascended the throne with the title of Charles XV. Soon after the opening of the parliament or *storting* by the new king (Oct. 6), the old antagonism between the democratic spirit of the Norwegians and the aristocratic character of the Swedes manifested itself in the rejection of the request of the king to reduce the time of his annual residence from 9 months, at which it is fixed by the constitution, to 6 months, and in withdrawing from him (Dec. 12, 1859) the right of appointing a governor of Norway, that office to be filled in future by a minister of state. A motion, however, to make the meetings of the *storting* annual instead of triennial, was rejected by that body (Feb. 28, 1860); but the excessive spirit of independence shown in other respects, particularly in regard to the appointment of governor, has given rise to considerable discussion in Sweden, and tends to complicate the relations between the two countries. The king was crowned at the ancient cathedral of Drontheim in Aug. 1860.

NORWAY, LANGUAGE AND LITERATURE OF. The *Norræna Tungu*, now known as the Icelandic, both because it is still spoken in its purity in Iceland, and because nearly all its extant literature is the work of Icelanders, was the common language, with only trifling variations of dialect, of Denmark, Norway, and Sweden down to the middle of the 18th century. Norway, in consequence of her remote situation, retained the old tongue longer than either of her sister kingdoms. The few mediæval Norwegian documents, consisting chiefly of letters and codes of laws, do not exhibit any important grammatical changes until about the time of the annexation of Norway to Denmark toward the close of the 14th century. But from this period the influence of the governing nation was so great that a rapid transformation took place, and soon after the beginning of the 16th century the written language and the speech of the higher classes became identical with those of Denmark. Outside of the large towns and among the peasants, however, the Danish has never been the spoken tongue, but the old *Norræna* has been corrupted into a number of dialects, diverging more or less in their structure from their ancient original. From these dialects some patriotic Norwegian philologists, since the separation from Denmark, have attempted to construct a national tongue; but beyond the compilation of a grammar and dictionary, and the publication of a small newspaper and a few pamphlets, their efforts have met with but little success, owing in part to the great differences in the dialects themselves. The Danish is still the language of society, of the pulpit, and the press, and continues to be taught in the schools. The Norwegian dialects, according to Aasen, may be classified in three divisions, corresponding to the natural divisions of the country:

the *Nordenfjeldsk* group, comprising those spoken in the province of Drontheim and the extreme northern provinces; the *Vestenfjeldsk* group, or those spoken west of the mountains in Bergen and the western portion of Christiansand; and the *Søndenfjeldsk* group, including those spoken in southern Norway, or to the east of the mountains. Of these three divisions, the second approaches the nearest to the Icelandic, the isolated localities and little frequented valleys along the western firds having been favorable to the preservation of the ancient speech; while the last named, lying nearer to Christiania, has been the most largely influenced by the Danish. All of them possess some peculiarities in common, which distinguish them from the written speech. The old diphthongs, *au*, *ei*, *øy*, are retained; the hard consonants *k*, *t*, and *p* are placed after as well as before vowels; a distinction is made between the terminations in *a* (*ar*) and those in *e* (*er*); although the genitive form of the nouns is generally lost, the old dative is often retained; the distinction between the masculine and feminine genders of substantives, nearly or quite lost in Danish and Swedish, is still marked; and the definite article (Icelandic *hin*, *hinn*, *hitt*) requires the substantive which follows it to take the definite termination also, as is still the case in Swedish but not in Danish.—Norway, although she has given to Denmark such writers as Holberg and Storm, and to Germany such scholars as Steffens and Lassen, cannot be said to have had a distinct literature until after her political union with Sweden. Before that date the writings of her poets, historians, and naturalists properly form a part of Danish literature. The foundation of the university of Christiania in 1811, and the complete establishment of political independence in 1814, gave an energetic impulse to the national spirit, and with these two events the records of Norwegian literature begin. The organization of an independent government in a land which for more than 4 centuries had occupied the position of a province, naturally enough turned the minds of men first of all to the discussion of the principles of political economy and jurisprudence. The literature of Norway for 10 or 20 years after the union consisted chiefly of political essays, legal tracts, treatises on agriculture and manufactures, and text books for popular instruction. Among the noted publicists and economical writers are O. M. Falsen (1782–1830) and Sverdrup (born 1778), both of whom were prominent members of the constitutional convention of Eidswoold; Ræder, Mariboe, Petersen, Platon, Daa, and Blom; and F. Monrad has lately given to the public a large work on the history of political science. Keyser and Munch have critically and philologically edited the ancient Norwegian codes of law; Schweigaard has written commentaries upon the present jurisprudence; Aubert and Ræder have treated of the principle of jury trial; and other juridical writers of eminence are P. O. Lassen,

Smidt, Bull, and Brandt. Beside the numerous and careful *Statistiske Tabeller* annually issued by the government, J. E. Kraft (born 1784) published a topographical and statistical description of the kingdom (6 vols., 1820-'35); Tvethe issued his *Norges Statistik* in 1848; and in the department of social statistics the treatises of Ellert Sundt are well known. In physics several Norwegians have achieved a European reputation. The discoveries of Christopher Hansteen (born 1784), which were made known in 1819, mark the commencement of a new period in the study of the phenomena of terrestrial magnetism. In the *Gæa Norvegica* of B. M. Keilhau (1797-1858), in which the author published his geognostic map of Norway, and in the account of his journey to Finmark and Spitzbergen, large additions were made to geological science. Theodor Kjernulf, a writer of equal ability, has succeeded Keilhau in the professorship of geology at the national university. The explorations of Jens Esmark (born 1768) among the Norwegian mountains resulted, according to Forbes, in some novel and well founded theories on the formation and structure of glaciers; and J. C. Hørbye has treated (1857) with great clearness the subject of the erosion of mountains. The leading botanists have been Christen Smith (1785-1816), whose travels in the Congo region of Africa were first published by the British government; Sommerfeldt, who, beside a treatise on the cryptogamous plants of Norway, gave to the world in 1826 a large supplement to Wahlenberg's "Laplandic Flora;" and Blytt, the first part of whose *Norsk Flora* appeared in 1847. In zoology the splendid work of Michael Sara, a Norwegian *Fauna Litoralis*, now in process of publication, is widely known. Halvor Rasch has also written several small but noteworthy treatises on the same subject. The mathematical writings of N. H. Abel (1802-1829), whose early death was a severe loss to science, have been translated into French; other authors of distinction in the same branch are B. Holmboe and O. J. Broch. In 1848 Danielsson and Boeck published, in Danish at Christiania and in French at Paris, the important results of their investigations into that singular disease, *spedalskhed* or elephantiasis, which is prevalent in Norway and Iceland; and during the present year (1860) their work has been followed by another essay of great value by Bidenkap. Boeck was the first to advocate inoculation in syphilitic diseases; F. Holst (born 1791), a physician and statistician, greatly contributed by his treatises on the subject to the improvement of the Norwegian hospitals and prisons; and Skjelderup published one or two volumes of interest to the medical student. The schism produced by the labors and writings of Hauge (1771-1824), and the freedom of religious worship secured by the Norwegian constitution, have tended to produce many theological writers of ability. Among the most noted are W. A. Wexel, whose writings are chiefly exegetical; S. J. Steensen (died

1835), whose numerous works are principally of a popular character; and K. P. Caspari, born at Dessau in 1814, but for many years attached to the university of Christiania, whose commentary on Isaiah and whose learned monograph *Ueber Micha* have been widely circulated both in Norway and Germany. Metaphysics have been little cultivated, and the only authors of note are M. J. Monrad and O. Heiberg. The history, philology, and antiquities of Norway have been studied with unflinching zeal. Jacob Aall (1778-1824) translated the voluminous chronicles of Snorro Sturleson, beside leaving to posterity an interesting record of his own times in his *Erindringer* or memoirs; A. Faye published a history of Norway in 1844; Rudolph Keyser followed up his account of the religion of the ancient Northmen (translated by Pennock, New York, 1854) with a more extensive work on the history of the Norwegian church during the Catholic period; O. A. Lange and O. R. Unger are editing a *Diplomatarium Norvegicum*; and the ancient remains scattered throughout the country have been illustrated by Nicolaysen and others. But by far the most important national historical work is *Det norske Folks Historie*, by Peter Andreas Munch (born 1810), of which the 4 stout volumes already issued come down to the close of the 14th century. In 1847, by the publication of Munch's edition of the elder Edda, and a grammar and chrestomathy of the old language, was founded the Norwegian school of philology, whose national zeal has led to many warm disputes among the Scandinavian philologists. Its members, from the outset, boldly asserted that the pure Norræna was never spoken anywhere on the mainland but in Norway; that the old Swedish and old Danish were distinct tongues, and that, therefore, the language of the Eddas and Sagas should be styled Old Norwegian (*Old-norsk*), and not Old Northern (*Forn-nordisk*, *Old-nordisk*), or Icelandic, as it is called in Sweden and Denmark. They did not confine their claims to the language alone, but extended them to the literature. All those mythological, historical, poetical, and romantic writings which were produced by the pens of the Icelandic skalds and sagamen in the golden age of the insular republic were decided to be not Icelandic but old Norwegian, on the ground that Iceland was originally peopled by colonists from Norway. The Icelanders, who saw themselves thus deprived at a blow of what constitutes their chief national glory, and the Danes and Swedes, who were thus shut out from all share in that ancient language which their scholars have so ably illustrated, did not hesitate to protest against the assumptions of the Norwegian school. Although the peculiar doctrines of the Christiania writers have met with but little support outside of Norway, yet their many able editorial and grammatical labors deserve the gratitude of all those interested in the study of the Icelandic. The works of P. A. Munch, O. R. Unger, and R. Keyser, the lead-

ers in this new philological movement, comprise, among others, a treatise on the oldest form of runic writing, a Gothic and an Old Swedish grammar, and editions of *Fagr-skinna* (1847), *Alexandurs Saga* (1848), *Saga Olafs hins Helga* (1849), *Strengleikur* (1850), *Aslak Bolts Jordbog* (1852), *Stjórn* (1858), *Saga Olafs Tryggvasonar* (1858), and of the important *Saga Didriks af Bern*. Ivar Aasen has published a *Grammatik over det Norske Folkesproget* (1848) and an *Ordbog* (1850). O. A. Holmboe (born 1796) has bestowed an important contribution upon comparative philology by his "Comparative Lexicon of several of the Indo-European Tongues" (Vienna, 1852), and by other works. The dialects of the Laplanders who live under the Norwegian crown have been laboriously studied by N. J. O. V. Stockfeth (born 1787), a distinguished missionary, and by I. A. Friis, whose *Lappisk Sproglaere* was issued in 1852. In classical philology the chief laborer is L. O. M. Aubert. The poems and dramas of H. A. Bjerregaard (1792-1842) are national in spirit, but lack originality and brilliancy. Henrik Arnold Wergeland (1808-'45) was for a long time the favorite poet of the Norwegians, and a complete collection of his works in 9 volumes has just been published. J. S. Welhaven (born 1807) has published a great number of lyrics and several historical dramas, principally founded on national subjects. Andreas Munch (born 1811), a cousin of the historian, by his poetical and dramatic productions has rendered himself the most popular of the living poets. His *Digte* (1848), *Nye Digte* (1850), *Reisebilleder* (1851), and *Sorg og Trøst*, are his chief works. M. O. Hansen (1794-1842) produced a multitude of poems and romances, beside several works on other subjects. P. O. Asbjørnsen and J. Moe, in their *Folkeeventyr* and *Huldreroseventyr* (2d ed. 1859), have collected the popular tales which have been orally preserved by the Norwegian peasants for many generations; and M. B. Landstad and Sophus Bugge have each edited collections of the old popular ballads. Among the younger poets, the best known are J. Moe (the author of *Gammelt og Nyt*, or "Old and New," a collection of poetry and novels, published recently), Kjerulf, Schiwe, Bentsen, Schwach, and Sivertsen, and the dramatic writers O. P. Riis, H. Ibsen, and R. Olsen. Two novelists have above all others recently attracted attention; these are Bjørnsterne Bjørnsen, whose *Synndøes Solbakken*, a tale of Norwegian peasant life, has met with great success; and Mrs. Camilla Collet, whose novel *Amtmandens Døttre* (1854-'5) has gone through several editions. The leading scientific journals of Norway are the *Journal for Videnskaberne*, edited by Hansteen, Lundh, and Maschman since 1828, and the medical *Journal for Lægevidenskaberne*. There were 52 daily and weekly journals published in Norway at the end of 1859, of which 12 were issued at Christiania. The increase of the literature is shown by the fact

that the number of works published for the 7 years before 1834 averaged 76 annually, in the following 7 years 91, in the next 7 years 133, and, in the 7 years preceding 1854, 146. Between 1848 and 1854 there were 1,028 works published, 791 in Christiania, 100 in Bergen, and the remainder in other towns, of which 870 were original, 139 translations, and 14 new editions. A literal reprint, for the first time exact and complete, of the well known *Platetjærbok* (*Codes Flatoriensis*), containing all sorts of historical and legendary lore, in prose and verse, formal and episodical, concerning Norway, Iceland, and the whole north, England included, is in course of publication with the assistance of the Norwegian government, the first part of which appeared in Christiania in 1859. The publication of a posthumous work by J. E. Kraft, entitled *Norsk Forfatter Lexikon*, a complete Norwegian bibliography, was commenced in 1860 under the editorship of O. A. Lange.

NORWICH, a semi-capital of New London co., Conn., at the head of navigation on the Thames river, 18 m. N. from New London, 38 m. S. E. from Hartford, and 58 m. N. E. from New Haven; lat. 41° 33' N., long. 72° 7' W.; pop. in 1860, 14,052. It is divided into 8 parts, Norwich city, or Chelsea Landing, the Town, and Greenvile. The first is handsomely built and picturesquely situated on a steep hill facing the S., and lying between the Yantic and Shetucket rivers, whose junction forms the Thames, and which afford extensive and valuable water power. The houses are generally white, and, rising in terraces one above the other, can be seen from a considerable distance down the river, whose elevated banks lend additional attraction to the view. The Town lies to the N. W. in a pleasant valley surrounded by hills; and Greenvile, which contains numerous manufacturing establishments, is N. E. of the city. In 1860 there were 85 manufacturing establishments, employing a capital of \$2,655,200, and producing annually \$4,152,600 worth of goods. The manufactures consist principally of cottons. Woollens, paper, and machinery are also largely produced. Beside the county offices there were 6 banks, 2 savings banks, 4 insurance companies, 2 weekly newspapers and one daily, and 17 churches, of which 8 were Baptist, 3 Congregational, 3 Episcopal, 3 Methodist, 1 Roman Catholic, and 1 Universalist. There were 39 public schools, 5 private schools, and a free academy. The public schools and academy contained 2,866 pupils, and the sum of \$15,824 was raised from taxation and other public sources for their support. The free academy was built and endowed by the private subscription of \$110,000 by residents of the town, and is open for a full academical education to all the children of the town, free of expense to them, and without regard to sex or condition. At the falls of the Yantic, about 1 m. from its entrance into the Thames, the river is compressed into a narrow

channel, and rushes over a rocky bed having a perpendicular descent of about 50 feet. Yanticville in the vicinity is an active manufacturing village. At Greenville is the paper mill of the Chelsea manufacturing company, one of the largest in the world. There is extensive railroad communication by means of the Norwich and Worcester, and New London, Willimantic, and Palmer railroads, and regular steamboat lines connect with New York.—Norwich was settled in 1659. In that year Uncas and his two sons made a formal deed of the site of the old town, 9 m. square, to Major John Mason and 84 other proprietors, and received from the company £70 as a compensation. Its settlement was begun by Major Mason and the Rev. James Fitch, who, with a part of his congregation, removed from Saybrook.

NORWICH (anc. *Venta Icenorum*), a city, municipal and parliamentary borough, and the capital of the county of Norfolk, England, situated on the Wensum river, 98 m. N. E. from London; pop. in 1851, 68,706. It is a place of great antiquity, and was already a flourishing town in the time of Edward the Confessor. It is still surrounded by fragments of its ancient walls, which were flanked with towers and entered by 12 gates. The streets are narrow and mostly unpaved, and the houses are built of brick with rude pointed gables; but the market place is one of the largest in the kingdom. The celebrated cathedral of Norwich, founded in 1094, and chiefly of Norman architecture, is a cruciform structure, with a tower (restored in 1858) and spire rising from the intersection of the nave and transepts to the height of 815 feet. There are 40 other churches, and 22 dissenting chapels. Of the churches the most remarkable are St. Peter's Mancroft (where Sir Thomas Browne was buried), St. Andrew's (built in 1506), St. Clement's, St. George's, Colgate, St. Giles's, St. Michael's, Coslany, St. Gregory's, St. John's Maddermarket, St. Lawrence's, and St. Stephen's, all built before the reformation with the exception of the last. Among the other public buildings of importance are the castle, a feudal structure of Norman origin, and the guildhall. Norwich is the most ancient manufacturing town in the kingdom, and has been noted for its woollen fabrics since the reign of Henry I., when a colony of Flemings settled there, and obtained long wool spun in the village of Worsted, 9 m. distant, whence the produce took its name. The leading manufactures are shawls, crapes, bombazines, muslin de laine, damasks, camlets, gros de Naples, and bandanna handkerchiefs. Norwich sends 2 members to parliament.

NOSE, the organ of the sense of smell in vertebrated animals, and in the 8 highest classes connected with the respiratory function. Of the 14 bones which enter into the composition of the cavities of the nose in man, the principal are the nasal, attached more or less perpendicularly to the frontal bone above and to the superior maxillary on the sides; in the lower

orders these bones become more horizontal and more developed, as the face and animal propensities predominate over the cranium and the intellect. The nasal cavities, bounded in front by these bones, and separated into two by the vomer, open widely anteriorly to the external air and posteriorly into the back part of the mouth; the upper wall is pierced by numerous foramina, through which enter the filaments of the olfactory or nerve of smell; the lower wall forms the bony roof of the mouth, and is nearly horizontal; the outer wall is divided into the superior, middle, and inferior meatuses by the turbinated bones, into the 1st of which open the posterior ethmoidal and sphenoidal sinuses, into the 2d (much larger) the frontal and anterior ethmoidal sinuses and the great cavity of the antrum, and into the 3d the duct of the nasal canal which conveys the tears from the eyes to the nose; from the last also the Eustachian tube, by which the tympanic cavity of the ear communicates with the throat, may be most easily entered, as is frequently necessary in aural surgery; the *septum* or inner wall is rarely vertical, but generally leans to one side or the other. The suture of the nasal bones in man remains ununited generally until very late in life, in this differing from the condition in the highest apes, in which they are very early consolidated into a single bone with hardly a trace of suture; their inner border is also elevated, so that the depressed nose of the negro has never the flatness of that of the gorilla and chimpanzees. The external prominent part of the nose, which gives the character to the feature, is composed of several cartilages, connected to the bones and to each other by strong fibrous tissue, sufficiently firm to preserve the shape of the organ, and so elastic and flexible as to permit the expansion and contraction of the nostrils in respiration; at the tip of most noses, on the median line, may be felt a fossa or depression bounded on each side by the lateral cartilages, which, with the absence of rigidity, some ethnologists have made characteristic of certain human races, like the Malay and negro. The varying expression given to the face by the movements of the nose depends on the action of its muscles, attached to the cartilages, skin, and upper lip; most of the expressions arising from these movements are disagreeable, indicating either contempt, anger, fear, or pain. The openings of the nose are provided with stiff curved hairs, which prevent the entrance of many particles floating in the air. The lining mucous membrane, called the Schneiderian or pituitary, extends into the antrum and the frontal and other sinuses; it is for the most part well supplied with vessels, especially veins, communicating with those within the skull, so that bleeding at the nose is a common and beneficial termination of cerebral congestion from any cause; it presents also numerous glandular follicles, whose secretion is well known, and receives the filaments of the nerves of smell and of

common sensation. The soft olfactory nerves or nerves of smell arise from the anterior lobes of the cerebral hemispheres, and their bulbs rest on the cribriform plate of the ethmoid bone, which the branches pierce to the number of 15 or 20 on each side, and then running under the mucous membrane are distributed principally to the septum and outer wall of the nose, communicating with filaments from the sympathetic cerebral ganglia. Beside its special sense of smell, the nose has its ordinary sensation like other parts of the face, depending on filaments of the trifacial or 5th pair of cerebral nerves; that these two sensations are distinct may be experienced every time we have a catarrh in the head, in which, though the sense of smell, or the perception of odor and flavor (the latter constituting a great part of what is generally called taste), may be greatly impaired, the common sensation, or the susceptibility to the action of snuff and other irritants, is not at all diminished. The motor nerves of the nasal muscles are branches of the facial or 7th pair of cerebral nerves; the arteries are derived from the ophthalmic, internal maxillary, and facial branches of the carotids. The nose is the proper channel through which in most vertebrates air is drawn into and expelled from the lungs; in man the mouth also is used in respiration, but with what discomfort is known to all who are in the habit of sleeping with the mouth open; while the mouth soon becomes dry from the passage of air over its membrane, no such inconvenience is experienced from breathing through the nose for any length of time, in the condition of health; dust and other foreign particles, which get by the hairs of the nostrils, are caught in the irregularities of the nasal passages and arrested by the moisture of the membrane, so that we can breathe for some time in a cloud of dust without any passing into the lungs; the horse, and many other animals naturally exposed to dust, have the nasal passages better provided than those of man for the protection of the lungs; the moustaches also are natural and efficient appendages for the comfort of the air passages. The acute sensibility of the nose detects any impurity in the respired air, whether odorous or irritating, and warns man and animals of the presence of danger, or by the act of sneezing removes any injurious particles which may accidentally have entered the nose.—The nose forms one of the characteristic features of the human face, and by physiognomists has been regarded as a faithful index of character. The sense of smell is less developed than that of sight in man, and in comparison with that of some other animals is very feeble, and the more so in proportion to the elevation of the race in the scale of civilization; the blind have a more acute sense of smell to compensate for the deficiency of sight; the Mongolian, the negro, and the American Indian have a greater development of the internal cavities of the nose than the white races. In man only does the

nose project beyond the level of the upper jaw, the opening of the nostrils being horizontal and downward; even in the highest apes this feature is flat, and the nasal orifice vertical and forward. The ethnological characters derived from the shape of the nose are given in the articles on the different races, and in *ETHNOLOGY*. In fishes, breathing by gills, there is no communication between the nose and the mouth or throat, except in the myxinoids; in batrachians and reptiles, all of which, in the adult state, breathe more or less by lungs, the nose and mouth communicate, by a short passage as in the frog, or by a long one as in the crocodile; in birds the nostrils open on the back of the bill, generally nearest the base, and frequently covered by bristly feathers to prevent the entrance of foreign bodies, and they communicate with the mouth behind; in mammals only are found the sinuses and cellular cavities in the frontal, sphenoid, ethmoid, and superior maxillary bones, larger in some than in others; the nasal cartilages are often widely different from those of man, as may be seen in the movable snout of the mole and hog, and in the proboscis of the tapir and elephant, which are only modified and largely developed noses; in cetaceans the nasal openings are on the top of the head, constituting the blow-holes.—There are many congenital defects in which the nose is concerned. It may be almost entirely deficient, partially developed, closed in front, or fissured below; the septum may be distorted or absent; or the organ may be monstrously developed, as noticed under *CYCLOPSIA*. The skin of the nose is subject to cutaneous eruptions; the numerous small veins may be dilated, giving a red color to the tip, which, from the disturbance and retardation of a naturally slow circulation, is very difficult to remove. In common colds the mucous membrane is gorged with blood, and often so thickened as to interfere with respiration through the nose, and even to close the posterior passage to the throat. Abscesses, chronic thickening, deep ulcerations, ozæna, lupus, polypus, and cancer are common in this organ, and can only be alluded to here. Some of the greatest triumphs of modern reparative surgery may be found in the history of rhinoplastic operations, in which skin from the forehead or cheek has been dissected up, partially twisted, and caused to unite over the nasal cavities laid bare by accident or disease. (See *AUTOPLASTY*.)

NOSTRADAMUS, MICHEL DE, a French physician and astrologer, born of Jewish parents in St. Rémy, Provence, Dec. 14, 1538, died in Salon, July 2, 1566. He studied the classics and philosophy at Avignon, and medicine at Montpellier, and afterward travelled in the south of France for 5 years. He then returned to Montpellier, took the degree of M.D. in his 27th year, and again set out on his travels. He was very successful in curing the plague in Provence, by means of a powder which he invented. About the year 1547 he began to believe him-

self inspired with prophetic powers. He first wrote his predictions in prose in very enigmatical style, but afterward changed the form to verse, and in 1555 published in Lyons 4 "Centuries" of quatrains, dedicated to his son, an infant. Having increased these to the number of 1,000, he published a new edition in 1558 dedicated to King Henry II., whose remarkable death in a tournament the following year was found to be foretold therein, which greatly increased his fame. He became very celebrated throughout France, was made physician in ordinary to Charles IX., and was consulted by all classes of persons for diseases and for the foretelling of fortunes and public events, as plagues, fires, floods, victories, and the death of kings. By some he was regarded as a charlatan, by others as having intercourse with the devil, and by others as a true prophet. He was said to have predicted the death of Charles I. of England and of Louis XVI., and the elevation of Napoleon to the empire of France. He was an intimate friend of Scaliger. Nostadamus is said to have been the first to publish almanacs containing predictions of the weather, &c., and was the author of several other works now forgotten. His "Centuries" have been often reprinted and translated. The best edition is that of Lyons (8vo., 1668).—His son César was the author of *Histoire et chronique de Provence* (Lyons, 1614); and his brother Jean wrote *Vies des plus célèbres et anciens poëtes Provençaux* (Lyons, 1575).

NOTABLES, ASSEMBLY OF. See FRANCE.

NOTARY PUBLIC, an officer appointed to draw up and attest deeds and contracts, and perform other similar functions. The name and office of notary are of Roman origin. The *notarii*, so called from the *nota* or short-hand characters in which they minuted the instruments which they drew, had not a public character. They were mere scribes, it seems, whose calling it was to write out at their tables in the forum the agreements of those who addressed themselves to them. The writings thus composed were completed by the signatures of the parties. Unless these signatures were attested by witnesses or verified by proof of the handwriting, the instruments could have no authority in the courts. But it was possible to render them valid, and thus to escape the annoyance of these modes of confirmation, by a declaration of their tenor before a magistrate and by registration of them in the public records, *apud acta*. Like the *notarii*, but more like the notaries public of the present day, were the *tabelliones forenses*. They drew up legal documents and papers, and various kinds of declarations and statements to be sent to the courts of law or presented to different civil authorities. The *tabelliones* formed themselves into a guild under a presiding officer. A constitution of Diocletian prescribed a tariff of fees for them. As the craft grew in importance, the state began to exercise a control over them, and prescribed the terms of admission and removal of the

members. Laws were made to define the legal effect of the instruments which they framed. It was required that the *tabellio* be present at the execution of the instrument, and affix to it his signature and the date. Three witnesses must also subscribe their names ordinarily, but 4 were necessary if the principal parties could not read.—In imitation of these Roman officers, the Frankish kings created notaries, and guarded by laws against the abuse of their functions. During the middle ages notaries were appointed directly by the popes or emperors, or at least under their immediate authority. In France, by an ordinance of 1812, Philip the Fair forbade for the future the creation of notaries to all except prelates, barons, and those to whom appointment pertained as an ancient right in virtue of their estates. From that time onward notaries were invested in France with a qualified judicial character. They had authority, for example, to insert in the memoranda of obligations a clause granting summary execution to the creditor in case of a non-fulfilment of the contract. But this voluntary jurisdiction which notaries had so long possessed in France, was taken from them by the legislation of the republic. They are now public officers, formally recognized indeed as sharers in the civil administration, but deriving their authority from and representing rather the crown than the courts. They are commissioned for life, and can be removed only by judicial decree. They are authorized to draw instruments of various characters; and in matters which are of more than private importance, they retain in their custody the original drafts and furnish copies of them to the parties concerned. They are often employed under the direction of the courts in making out inventories and in the distribution of estates, and perform those notarial acts which are required by law in respect to wills, gifts, marriage contracts, and protests. Notarial chambers, which consist of deputies chosen by the profession, regulate the rules of practice, decide upon the admission of candidates, and punish members who are guilty of abuse of their office. All documents which were executed in the presence of two notaries, or of one notary and two witnesses, and are attested by them, receive full credence in all courts of law.—In Germany, the *Notariatsordnung*, which was issued in 1512 by the emperor Maximilian I., still partially defines in some states the powers of notaries. They are legitimated by diploma or commission, and on assuming their office adopt a seal which they cannot change without judicial permission. Their official duties consist generally in the preparation of contracts and the drawing of wills; in the authentication of deeds and powers; in framing appeals and inventories; in making protests upon mercantile paper, and in taking testimony for the courts. Writings which are certified by a notary and two credible witnesses, in the prescribed form, are equal in force and effect with public

records.—Notaries were known in England before the conquest. Little mention is made of them during the two or three next succeeding centuries. In the early part of the 14th century, however, they seem to have been commonly employed, for in 1347 we find them frequently named in the petitions of the commons to the king. Ever since that time, the office has been one of prominence and importance. Until very recently, as a public officer of the civil and canon law, the English notary derived his authority to practise from the court of faculties of the archbishop of Canterbury. The ecclesiastical courts were abolished by the statutes 20 and 21 Victoria, c. 77, 85; but these acts did not affect the notaries. The terms of their admission into the faculty of notaries are prescribed by the act 41 George III., c. 79, amended by the 3 and 4 William IV., c. 70, and 6 and 7 Victoria, c. 90. Their authority extends to the drawing of deeds relating to real and personal property, to protesting bills of exchange, authenticating and certifying copies of documents, and to the attestation of instruments going abroad. They receive the affidavits of mariners and ship masters, and draw their protests. English notaries have always considered themselves competent to administer oaths and affirmations.—The functions of notaries in the United States are similar to those exercised by the same officers in England, though in general they seem to be limited in practice to the attestation of writings of a mercantile kind, and to the protestation of bills and notes. They are usually commissioned by the executive of their states, and derive their particular powers from statute provisions. In Rhode Island they are elected annually by the general assembly. In New York the statute which defines their powers in respect to foreign and inland bills, drafts, and notes, confers upon them the further authority "to exercise such other powers and duties as by the law of nations and according to commercial usage, or by the law of any other state, government, or country, may be performed by public notaries." In New Hampshire, in addition to the usual powers of the office, notaries may take depositions, and acknowledgments of deeds before them have the same validity as those made before justices of the peace. Similar provisions are found in the statutes of Connecticut and Rhode Island; and in the former state notaries are expressly empowered to administer oaths. In those states where the powers of these officers are not distinctly set forth, it may be supposed that they include such acts as attach to the office by general mercantile usage.—In respect to the value of notarial acts in evidence, it may be remarked, in the first place, that the admissibility in evidence of notarial acts done in a foreign country, and their authenticity, rests solely on the ancient mercantile usage, which makes what may be termed the commercial law of nations. In respect to bills of exchange and similar paper of merchants, there

is no doubt of the effect of notarial acts. It is the rule as well of the English as of the American law that the minutes of a foreign notary of his protest for non-acceptance, when attested by his signature and notarial seal, are full proof of these facts, and require no auxiliary support. But the principle that the foreign notary's certificate is conclusive evidence only of such acts as he does under the law merchant, has been upheld in a case where a deed of partition made and acknowledged before a foreign notary was pronounced insufficient in respect to the acknowledgment; and in England the certificate of an American notary under seal of the execution of a power of attorney in his presence was not admitted as evidence of the fact, though the notary's certificate was verified by the British consul. Independently therefore of special laws, which in some states indeed give validity to acknowledgments and the like acts if done before foreign notaries, no certificates of theirs which concern matters foreign to the mercantile law will be recognized as evidence. The protest of a promissory note at home is not an official notarial act, as the protest of a foreign bill of exchange is; and therefore, after the notary's death, the note of such a protest is not of itself competent evidence in chief. Yet when it is duly authenticated by signature and seal, it will be admitted as secondary evidence of the notarial acts which it recites. So the memoranda entered in the office books of the notary, either by him in person or by his clerk in the ordinary course of business, are admissible in evidence when the party is dead who could directly speak to the fact. In some states, as New York, the competency and legal effect of notarial acts are determined by statute.

NOTHOMB, JEAN BAPTISTE, baron, a Belgian statesman, born at Messancy, in the grand duchy of Luxemburg, July 8, 1805. He was educated for the law, but in 1828 became one of the proprietors of the *Courrier des Pays-Bas* newspaper, in which he energetically assailed the Dutch administration, and advocated the necessity of a separation between Belgium and Holland. After the revolution of Sept. 1830, the provisional government appointed him one of the committee on the constitution, of which he was made secretary. He was a member of the national congress convened to decide upon the form of government, in which he resisted both the republican and Catholic parties, and aimed at the establishment of a constitutional monarchy. In this he acted in concert with MM. Lebeau, Devaux, Charles Rogier, and Van de Weyer. In the election of a king, he first favored the duke of Nemours, son of Louis Philippe; but this candidate having withdrawn, he supported Prince Leopold, who was chosen by a large majority. In the conference which met at London to settle the affairs of Belgium, Nothomb bore an influential part. He was general secretary under the minister of foreign affairs

until 1834, when, on the resignation of M. Lebeau, he was appointed *ad interim* to that ministry. In 1837 he was minister of public works in De Theux's Catholic cabinet. Through his efforts an admirable system of railways was established in Belgium. On the fall of M. de Theux in 1840, Nothomb sent in his resignation, and was appointed envoy extraordinary and minister plenipotentiary to the German confederation. The liberal ministry of Lebeau lasted but a few months, and a more moderate cabinet was formed in which Nothomb took the home department. In 1843 he became the head of a new administration, which, holding the balance between the liberals and the Catholics, lasted for two years, but finally succumbed to a coalition of both the opposition parties. Nothomb was now sent as ambassador to Berlin, a position which he still holds. He published in 1833 a pamphlet entitled *Essai historique et politique sur la révolution Belge*.

NOTORNIS (Gr. *voros*, south, and *opos*, bird), a large bird of the rail family, established by Owen in 1848 (see "Transactions of the Zoological Society," vol. iii. p. 366) on a nearly entire skull sent with those of the *dinornis* from New Zealand. The natives had traditions of the existence of a large rail-like bird which they called *moho*, contemporary with the *moa* or *dinornis*, but it was by them considered extinct like the latter. This bird, which Owen called *N. Mantelli*, was known only by the occasional occurrence of its bones, until Mr. Walter Mantell, in 1849, obtained a skin from the Middle island of New Zealand. A specimen was there taken alive by some sealers after a long chase; it ran very rapidly, and when captured screamed and struggled violently; after having been kept 8 or 4 days, it was killed, and its flesh found delicious; the skin was sent to England, where a description was made by Mr. John Gould, confirming entirely the opinion of Owen based upon the bony structure. (See "Annals and Magazine of Natural History," 1852, vol. ix., pp. 281-6, taken from "Proceedings of the Zoological Society," part xviii., 1850.) The bird had the aspect of a large *porphyrio* in the bill and the color, but had the moderate feet of *tribonyx*, with the rudimentary wings and tail of an ostrich. The length was 26 inches, the bill to gape $2\frac{1}{2}$, the wing $8\frac{1}{2}$, and the tarsi and tail each $3\frac{1}{2}$; the bill was shorter than the head, much compressed on the sides, with the culmen elevated and arched, extending on the forehead as far as the posterior angle of the eye; wings very short, rounded, slightly concave; the primaries soft and yielding, the 1st short, and the 8d to the 7th equal and longest; feathers of tail soft and loose; tarsi powerful, almost cylindrical, very broad in front and defended by wide scutellæ; anterior toes large and strong, shorter than the tarsus, with powerful hooked nails; hind toe short, strong, rather high up, with a blunt hooked nail. The head, neck, breast, upper part of abdomen and sides

purplish blue; back, rump, upper tail coverts, lesser wing coverts, and tertiaries dark olive green tipped with verditer green; on the nape a band of rich blue separating the purplish blue of the neck from the green of the body; wings rich deep blue, the greater coverts tipped with verditer green; tail dark green; lower abdomen, vent, and thighs bluish black; under tail coverts white; bill and feet red. From the thickness of the plumage, and the great length of the feathers of the back, it is believed that this bird inhabited marshy places and coverts of damp ferns; it was essentially terrestrial, yet probably able to swim; though unable to fly, it was a very rapid runner; it was doubtless very shy, keeping concealed, naturally or to avoid enemies, in the darkest and thickest recesses of the islands. This is a very interesting addition to the list of wingless birds, like the *dinornis*, dodo, and kiwi-kiwi (*apteryx*), which have become extinct since the advent of man, or are on the verge of annihilation by human agency; it is also a striking example of the accuracy with which the naturalist can construct an animal, and determine its family and almost its generic characters, from the examination of a few bones.

NOTT. I. ABRAHAM, an American judge and politician, born in Saybrook, Conn., in 1767, died in Fairfield, S. C., in Jan. 1880. He was graduated at Yale college, and studied for the ministry, but did not take orders. About 1788 he proceeded to Georgia, where he was occupied for a year as a teacher. He studied law in Camden, S. C., was admitted to the bar in 1791, married in 1794, and settled on a plantation on the Pacolet river, but continued the practice of his profession. In 1800 he was elected to congress by the federalist party, and was one of those who repeatedly gave the vote of South Carolina for Burr against Jefferson. He practised law with eminent success in Columbia, S. C., from 1804 to 1810, when he was elected one of the judges of the court of appeals. II. HENRY JUNIUS, an American scholar and author, son of the preceding, born on the Pacolet river, Union district, S. C., Nov. 4, 1797, drowned off the coast of North Carolina, Oct. 18, 1887. He was graduated at the South Carolina college in 1812, made a brief visit to Europe, and on his return in 1818 was admitted to the bar. He became law partner with D. J. Maccord, with whom he edited two volumes of reports covering the cases decided by the constitutional court in 1818, '19, and '20. His health failing, he sailed again to Europe in 1821, married a European lady, and during his absence was elected to the chair of criticism, logic, and the philosophy of language in the South Carolina college. He remained a professor for 18 years in that institution, at the same time being a contributor to the "Southern Review." He made a collection of his "Novelettes of a Traveller, or Odds and Ends from the Knapsack of Thomas Singularity, Journeyman Printer" (2 vols.,

New York, 1834), chiefly of a humorous character. A historical romance which he had nearly completed at his death has not been published. In 1837 he visited New York, took passage thence in the steamer Home, and perished in its wreck at sea with his wife.

III. JOSIAH CLARK, an American ethnologist, brother of the preceding, born in Columbia, S. C., March 31, 1804. He was graduated at the South Carolina college in 1824, took his degree of M.D. in Philadelphia in 1827, and, after remaining two years longer in that city, in the capacity of demonstrator of anatomy to Dr. Physick, returned to Columbia, and commenced the practice of his profession. In 1835 he went to Europe, and spent that and the next year there in the study of medicine, natural history, and the kindred sciences. Since his return he has practised medicine in Mobile, Ala. Beside contributing many articles on professional and kindred topics to the medical journals of the country, he has published several ethnological works which have attracted great attention in Europe as well as the United States. Among these are "Two Lectures on the Connection between the Biblical and Physical History of Man" (8vo., New York, 1849); "The Physical History of the Jewish Race" (Charleston, 1850); "Types of Mankind" (4to., Philadelphia, 1854); and "Indigenous Races of the Earth" (4to., Philadelphia, 1857). The last two were prepared in connection with Mr. George R. Gliddon. The object of these works is to refute the orthodox theory of the unity of the human race, by showing that the present types of mankind lived around the Mediterranean 8,000 years B. C., and that there is no evidence that, during the last 5,000 years, one type has been changed into another. In 1857 Dr. Nott was called to the chair of anatomy in the university of Louisiana, but resigned it after one winter's service, to resume his profession in Mobile. Recently he has succeeded in establishing a medical college in Mobile, which the legislature of Alabama has endowed with \$50,000, and made a branch of the state university. Its first session opened in Nov. 1859.

NOTT, ELIPHALET, D.D., LL.D., president of Union college, an American clergyman and educator, born in Ashford, Windham co., Conn., June 25, 1778. He is to a great extent self-educated, having never received a collegiate training. He studied divinity in his native county, and at the age of 21 was sent out as a domestic missionary to the central part of the state of New York. On passing through the old settlement of Cherry Valley, he was requested to take charge of the Presbyterian church at that place. He accepted the call, and in addition to his pastoral duties became the teacher in the academy. Two or three years afterward he was called to the Presbyterian church at Albany, where he at once took a prominent position as a preacher, and was listened to by crowded congregations. Among his most successful pulpit efforts while

at Albany was a sermon on the death of Alexander Hamilton. In 1804 he was chosen president of Union college, Schenectady, N. Y., which place he has continued to fill for 56 years; and he is now (1861) the oldest head of a literary institution in the United States, and probably in the world. More than 8,500 students have been graduated during his presidency, and in their number may be found some of the most eminent men in the country. Union college is emphatically of his own formation. He came to it in its poverty and infancy, and has raised it to wealth and reputation. In 1854 the semi-centennial anniversary of his presidency was celebrated, when between 600 and 700 of the men who had been graduated under him came together to do him honor. Dr. Nott has been an earnest advocate of the temperance cause, and published "Lectures on Temperance" (Albany, 1847). Though he has written much, his other publications are confined principally to occasional addresses and "Counsels to Young Men" (18mo., New York). He has given a great deal of attention to the laws of heat, and beside obtaining 30 patents for applications of heat to steam engines, the economical use of fuel, &c., is the inventor of a stove bearing his name which has been very extensively used.

NOTTINGHAM, a parliamentary and municipal borough and market town of England, capital of Nottinghamshire, and a county in itself, situated on the river Leen near its junction with the Trent, and on the Nottingham canal and the midland railway, 108 m. N. N. W. from London; pop. in 1851, 58,529, or including Sneinton and Radford, which have since been incorporated with it, 80,006. The suburban villages dependent upon Nottingham have a population of about 80,000. The town is built on the side of a steep hill, and many of the streets rise in terraces. The older quarters present a picturesque but crowded appearance, and the modern parts of the town are laid out with good taste. There are several pleasure grounds, including an arboretum of 18 acres, and a park of 180 acres belonging to the duke of Newcastle, both of which are open to the public. On the summit of a precipitous rock 133 feet above the surrounding meadows are the ruins of "the castle," a large mansion built by the duke of Newcastle in 1674, on the site of a fortress erected in the time of William the Conqueror, and burned in the reform riots of 1831. Beside about 40 churches and chapels, the principal public buildings are a large convent, the exchange, corn exchange, guildhall, county hall, house of correction, union workhouse, barracks, assembly rooms, theatre, and mechanics' hall. Among the schools and charitable institutions are a free grammar school, Unitarian free school, blue coat, British national, infant, and ragged schools, the people's college (founded in 1846 to afford superior education to the working classes), lunatic and blind asylums, and 5 hospitals. There are sev-

eral libraries, a government school of design, and a mechanics' institute. The principal manufactures are lace, and cotton and silk hosiery. The lace manufacture owes its importance mainly to the invention of the bobbinet machine in 1809 by John Heathcoat, a Nottingham artisan, and to the subsequent application of the Jacquard loom. In 1867 about 3,600 bobbinet and 800 warp lace machines were in operation, and the annual product of lace was £4,780,000. The value of hosiery made at the same time was £2,100,000. There are several other manufactures of minor importance, and the Nottingham ale is celebrated in popular song. The borough returns 2 members to parliament.—Nottingham is a place of great antiquity, and derives its name from the Saxon *Snotingham*, which is descriptive of its position as a retreat in rocks, since there were formerly many caverns in the soft rock on which its castle was built, of which a few remain. During the wars of the barons the castle was attacked and taken by the earl of Derby, and after the deposition of Edward II. it became the residence of Queen Isabella and her paramour the earl of March. Several parliaments were held here. In 1485 Richard III. marched from Nottingham, where he had assembled his forces, to the battle of Bosworth field. In the civil war Charles I. set up his standard in Nottingham in 1642, but the place fell the next year into the hands of the parliament.

NOTTINGHAM, EARL OF, lord chancellor. See **FINCH, HENRAGE**.

NOTTINGHAM, EARL OF, lord high admiral. See **HOWARD, CHARLES**.

NOTTINGHAMSHIRE, or **NOTTS**, an inland county of England, bounded N. W. by Yorkshire, N. E. and E. by Lincolnshire, S. by Leicestershire, and W. by Derbyshire; area, 822 sq. m.; pop. in 1851, 270,427. The face of the country is generally level, with moderate undulations. The celebrated royal forest of Sherwood, the traditional scene of Robin Hood's exploits, was in this county, lying N. E. of Nottingham, and extending about 21 m. in length by a breadth varying between 7 and 9 m. A portion of this forest is still in existence, forming part of Earl Manvers's park at Thoresby, and is known by the name of Birkland forest. All this tract, with the above and a few other trifling exceptions, has now been enclosed. The geological formation on which the county rests is the new red sandstone; and red marl, and its varieties of sand, gravelly sand, and red and white sandstone, constitute by far the greater part of the soil. Coal pits have been sunk to considerable depths in various places; the seams vary in thickness from 1 to 6 feet; the coal is inferior to that of Newcastle. Gypsum is extensively worked near Newark, and a very good yellowish freestone for building and paving is obtained in various places; marl is also found throughout the county. The climate is healthy and comparatively dry. The principal crops are wheat, barley, oats, turnips, and

clover. There are excellent market gardens and some good orchards near the principal towns. The river Trent, which has a course of about 60 m. through Nottinghamshire, is a broad navigable stream bordered by level lands. There are many canals and railways. The chief manufactures, beside malt in great quantities, are paper, iron, ropes, candles, ale, earthenware, lace, and hosiery. The N. and S. divisions of the county (N. and S. Notts) send each 2 members to parliament, and its boroughs 6, making 10 in all.

NOTTOWAY, a S. E. co. of Va., bounded S. by the Nottoway river; area, about 800 sq. m.; pop. in 1850, 8,487, of whom 6,050 were slaves. The productions in 1850 were 216,991 bushels of Indian corn, 2,109,314 lbs. of tobacco, and 10,691 of wool. There were 18 grist mills, 3 tanneries, 13 churches, and 260 pupils attending public schools. The value of real estate in 1856 was \$1,905,815, showing an increase of 71 per cent. since 1850. The Richmond and Danville and the Petersburg and Lynchburg railroads intersect the county, the latter passing through the capital, Nottoway Court House.

NOUN. See **LANGUAGE**, vol. x. p. 295.

NOUREDDIN (**MALEK-AL-ADEL NOOR-ED-DEN MAHMOUD**), a Mohammedan ruler of Syria, born in 1117, died in Damascus, May 15, 1174. He was a younger son of Zeugli, of the Atabek dynasty of Irak and Syria and emir of Aleppo, and succeeded his father in 1145. At the beginning of his reign the Christians were endeavoring to regain possession of the dominion which had been taken from them; and in the prosecution of this enterprise Edessa was assaulted by Joscelin de Courtenay. He was repulsed however by Nouredin, who demolished the walls, and massacred all the inhabitants who had given assistance to the enemy. In 1147 the second crusade, headed by Louis VII. of France and the emperor Conrad III., set out from Europe with the avowed object of recovering this fortress; but the numbers of the vast host which they led were diminished in the march through Asia Minor to Palestine by the sword of the Turks, and its power was weakened by the jealousy of the leaders. The Christians began the siege of Damascus, but finally returned to Europe without having accomplished any thing. No sooner had they departed than Nouredin resumed the offensive, with the determination of crushing out the Christian power in Palestine. Invading the territory of Antioch, he defeated and slew Prince Raymond; and, although routed the following year by Joscelin de Courtenay, he was fortunate enough soon after the battle to capture that military leader. The whole of northern Syria now fell into his hands. In 1154 the inhabitants of Damascus, ruled by an imbecile monarch, and dreading an attack from Baldwin III., king of Jerusalem, who had lately taken Ascalon, sought the protection of Nouredin. He rebuilt and adorned that city, and made it

the capital of his dominions, which now extended to the frontiers of Egypt, and enclosed on the land side the Christian possessions in the East. The war still continued, the Moslem arms remaining on the whole triumphant; but in 1159 Noureddin's severe sickness, with a false report of his death, retarded his success. The Greek emperor, Manuel Comnenus, and the Franks of Antioch formed an alliance against him; but the former was bought off, and the latter succeeded only in gaining the fortress of Al-Harem, which was subsequently recaptured. In the progress of the war the emir defeated and took prisoner the famous Reginald de Châtillon, prince of Antioch. Turning his attention to Egypt, where the dissensions of the Moslem leaders afforded him a pretext for interference, and extending his sway in that quarter, he sent an army under Sheerkook to the support of the emir Shawir against his rival Ed-Dargam. Shawir, however, having gained the throne, formed an alliance with the Franks, and compelled the troops of Noureddin to depart from Egypt; but refusing to fulfil his engagement with the Christians, he was compelled, in order to escape their vengeance, to apply again to the Syrian monarch. Hereupon Sheerkook, at the head of a Moslem army, entered Egypt a second time, forced the Franks to retreat, put Shawir to death, and ruled Egypt as the lieutenant of Noureddin, who was dignified with the title of sultan by the caliph of Bagdad, and received from that head of the faithful the direct investiture of Syria and Egypt. He had now attained the height of his power, but the remaining years of his life were disturbed by the ambition of Salah-ed-Deen (Saladin), who had succeeded his uncle Sheerkook as ruler of Egypt. Though professing a nominal obedience to his master, he had made himself independent, and disregarded to a great extent the wishes of his sovereign. Noureddin was on the point of marching into Egypt to reduce his rebellious subject, when he was seized with an attack of quinsy, of which he died. Both Moslem and Christian writers unite in the praise of his character. Among the latter, William of Tyre speaks of him as "a prudent and discreet man, who feared God according to the faith of his people;" and among the former his titles of Malek-al-Adel (the just prince) and Noor-ed-Deen (light of the faith) sufficiently attest his reputation. He was exceedingly liberal to the poor, distributing among them every month 5,000 dinars, and establishing a chamber of justice for their protection, and for the purpose of checking the excesses of the military leaders.

NOVA SCOTIA (New Scotland), a province of British North America, bounded N. W. by the bay of Fundy, the province of New Brunswick, Northumberland strait, and the gulf of St. Lawrence, and on all other sides by the Atlantic ocean. It consists of the peninsula of Nova Scotia, a tract of land 280 m. long and from 50 to 100 m. wide, trending E. N. E., and connected with New Bruns-

wick by an isthmus about 8 m. wide on its N. side, between the bay of Fundy and Northumberland strait; and of the island of Cape Breton, which lies at the E. extremity of the peninsula, and is separated from it by the gut of Canso. (See CANZ BARROW.) The area of Nova Scotia proper is 15,607 sq. m., and of Cape Breton 3,120; total, 18,727 sq. m. Pop. of Nova Scotia in 1851, 248,587; of Cape Breton, 27,580; total, 276,117.—Nova Scotia proper lies between lat. 43° 25' and 46° N., and long. 61° and 66° 30' W. It is divided into 14 counties, viz.: Annapolis, Colchester, Cumberland, Digby, Guysborough, Halifax, Hants, King's, Lunenburg, Pictou, Queen's, Shelburne, Sydney, and Yarmouth. The principal cities and towns are Halifax, the capital, Pictou, Windsor, and Annapolis.—The coasts are indented with a great number of excellent bays and harbors, and between Halifax and the gut of Canso alone there are 24 commodious havens, 10 of which will accommodate ships of the line. Chedabucto bay, at the entrance of the gut of Canso; Halifax harbor and Margaret's and Mahon bays, on the S. coast; St. Mary's bay, Annapolis basin, Mines basin, and Chignecto basin, on the bay of Fundy; and Pictou harbor on Northumberland strait, are some of the principal inlets. Cape Canso, at the mouth of the gut of Canso; Cape Sable, the S. E. extremity of the province; and Cape Chignecto, at the end of a peninsula jutting out into the bay of Fundy from the isthmus which connects Nova Scotia with the mainland, and having at either side of it Mines basin and Chignecto bay, are among the most remarkable headlands. The coasts throughout are lined with islands, close to which there is deep water. On the Atlantic coast particularly the rocks and islands form a sort of natural breakwater within which vessels sail in comparative safety, while the sea outside is rough and dangerous. About 85 m. from Nova Scotia, but considered as belonging to it, lies Sable island, 25 m. long and 1½ m. wide, surrounded by an extensive bank, and consisting of little else than a sandy waste. Being in the track of vessels sailing between the United States and Europe, it is the scene of frequent shipwrecks, and a party of wreckers are maintained on it by the provincial government. The principal rivers of Nova Scotia are the Annapolis and Shubenacadie, flowing into the bay of Fundy; the East, West, and Middle rivers, into the harbor of Pictou on Northumberland strait, all of which are navigable; and the Avon, Havre, Mersey, Medway, Clyde, Shelburne, Tusket, and St. Mary. The Shubenacadie canal, in connection with a chain of lakes, forms an inland water communication from the harbor of Halifax to Cobequid bay. Lakes are numerous, but with the exception of Lake Rossignol, which is 30 m. long, they are all small. The surface is undulating, and though there are no mountains there are several ranges of hills, most of which traverse the country in an E. and W. direction.

The highest point, Ardoise hill or Arthur's Seat, is only 810 feet above the level of the sea. Upon the shore of the Atlantic the land has a general height of 500 feet, and is hilly and rugged, and continues to be so for from 30 to 50 m. inland. The soil varies much in quality and fertility. The valleys are exceedingly rich, and produce large crops of different kinds of grain, potatoes, turnips, and all the fruits and vegetables common to temperate climates. Along the S. shore the soil of the highlands is light and poor, but toward the N. there are extensive tracts of fertile uplands.—The geological formations of Nova Scotia range lengthwise with the peninsula from S. W. to N. E. Along the S. coast the crystalline granitic and quartz rocks prevail, interspersed with belts of clay slates and other metamorphic rocks. In the interior are argillaceous slates which afford quarries of good roofing slates. Still further N. the slaty formations become less metamorphic, and some are recognized by the fossils they contain as belonging to the Hamilton group of the upper silurian; and beyond these, toward St. Mary's bay and the extension of its line up the Annapolis river, are strata of the devonian and carboniferous periods. The latter abut against the metamorphic (gneissoid) range of the Cobequid hills, supposed to be of devonian age; and near the line of contact of these formations, among strata of quartz rock and of olive slates, is found a large bed of rich iron ores, very complex in character, consisting of micaceous specular and ochreous ores, with some magnetic ore, spathic iron, and also carbonate of lime. In one place the bed appears to be 120 feet thick. It is traced several miles in the vicinity of Folly and Great Village rivers, and has been worked at several points. East of Folly river it is found at the workings of the Londonderry mining company from 10 to 18 feet thick, and consists chiefly of micaceous specular ore intermixed with blocks of the ferruginous dolomite known as ankerite. For several miles the ore ranges within 300 to 500 yards of the lowest coal bed. Similar beds of ore are met with along the same range in the devonian slates of Morse river, Nictau, and at the E. extremity of the peninsula in the same group in Pictou. At the latter locality, within 40 m. of the Albion coal mines, the ore is very abundant, yielding 40 per cent. iron. At Morse river the bed is 6 feet thick, partially converted into magnetic ore, but the sheets of it abound in impressions of marine shells, and contain carbonate of lime derived from these organisms. The coal measures are divided into several separate fields by the interposition of lower rocks. In the district of Hants and Colchester they form a long strip S. of the Cobequid hills, and another in the valley of the Musquodoboit river. North of the Cobequid hills is the Cumberland coal field, which unites on the N. W. with that of New Brunswick; and in the N. E. end of the peninsula, uniting with each of the others, is the Pictou coal field. The formation is divided

into two groups: the upper, about 8,000 feet thick, consists of grayish and reddish sandstones and shales with beds of conglomerate, and thin beds of limestone and coal; and the lower, about 4,000 feet thick, is composed of dark gray sandstones and shales, with reddish and brown beds of bituminous limestone, of iron ore, and very valuable beds of coal; and still below these is a continuation of sandstones and shales known as the gypsiferous formation, amounting to 6,000 feet in thickness, containing in the upper part reddish and gray sandstones and shales, and below these conglomerates and also thick beds of limestone and gypsum. Marine fossils are found in the lower coal measures and the gypsiferous formation, intermingled with terrestrial organic remains, such as the upper measures contain alone. At the South Joggins on Chignecto bay are remarkably fine exposures of these strata along a range of about 10 m., dipping from 19° to 25°. They were measured by Sir William Logan, and the total thickness was found to be 14,571 feet. No fewer than 76 coal beds were counted among the strata. The most productive coal mines of the province are those of Pictou. (See COAL, vol. v. p. 388.) Quarries of gypsum are extensively worked in the vicinity of Mines basin, and this rock as well as limestone abounds along the belt of country from Minadie to Pugwash. The sandstone strata are quarried in many localities for grindstones, the exports of which from Cumberland in 1851 amounted to 36,712 tons; and the same rocks also afford beautiful building stones of a light brown color, which have lately been introduced to considerable extent into New York and Boston. The quarries of these are at Dorchester at the head of Chignecto bay, and also at the head of Pictou harbor. Along the S. side of the bay of Fundy is a narrow belt of trap rock extending from Brier island to Cape Blomidon, a distance of about 130 m. It forms ranges of rude columns in bold precipices, not unlike the palisades of the Hudson. The rock, however, is more varied in its character, as it is intermixed with the red sandstones and shales; and among the amygdaloids which abound along this coast are found the greatest variety of interesting minerals peculiar to this formation. These are described by Messrs. Jackson and Alger in a paper "On the Mineralogy and Geology of Nova Scotia," published in the "Proceedings of the American Academy of Arts and Sciences" (vol. i., new series, 1838). See also Prof. J. W. Dawson's "Acadian Geology," and Lyell's "Travels in North America."—The climate is remarkably healthy, and its rigor is greatly moderated by the almost insular position of the country and by the Gulf stream, which keeps the ports facing the Atlantic free from ice in winter. The thermometer ranges from 8° below zero to 80° above it; the average of the coldest month at Halifax is 20°, and that of the hottest 70°. Though the spring is backward, vegetation is remarkably rapid. The temperature sometimes varies 50° in 24

hours; but the weather is considered preferable to that of Canada East, as it is milder in winter and not so excessively hot in summer.—About one fifth of the area of Nova Scotia is occupied by lakes, rivers, estuaries, inlets, and arms of the sea. In 1850, 839,322 acres were cultivated, 40,012 of which consisted of alluvial marshes reclaimed from the sea along the bay of Fundy by means of dikes. In 1852 the agricultural produce was as follows: wheat, 297,157 bushels; barley, 196,097; rye, 61,438; oats, 1,884,437; buckwheat, 170,801; Indian corn, 84,475; peas and beans, 21,638; grass seeds, 3,686; potatoes, 1,986,789; turnips, 467,127; other roots, 32,325. In the same year there were produced 287,837 tons of hay, 3,613,890 lbs. of butter, and 652,069 lbs. of cheese. In 1851 there were 28,789 horses, 243,718 horned cattle, 282,180 sheep, and 51,533 swine. Many of the inhabitants find employment in fishing, and some combine the occupations of both fishermen and farmers. Nearly all the species of fish found in the North American seas frequent the shores of Nova Scotia. In 1851 there were 812 vessels of 43,833 tons employed in the fisheries, with crews of 8,681 men, and 5,161 boats with 6,713 men. The number of seines and nets was 30,154. The fish cured amounted to 8,769 tons, beside which there were 1,669 barrels of salmon, 3,536 of shad, 100,047 of mackerel, 53,200 of herring, 5,343 of alewives, and 15,409 of smoked herrings; the whole valued at £217,270. Fish oil to the extent of 189,250 gallons, valued at £17,754, was also produced. The wild animals and birds are the same as those generally found in other parts of North America, but, with the exception of some of the smaller species, their numbers have been greatly reduced.—The manufactures are not numerous. In 1850 there were 1,153 saw mills, 886 grist mills, 237 tanneries, 9 foundries, 81 carding and weaving establishments, 17 breweries and distilleries, and 181 other manufactories of different sorts. In the same year the value of the principal articles made was as follows: leather, £52,625; boots and shoes, £73,654; iron, £8,121; soap, £28,277; and candles, £21,210. There were 114,992 chaldrons of coal and 79,795 tons of gypsum raised, 28,603 casks of lime burned, and 2,845,400 bricks and 110,441 lbs. of maple sugar made. Ship building is an important branch of industry in Nova Scotia. In 1854 there were built 244 vessels, measuring 52,814 tons. The exports consist principally of fish, timber, beef, pork, grindstones, gypsum, lime, and coal; and the value of the whole in 1854 was £1,247,668. The value of imports in the same year amounted to £1,791,082. The entrances in 1851 were 3,402 vessels, tonnage 340,039, and the clearances 3,247 vessels, tonnage 338,038. A considerable trade is carried on between the United States and Nova Scotia in coal, fish, tobacco, and various manufactured goods.—The inhabitants are mostly of English, Scotch, and Irish descent. The western coun-

ties are principally occupied by the descendants of loyalist emigrants from the United States. The Irish are generally settled in the capital, and the Scotch in the eastern counties. There are some settlements composed of the descendants of French colonists; and in the county of Lunenburg there is a race sprung from some German and Swiss Protestants who emigrated from Europe in 1753. The Indians number only about 1,000.—The province contains several colleges, but the attempts made to form a university by uniting some of them have hitherto been unsuccessful. In 1851 there were 1,096 schools, attended by 31,354 scholars. In 1854 the public expenditures for education amounted to £13,401. The militia force of the colony is composed of 26,248 men, divided into 26 regiments, beside which there are generally 2 or 3 regular British regiments quartered in the principal towns. The Presbyterians, Episcopalians, Roman Catholics, and Baptists are the most numerous religious denominations. The church of England is established by law, and the amount expended for ecclesiastical purposes in 1854 was £3,687. Nova Scotia was created a diocese in 1787. The bishop and archdeacon are supported by the government of Great Britain, and 50 clergymen under them are paid by the society for the propagation of the gospel. There are two Roman Catholic bishops within the province, those of Cape Breton and Nova Scotia. In 1851 there were 567 churches belonging to all denominations in the colony.—The executive officer of Nova Scotia is styled lieutenant-governor. He is assisted by a council of 6 members. The legislature consists of a council of 19 appointed by the governor subject to the approval of the crown, and a house of assembly elected by the people; and the colonial revenue is entirely under their control. The common and statute laws of England, altered slightly in some cases to suit local requirements, are in force in Nova Scotia. The revenue of the colony, principally raised by duties on imported goods, amounted in 1854 to £166,501, and the expenditures for the same year to £169,159. The expenditures of the British government on account of Nova Scotia amounted in 1857 to £154,605.—Nova Scotia is said to have been discovered by the Cabots in 1497; but the first attempt to colonize it was made by De Monts and some other Frenchmen, together with a few Jesuits, in 1604. They called the country Acadia, and for 8 years made efforts to form settlements at Port Royal, St. Croix, and some other places; but they were at length expelled by the colonists of Virginia, who claimed Nova Scotia by right of original discovery. In 1621 Sir William Alexander obtained a grant of the peninsula from James I., and in the patent it was called Nova Scotia. Alexander's intention was to colonize the country upon an extensive scale; but when the colonists arrived, in 1623, they found the localities where they intended to form settlements already occupied by foreign adven-

turers. They did not consider the attempt to establish themselves prudent, and therefore returned to their native country. In the reign of Charles I. the Nova Scotia baronets were created. They were not to exceed 150 in number, and were in fact a kind of joint stock company for colonizing the country, each of whom was to receive an allotment of land in proportion to the aid furnished. The French obtained a footing in Nova Scotia a second time, and were not subdued till Cromwell sent a strong force against them in 1654. England ceded the country to France by the treaty of Breda in 1667; but the English continued from time to time to ravage the French settlements, and in 1713 Nova Scotia was restored to them. For some years it was much neglected; but in 1749 efforts were made to colonize it by emigrants sent out at the expense of the British government. Some 4,000 settlers and their families reached the colony in this way, and founded the town of Halifax. The French, who were still numerous, caused considerable annoyance and loss to the English by joining the Indians in making war upon them. They were at length either expelled or subdued, and Louisburg, their chief stronghold on the island of Cape Breton, captured. A constitution was granted to Nova Scotia in 1758; and by the treaty of Paris (Feb. 1763) France renounced all future claim upon any of her former possessions in North America. New Brunswick and Cape Breton were separated from Nova Scotia in 1784, but the latter was reannexed in 1819.

NOVA ZEMBLA (Russ. *Novaya Zemlia*, new land), several islands situated in the Arctic ocean, which belong to Russia and form a dependency of the government of Archangel, between lat. 70° 30' and 76° 30' N., and long. 51° 30' and 77° E. Nova Zembla is separated from the island of Vaigatz, which lies close to the mainland, by the strait of Kara, and from the continents of Europe and Asia by the sea of Kara. The southernmost island of the chain is separated from the others by Matthews's strait, and further N. there is another strait called Cross bay, which has several arms and forms numerous islands. The term Nova Zembla belongs properly to the S. island alone, while the one in the centre is called Matthews's land, to the N. of which are situated Lütke's and Barentz lands, supposed to form one island. The mountains upon the W. coast have a general height of about 2,000 feet above the sea, the greatest elevation being 3,475 feet. The geological formation is mostly clay slate and gray limestone. The soil is barren, the only vegetation being mosses and lichens, and in some places a few stunted shrubs. The mean summer temperature at the S. extremity is 35.51°, and that of winter 3.21°. The islands have no permanent inhabitants, but are visited by fishermen and hunters from the mainland. Fish, whales, and walrus are abundant on the coasts; and reindeer, arctic bears, and foxes are numerous on the islands. Nova Zembla has

been frequented by Russian hunters for many centuries, and of late years several exploring expeditions have been sent thither by the czar.

NOVALIS. See HARDENBERG, FRIEDRICH VON.

NOVARA, a province of Sardinia, bounded N. by the Lepontian Alps and Switzerland, E. by the Ticino and the Lago Maggiore, which separate it from Lombardy, S. by the Po, which separates it from the province of Alessandria, and W. by the provinces of Torino and Aosta. It comprises 6 arrondissements, which, with their area and population, are as follows:

Arrondissements.	Area in sq. m.	Pop. in 1868.
Novara.....	550	190,650
Biella.....	378	124,540
Osola.....	684	83,748
Pallanza.....	294	61,110
Valesia.....	314	83,315
Vercelli.....	509	181,125
Total.....	2,629	573,592

The principal part of this division of Sardinia belonged to the former duchy of Milan, and is covered by the main ridge of the Alps, which encloses the valley of the Tosa, into which numerous lateral valleys open, each adding its tributary stream to the Tosa, which finally discharges its waters into the Lago Maggiore.—The arrondissement of Novara, situated between the rivers Sesia and Ticino, is level in its central and southern portions, which form part of the great plain of the Po, but hilly in the north. The soil is noted for its fertility. The principal products are grain, rice, hemp, and silk.—NOVARA, the capital of the province, is situated 10 m. from the left bank of the Ticino, on the high road from Milan to Turin, and about 60 m. W. by railway from the latter city; pop. 26,963. It is surrounded with walls and bastions. Parts of the old fortifications are dismantled, and afford pleasant walks with fine views of Monte Rosa and other spurs of the Alps. The cathedral of Novara is an early Lombard building, celebrated for its splendid high altar, for frescoes by Luini and some sculptures by Thorwaldsen, and for its archives, rich in antiquities of the lower empire and the middle ages, and above all for its music. The church of San Pietro al Rosario is noted for the sentence passed there in 1307 on the priest Dolcino, referred to in Dante's *Inferno*, who was condemned for preaching Manichæism and communistic principles, and was burned alive at Vercelli together with his mistress Margaret, a beautiful nun whom he had taken from her convent. Novara is famous for the battle fought there, March 23, 1849, between the Sardinians under Gen. Ckrzanowski and the Austrians under Radetzky. The Sardinian army was completely routed, which led to the abdication of Charles Albert in favor of his son Victor Emanuel, and, among other humiliating conditions of peace, to the renunciation on the part of Sardinia of all claims to the sovereignty of Lombardy.

NOVATIAN, the founder of a schismatical sect in the Christian church in the 3d century. He was a presbyter of Rome, and by his learning, eloquence, and theological writings had won a high reputation. He held that persons who had committed the more grievous sins, and especially those who had denied their faith during the Decian persecution, ought not to be received again into the church. One of the foremost defenders of the contrary opinion was the priest Cornelius, who in 250 was proposed to succeed Fabian in the see of Rome. Novatian, unable to prevent his election, withdrew from communion with him, was excommunicated by a council held at Rome in 251, and was almost immediately afterward set up as a rival bishop by his own party. His principal coadjutor was Novatus, a presbyter of Carthage, who had already become notorious by his violent opposition to Cyprian, the bishop of that see. Respecting the fundamental doctrines of the church there was no disagreement between the Novatians and other Christians. "Their peculiarity was," says Mosheim, "that they would not receive into the church persons who after being baptized fell into the greater sins. They did not, however, exclude them from all hopes of eternal salvation. They considered the Christian church therefore as a society of innocent persons, who from their entering into it had stained themselves with no grievous sin; and hence it followed that in their eyes all associations of Christians which opened the door for the return of gross offenders were undeserving of the name of true churches of Christ. Hence they assumed the name of *ca-thari*, or the pure, and moreover rebaptized those who came over to them from the Catholics." The sect lasted until about the 5th century.

NOVATION, a law term introduced recently into use by English and American lawyers, from the Roman civil law. It may be defined as the creation of a new debt or contract in substitution for an old one. It differs from a mere renewal, such as takes place when A renews a credit he has given B, or receives a new debt or obligation from B in payment of an old one. To a novation there are three parties. It takes place when A owes B, and C owes A, and A transfers to B in payment of his debt C's debt to him, A. The effect of this is, that A is no longer the debtor of B nor the creditor of C; and B is no longer the creditor of A, but has become the creditor of C; and C is no longer the debtor of A, but has become the debtor of B. In the civil law, the new contract of C to pay B, and the discharge of A's debt to B by the transfer of A's claim on C, would be regarded as different forms of novation. By our law, however, it is one thing, and the whole transaction forms one novation. It is a universal principle in the law of England and of this country, that a promise can be enforced at law only when it is founded upon a consideration. This rule is applied to the case of novation; the effect

of it is, that the original liabilities must be extinguished and discharged by the novation, and their discharge is then a sufficient consideration for the new liabilities. Thus, C becomes the debtor of B by the above described novation; and when B claims the debt of C, the consideration on which the claim can be upheld is the fact that C's debt to A was discharged. So if B claims the debt from A, and A interposes his agreement to release him, that agreement is valid only because B has received C's debt to A by way of consideration for his release of A. Thus all the parts of this transaction are mutually connected and dependent. Hence, an order by a creditor to his debtor, directing him to pay the debt to some one to whom the creditor is indebted, operates as the substitution of a new debt for an old only when the order is accepted, and when the original creditor of him who drew the order has agreed to receive the accepted order in payment of his claim. This transaction may be oral only, none of the promises being in writing, because C, the original creditor of A, does not undertake to pay A's debt to B, inasmuch as A's debt is entirely discharged by the novation; but C contracts a new debt to B. This therefore does not come under the provision of the statute of frauds, requiring that the promise to pay the debt of another should be in writing. Hence also, if, after the transaction is complete, C wholly fails to pay B, B's claim against A does not revive, for the reason that A's debt to B was wholly discharged; and this is reasonable, because C's debt to A was wholly discharged, and therefore A would have no claim over on C, if he, A, were obliged to pay his original debt to B.

NOVEL (It. *novella*), a prose fiction, a narrative of a series of fictitious events, connected by a plot, and involving descriptions of scenes and portraiture of character. Its contents, being products of the imagination, are poetical; its form is narrative. Its excellence, like that of an epic or drama, lies in the apprehension and truthful exhibition of the course of human things. As usually regarded, it is the latest stadium of the epic, heir to its dignities and subject to its æsthetic code, and may bear the title of the prose epic of contemporary life. Unlike that, however, it illustrates the transient features rather than the fundamental characteristics of an age, private and local more than historical events, and the phases of society rather than the genius of a religion or civilization. Goethe thus distinguishes the novel from the drama: "In the novel, sentiments and events are chiefly to be represented; in the drama, character and actions. The hero of the novel must be passive, at least not in a high degree active; but the dramatic hero must act; every thing resists him, and he overcomes the hindrances or succumbs." The mediæval romances of chivalry abound in preternatural marvels; most of the earlier novels sought to escape in some measure from the ordinary limits of actual life by adopting for their themes travels, duels,

elopements, adventures with banditti, or events of past history; but the novel now in vogue is mainly occupied with depicting and analyzing familiar social phenomena. A philosopher of the last century conceived that whenever the economy of municipal arrangements should be so perfected as to prevent all contraband trading and highway robbery, and so vigilantly detective as to sketch not only the physiognomy but also the biography of every traveller on his passport, romance writing would become obsolete from the absence of the necessary materials. Yet novels are now produced in unprecedented numbers, and without dependence on such elements for their success. (The essential requisite, to which all other qualities are incidental, is that they be interesting as stories, since their aim is to amuse, or at most to instruct by amusing. They have no strict artistic form, being in turn narrative, descriptive, didactic, and lyrical; may be designed to illustrate any idea, phase, or tendency of modern life; and may introduce and discuss the problems of morals, religion, philosophy, politics, history, art, literature, and science.—Romances have existed from immemorial antiquity among the principal nations of the East. The Chinese have in their oldest literature parables, marvellous fictitious narratives, and epopees; and for many centuries they have had novels of familiar and social life comparable to those of Europe. They only among the Asiatic nations have delineated in their novels the phenomena of common and domestic life, recounting the conversations, cares, and habits of the household, without intermingling unreal marvels. The play of the passions, the conflicts of interest, the constraint of moral habits, and the analysis of sentiments are the usual themes of both the Chinese novel and drama. By their names as well as characters the heroes might pass for ordinary inhabitants of Canton or Nankin. They abound in detailed descriptions, are remarkable for the beauty of their images and epithets, and are among the best sources of information concerning the private life of the people. Among their classic romances are the "Four Great Marvels' Books," and the "Stories of Pirates on the Coast of Kiang-nan." The romance of the Hindoos is perhaps of equal antiquity, but consists chiefly of fantastic and marvellous narratives. The scenes are in abysses of the sea, on perilous mountain heights, or in vague imaginary spaces. There are princes contending with giants, princesses stolen away by genii, metamorphoses, and magical talismans. Their traditions and even their histories are disfigured by their love of the marvellous, and abound in extravagant fictions. Many of their parables and fables are designed to convey philosophical and religious doctrine. The character of Hindoo fiction has made some scholars suppose that the Persian and Arabian tales were originally derived from India. During the present century several Chinese and

Indian novels have been translated into European languages. The Arabian tales of the "Thousand and One Nights" are examples of romantic fiction, highly esteemed in Europe, the recital of which is still more fascinating and general among the people of the East than is the perusal of printed novels among the western public. Excepting Xenophon, whose *Cyropædia* resembles a historical romance, the principal Greek writers of prose fiction were Heliodorus, Achilles Tatius, and Longus, all of whom lived after the 3d Christian century. The story of the loves of Theagenes and Chariclea by Heliodorus, a Christian bishop in Thessaly, was written in a pure and elegant style, and became the model of subsequent Greek romances. Achilles Tatius also recounted the adventures of two lovers, Leucippe and Clitophon. The "Daphnis and Chloe" of Longus is a pastoral romance, containing fine descriptions of scenery on the island of Lesbos. The Milesian fables and the romance attributed to Diogenes Antonius have not been preserved. The romance rapidly degenerated, and its later and worst specimens in Greek were the love stories of "Chariton and Aphrodisias," of "Chaireas and Callirhoe," of "Anthia and Abrocomas" by Xenophon of Ephesus, and of "Hysminias and Hysmine" by Eustathius. Prose fiction had appeared in Latin in the 2d century in the *Satyricon* of Petronius and the *Metamorphoseon*, or "Golden Ass," of Apuleius, which are its only noteworthy examples. Most of these classical romances relate the adventures of lovers, carried away by pirates or otherwise separated, witnessing rites of magic and religion, secret orgies, and infamous revelries in the cities on the Mediterranean coasts, and at last reunited by extraordinary coincidences. They were however neither so numerous nor so highly reputed as to form an important part of the literature. In the 8th century appeared in Greek the ecclesiastical romance of "Barlaam and Josaphat," by St. John of Damascus, perhaps translated from the Syriac.—The first mediæval romances were metrical. Whether their materials and spirit were borrowed from Scandinavia and northern Germany, especially through the Normans, or from the East through the Spanish Moors and crusaders, or whether they were relics and products of the ancient Celtic genius, are questions not yet determined. But it is certain that they were cultivated by the troubadours of Provence and the trouvères of Normandy from the 11th century. Narrative poetry soon abounded throughout feudal Europe. The wandering minstrels, under divers names, invented, translated, and amplified stories in order to satisfy the demand of the households alike of lords and peasants, rehearsing known facts and genealogies, transforming chronicles and legends into romances of chivalry, reproducing from classic history Alexander as a knight errant and Virgil as a powerful magician, adapting Byzantine tales, and devising facetious and scandalous narratives

of real life. The romances of chivalry introduced knights whose enterprise, virtues, martial achievements, and sentiments of honor and delicacy were carried to an extravagant and fabulous perfection, who became the exemplars of ideal knight errantry in the 14th and 15th centuries. The transformation of the metrical into prose romances was in part owing to the invention of printing, the advantage of metre for purposes of recital being thus superseded, and in part to the natural evolution of prose forms out of metrical beginnings, as had taken place in the history of classical literature. Prose fictions, however, celebrated Arthur, Charlemagne, and the other heroes of chivalry, and were as tedious and artless as their predecessors, though they were composed with greater regard to probability, and began to picture manners instead of being mere rhapsodies of feats of battle. In the prose narratives of "Lancelot of the Lake" and of "Pierceforest" are found minute and truthful accounts of tournaments, feasts, and other chivalric displays. The lord de la Noue (1587) thus mentions the taste for these romances: "The ancient fables whose reliques doe yet remain, namely, 'Lancelot of the Lake,' 'Pierceforest,' 'Tristram,' 'Giron the Court-cous,' and such others, doe beare witness of this olde vanitie; herewith were men fed for the space of 500 yeeres, untill our language growing more polished, and our mindes more ticklish, they were driven to invent some novelties wherewith to delight us. Thus came y^e bookes of Amadis into light among us in this last age. But to say y^e truth, Spaine bred them, and France new clothed them in gay garments." Notwithstanding the opposition made to them, the romances of chivalry did not sink into disrepute until the customs of chivalry became obsolete and were thrown into ridicule and contempt by Cervantes. Scandinavia abounded in legendary romances, both in prose and verse, on national subjects, as the *Omeyyinga Saga*, the *Heimskringla*, the *Eyrbyggja Saga*, and the more imaginary legends of the *Nibelungen* and the *Volsungen*. They have a bold, vigorous, and gloomy character peculiar to themselves. At a later period the themes of French and English romance, as Sir Tristram, Sir Percival, and Sir Yvain, were borrowed and modified by the North. Germany also had a peculiar cycle of heroes derived from her own traditional history as heir of the Roman empire, such as Theodoric, king of the Goths (Dietrick of Bern), celebrated by the minnesingers, Attila (Etzel), king of the Huns, and Günther, king of Burgundy. Many Teutonic heroes also are celebrated in the *Heldenbuch*. The German romances are of a more fierce and unrefined character than the French, from which they also differ in freely employing the preternatural and magical arts of the subterranean Duerger or dwarfs. The Gothic romance was little cultivated by the Italians. They adopted from the French the tales of

Charlemagne and his paladins, which, however, attracted little attention till Boiardo, Berni, Pulci, and Ariosto made them the basis of poems that were diffuse and rambling in style, yet far superior in regularity and beauty of diction to the earlier romances. These romances had been known for two centuries in France before they were introduced into Italy. Of the Spanish group "Amadis de Gaul" is the head and type. The story of the Holy Graal is essentially religious; that of Charlemagne is essentially military; and both relate to historical events. But the "Amadis," says Ticknor, "is of imagination all compact." Its chronology and geography are alike unsettled and uncertain; it has no purpose except to illustrate the virtues of a perfect knight; and its variety in style and topics is superior to that of other similar works. It is by general consent the best of all the old romances of chivalry. The story culminates in the marriage of Amadis with Oriana, the valor of the hero and the constancy of the heroine triumphing over the thousand obstacles interposed by rivals, giants, sorcerers, and other hostile powers. "Amadis" was succeeded by "Palmerin of England," and each was the parent of a long series, for which an unexampled passion prevailed in Spain during the 16th century. The "Don Quixote" is at once a proof of their vast popularity and a monument of their overthrow. This class attained its highest perfection in France, and the originals of the majority of romances were in French, which was then the court language of England. The legends concerning Arthur and his circle of knights were formed by the Norman minstrels from Breton lays, and from the origin of the romances they rivalled those of Charlemagne in popularity both in France and England. There are few original compositions in old English metrical romance. The *Morte d'Arthur*, compiled by Sir Thomas Malory, is the finest relic in prose (1485). This body of Arthurian legend has served as a magazine of subjects and suggestions to some of the greatest English poets from Spenser to Tennyson. —The *Decamerone* of Boccaccio consists of short stories (*novelle*), which follow the mediæval *fabliaux*, or facetious tales of real life, instead of the longer romantic narratives. They are novels of gallantry, collected from various sources, and invested in a charming style; and they present a peculiar form of finished prose fiction, which was continued by Sacchetti, Cinto, Grazzina, Firenzuela, Bandello, and others. In the 15th century the romances of chivalry had run their course in France, but the *fabliaux* or novelettes of love intrigue, like those of Boccaccio, remained. These were varied by an original and still almost unique example of the fiction of satiric humor in the works of Rabelais. The pastoral romance introduced into Italy in the *Arcadia* of the Neapolitan Sannazzaro was previously much cultivated by the Portuguese poets, and was naturalized in Spanish prose by Montemayor, whose "Diana" was

nearly as much celebrated and imitated as the "Amadis." The "Arcadia" of Sir Philip Sidney blends pastoral with chivalrous manners, is remarkable for its ideality, and indicates the transition to the romances of conventional love and metaphysical gallantry, tedious from their length and insipidity, a prominent example of which is the *Astrée* of D'Urfé (1610). The reigning quest after increased dignity and artifice of style appears in its extreme in the "Euphues" of Lilly. Gomberville, Calprenède, and Mlle. Scudéri continued this species, which was highly esteemed in France through the 17th century, though now nearly forgotten. It combined modern ideas of courage, courtesy, and fidelity with stories of ancient Greeks, Egyptians, Babylonians, and Persians, in prolix works of many volumes each. The earl of Orrery attempted in his "Parthenissa" to naturalize it in England. Its counterpart was produced by the poet Scarron in the *Roman comique*, which detailed a long series of adventures as low as those of *Le grand Cyrus* were elevated. The picaresque novel had been raised into vogue by the *Lasarillo de Tormes* of Mendoza (1575), of which many imitations appeared in the literature of Spain and other countries. Thus early in the 17th century prose fiction in most of its leading types, as the short amusing story of gallantry, the romance of enchantment and heroic chivalry, the pastoral romance, the riotous satire, the picaresque and the philosophical novel, had become an established form of literature in the principal languages of Europe.—The more complete development of the novel in England was nearly contemporary with the decline of the tragic drama. It aimed to perform for a refined and reflecting age the service which had been rendered by the drama to a ruder and more chivalric period. As the wilder passions and impulses of society became more restrained, the narrative style was called into vogue to give an even and detailed development of sentiment and incident. Though incapable of so powerful an effect as tragedy, novels have the advantage of a wider license in the conduct of the plot, of fuller descriptions and more minute characterizations. Contemporary with the comic dramatists, who substituted conventional wit, maxim, and sentiment for passion, Mrs. Behn produced tales which justified the sarcasm of Steele that she "understood the practical part of love better than the speculative;" and her successors and imitators, Mrs. Manley and Mrs. Haywood, indicate a like reaction from the stilted and extravagant character of the older romances to the topics and personages of real life. The only English prose fictions of the time marked by high poetic ideality were Bunyan's allegories of the "Pilgrim's Progress" and the "Holy War." The modern novel began in England with Defoe and Swift. The graphic details of the career of Robinson Crusoe have rarely been excelled in verisimilitude. The work has also the charm of emancipating the reader from the haunts of ordinary society,

and introducing him with consummate skill to the reflections and incidents of a struggle for life on a desolate island. The effect of this and the other fictions of Defoe (one of which, the "Memoirs of a Cavalier," was taken by the earl of Chatham for a true history) is caused by the vivid delineation and concatenation of practical details, which give to the adventures the force of realities commanding the interest and sympathy of the observer. The series of Arthurian, Utopian, and Arcadian romances, and the novel of French and Italian gallantry, had thus been succeeded by a work marked by all the severity and apparent probability of history. The satirist of the age was Swift, whose prototype, if he had any, was Rabelais, and whose "Gulliver's Travels" are equally interesting whether read with or without reference to the allegorical and satirical meaning. The novel was improved by its three great masters, Richardson, Fielding, and Smollett, who presented the passion of love according to its action amid the improved manners, the complicated and artificial distinctions introduced by wealth and luxury, the contrast between town and country, and the real aspects and interests of ordinary life. Though the novels of Richardson are of great length, their accumulation of minute lights and shadings, their profound knowledge of human sentiments and passions, and the earnestness with which they enlisted the passions on the side of virtue, made them an immense advance on all their predecessors. "It requires a reader," says Sir Walter Scott, "to be in some degree acquainted with the huge folios of inanity over which our ancestors yawned themselves to sleep, ere he can estimate the delight they must have experienced from this unexpected return to truth and nature." Yet they incurred the criticism of D'Alembert, *La nature est bonne à imiter, mais non pas jusqu'à l'ennui*. Richardson excelled especially in his female characters, his "Clarissa Harlowe" being his noblest tribute to feminine purity. The novels of Fielding indicate a less sentimental tendency, are less marked by delicacy of perception and command of pathos, and more by flow of animal spirits, vivacity of manner, sagacity in grasping and skill in epitomizing characters, and thorough knowledge of the better and worse features of English life. The plot also of his masterpiece, "Tom Jones," is admitted to be of unequalled perfection, the thread of interest being all made to bear upon the catastrophe; and the whole work reveals his versatile, humorous, and adventurous genius. He makes the novel include wit, love, satire, humor, observation, and wisdom. In contrast with Fielding was Smollett, who delineated rather the eccentric than the common features of character, dealing in humorous exaggeration, inventing burlesque personages, incidents, rencontres, and oddities of speech and action. His characters are generally caricatures and his scenes extravagant. His humor is rather farcical than

comic, and yet he rarely fails in his aim to excite laughter. His works were in their time perhaps the greatest triumph in the art of literary entertainment. Dr. Johnson maintained that Fielding and Smollett painted chiefly "characters of manners," while Richardson painted "characters of nature." The "Tristram Shandy" of Sterne offers a phase of humor differing from that of either of his contemporaries, and almost unique in English literature. The book has little plot or continuous action, its interest depending on its personages and sentiments, and its humor arising from the quiet and almost unconscious development of secrets of character. It follows the theory that "a plot is good for nothing except to bring in good things," and it abounds in felicities of diction, subtleties of insight, and in tenderness and pathos which are sometimes melodramatic. These four great novelists of the reign of George II. were succeeded by inferior but unequal imitators. Among the best productions were the "Rasselas" of Johnson, the "Vicar of Wakefield" of Goldsmith, the "Castle of Otranto" of Walpole, the "Old English Baron" of Clara Reeve, the "Fool of Quality" of Henry Brooke, the "Man of Feeling" and "Man of the World" of Mackenzie, the "Evelina" and "Cecilia" of Madame d'Arblay, and the oriental romance of "Vathek" by Beckford. These productions were not sufficient to support the dignity of this species of literature, and a mass of worthless productions were issued from the Minerva press and widely distributed by circulating libraries. Charles Lamb describes the heroes as "persons neither of this world nor of any conceivable one; an endless string of activities without purpose, of purposes without a motive." Absurd in plot and characterization, weak in conception and execution, and ridiculous from their sentimentalism, they were nevertheless read with avidity by both sexes in the higher spheres of life. A different tendency, prompted perhaps by the Gothic romance of Walpole, appeared in the fictions of Mrs. Radcliffe, Matthew Gregory Lewis, and some of those of the Misses Porter. Mrs. Radcliffe is the chief of these practitioners in picturesque horrors and vague perils, in adventures by night, in storm and solitude, in ruined castles with wild banditti, while half-heard sounds and glimpses of visions haunt the imagination. A stricter realism was manifested by Miss Edgeworth and Miss Austen, who described domestic life with minuteness, good sense, a clear moral aim, and charming simplicity of style. During the era of the French revolution, a tendency to embody social speculations and aspirations in fiction appeared especially in the works of Bage and Holcroft, and in the "Caleb Williams" of Godwin. Such was the condition of British novel writing when the author of "Waverley" became its unrivalled head. The Minerva press not unequally disputed the field of popularity and success with the best productions of his immediate predecessors.

Scott may be said to have created the historic romance as a new department of English literature. His retrospective cast of mind, genial sympathies, historic sagacity, and creative imagination enabled him to give a vivid and truthful reproduction to past characters, manners, thoughts, and passions. He raised a higher standard of novel writing than had been before known, and substituted for the vapid sentimentalism and inane extravagance which had been in fashion, good sense, genuine humane feeling, power and beauty of description, and life-like impersonations both of manly and womanly character in all ranks from the throne to the cottage. Notwithstanding his preëminent success, it is alleged by Ruskin and Bunsen that he did not truly understand the feudal and chivalrous times which he represents in some of his novels, and that his vivid scheme of mediævalism and feudalism was essentially false. Since Scott the British novelists are the most numerous class in the list of authors. In the year 1820, when the Waverley series was at the height of its popularity, the British museum added but 26 novels in 76 volumes to its library; in 1830, it added 101 novels in 205 vols.; in 1850, 98 novels in 210 vols.; in 1856, 88 novels in 201 vols. Thus from the time of Scott's death, the yield of nearly 100 novels every year, or 2 every week, appears to have continued constant. An average calculation from these data indicates that the British islands have produced about 4,500 novels in about 10,000 vols. since the publication of "Waverley;" and this estimate is confirmed by the London book catalogue, in which the novels published in Great Britain from 1816 to 1851 inclusive amount to 3,300 separate entries. Mr. Masson makes the following classification of this mass of literature, exclusive of Scott's works: 1, the novel of Scottish life and manners, represented by Galt, Mrs. Johnstone, Miss Ferrier, Hogg, Allan Cunningham, Lockhart, Wilson, Sir Thomas Dick Lauder, Picken, and Moir; 2, the novel of Irish life and manners, initiated by Miss Edgeworth, and developed by Lady Morgan, Banim, Crofton Croker, Griffin, Carleton, Lover, Lever, and Mrs. S. C. Hall; 3, the novel of English life and manners, representatives of which are Lady Caroline Lamb, Peacock, Theodore Hook, Plumer Ward, Disraeli, Bulwer Lytton, Mrs. Gore, Mrs. Trollope, Lady Blessington, Miss Martineau, Warren, Douglas Jerrold, Mrs. Crowe, Miss Jewsbury, Lewes, Shirley Brooks, Mrs. Marsh, Miss Mulock, the Brontë sisters, Mrs. Gaskell, Kingsley, Dickens, and Thackeray; 4, the fashionable novel, represented by several of those in the preceding list; 5, the illustrious criminal novel, as Bulwer Lytton's "Paul Clifford" and Ainsworth's "Jack Sheppard;" 6, the traveller's novel, as several of those of Bulwer Lytton, Mrs. Gore, and Mrs. Trollope; 7, the novel of American manners and society, of which Mrs. Trollope, Marryat, Dickens, and Thackeray have given specimens; 8, the oriental novel, as the Persian and Indian

fictions of Morier and Fraser; 9, the military novel, represented in the stories of Gleig, Maxwell, and Lever; 10, the naval novel, as those of Marryat, Ohamier, Hannay, and Cupples; 11, the novel of supernatural phantasy, as Mrs. Shelley's "Frankenstein," Bulwer Lytton's "Zanoni," and some of Douglas Jerrold's tales and of Dickens's Christmas stories; 12, the art and culture novel, the highest attainments in which have been made by Bulwer Lytton; 13, the historical novel, represented by James, Ainsworth, Horace Smith, Bulwer Lytton, Hope, Lockhart, and Kingsley. This classification, however, leaves strangely out of account the religious novel, perhaps at the present day the most widely circulated of all, of which Mrs. Sherwood, Hannah More, Miss Sewell, Miss Yonge, and Miss Warner have produced the most remarkable specimens. Sir Bulwer Lytton has made a simpler classification, not according to the matter but to the style of treatment, into the three kinds of familiar, picturesque, and intellectual novels. Many novels have been written with an avowed didactic aim, to inculcate or satirize political and ecclesiastical movements, and nearly every question or doctrine publicly agitated has one or more romances written to support or assail it. Among recent fictions, "Adam Bede" and "The Mill on the Floss," by Miss Evans, are remarkable for their realistic tendency.—In American literature, novels appeared later than histories, poems, and works of travel and didactic discussion. Even satire had flourished long in verse, before it assumed the form of prose burlesque narrative. It was not till after the revolution, and till nearly the time of Miss Edgeworth and Sir Walter Scott, that the earliest attempts were made in prose fiction. The first noteworthy American work in this style was "The Foresters, an American Tale," by Jeremy Belknap, first published in successive numbers of the "Columbian Magazine" in 1792. The foresters were personifications of the leading American states and interests, with names that could readily be interpreted, and the narrative embodied much of the history of the revolution and of the formation of the confederation. The poet Bryant describes it as "a work which sought to embellish our history with the charms of wit and humor." John Witherspoon's "History of a Corporation of Servants, discovered a few years ago in the Interior Parts of South America," is a satirical romance, treating under a disguise the ecclesiastical history of Great Britain. The next novel was "Modern Chivalry, or the Adventures of Captain Farrago, and Teague O'Regan, his Servant," by Hugh Henry Brackenridge (1st vol., Pittsburgh, 1796; 2d vol., 1806). It is modelled after "Don Quixote," gives proof both of scholastic reading and rough adventures in the West, and is a curious delineation of the social and political humors of the time. The "Algerine Captive, or the Life and Adventures of Doctor Urdike Underhill, Six Years a Prisoner

among the Algerines," by Royal Tyler (Walpole, 1797), is a medley of narrative, criticism, and statements of opinion on topics of American society, the slave trade, Algerine grievances, and Mohammedanism. It was mistaken by an English critic for a genuine history. Mason L. Weems wrote several short tales of horror in illustration and denunciation of the crimes prevalent in the wild regions of the South. Soon afterward appeared "Female Quixotism, exhibited in the Romantic Opinions and Extravagant Adventures of Dorcasina Sheldon," by Mrs. Tabitha Tenney. The heroine is crazed by reading innumerable sentimental novels of the Rosa Matilda school, and engages in a series of romantic adventures. Charles Brockden Brown is usually styled the first American novelist. He produced about the beginning of the century 6 novels in rapid succession, the best of which, as "Wieland," "Arthur Mervyn," and "Edgar Huntley," were popular in America and reprinted in England. They resemble the romances of Godwin, depend for their interest rather on the development of an idea than the exhibition of character, treat more of adventure in the wilderness than of indoor scenes, and consist almost entirely of narrative uninterrupted by dialogue. Charles Caldwell, one of the editors of the Philadelphia "Portfolio," wrote a Persian story entitled "Bachtiar Nameh, or the Royal Foundling." William Dunlap published in 1836 his novel of "Thirty Years Ago, or the Memoirs of a Water Drinker," recounting events in the life of George Frederic Cooke and other actors contemporary with him in New York. More important than any similar works that had preceded them were the satirical and humorous novels of James K. Paulding, the most successful of which was the "Dutchman's Fireside," treating the character and customs of the Dutch settlers of New York, which passed through 6 editions within a year, was republished in London, and translated into French and Dutch. Among the writings of Washington Irving, his associate in the authorship of "Salmagundi," are numerous short tales, but none of them can properly be called novels. For many years James Fenimore Cooper was esteemed the greatest American novelist. His novels were published at intervals from 1821 to 1850, and describe life both at sea and on land. The best of them are "The Spy," "The Red Rover," "The Pilot," and the Leatherstocking series, in which a single character is reproduced in different ages of his career, associating and warring with the aborigines, retreating before advancing civilization, and leading a savage life with the spirit of a philosopher. They deal with the peculiar characters and scenery of America, with Indians and pioneers, and have therefore been particularly esteemed by Europeans. William Gilmore Simms is, after Cooper, the most voluminous American novelist. His scenes are chiefly in the southern states, and several of his

romances are founded on events of Indian and revolutionary history. He excels in vivid and rhetorical description. The novels of Nathaniel Hawthorne display a peculiar and powerful genius. In delicacy and intensity of psychological characterizations, in mastery of the emotions of guilt and insight into the sterner qualities of the New England people, and in richness and precision of style, he has no superior. The most extensively popular work of fiction ever produced in any country was the "Uncle Tom's Cabin" (1852) of Harriet Beecher Stowe, which within a year was translated into all the languages of Europe. How far its success was due to artistic merit, and how far to the interest taken in the subject which it treated, has been a matter of dispute among critics. Among other novels issued between the successes of Paulding and Mrs. Stowe are the powerful tales of Richard H. Dana, contained in the "Idle Man;" the Italian romance of "Monaldi," by Allston; graphic stories of western life and adventure by Flint, Hall, and Mrs. Kirkland; "Horseshoe Robinson," "Swallow Barn," and "Rob of the Bowl," delineations of western and southern scenery and history, by J. P. Kennedy; Dr. Bird's Mexican romances; sketches of New York society, by Hoffman and Cornelius Matthews; William Ware's reproductions of classical and early Christian history in "Zenobia," "Probus," and "Julian;" Mrs. Child's Greek tale of "Philothea;" Judd's "Margaret," the best of his stories of New England life; the earlier and more effective novels of John Neal; the satirical "Peter Schlemihl in America" of George Wood; the "St. Leger" of Richard B. Kimball; the "Lady Alice" and "Alban" of J. V. Huntington; and the domestic tales of Miss O. M. Sedgwick, Maria J. McIntosh, Mrs. L. H. Sigourney, Elizabeth Oakes Smith, and the Misses Warner. They have since been published in unprecedented numbers, in many cases anonymously, often obtaining a large though ephemeral sale. One of the most successful was the "Lamplighter," by Maria Cummings. Other popular novelists are Caroline Chesebro', Mrs. Emma D. E. N. Southworth, Caroline Lee Hentz, Ann S. Stephens, Augusta J. Evans, and the writer under the pseudonym of Marion Harland. The "Professor's Story," by Oliver Wendell Holmes, is an admirable and peculiar development of this species of literature, in which the plot yields in importance to characterization and philosophic and humorous monologue. "The Bay Path" and "Miss Gilbert's Career," by J. G. Holland, are spirited delineations of New England character and history, while the "Trumps" of G. W. Curtis treats of society in New York.—In France, the reign of pastoral and heroic romances was succeeded by an inundation of oriental tales, *contes des fées*, and *voyages imaginaires*, the principal writers of which were Perrault, the countess d'Aulnoy, Galland (who translated the "Arabian Nights"), Petit de la Croix, and Le Sage. This species of litera-

ture was burlesqued in the fairy tales of Count Hamilton. The greatest French novelist of the 18th century was Le Sage, whose *Gil Blas* has perhaps been only less widely popular than "Don Quixote," and has been affirmed to contain more useful knowledge than 20 scientific and moral treatises. "It is a work," says Scott, "which renders the reader pleased with himself and with mankind; where faults are placed before him in the light of follies rather than vices; and where misfortunes are so interwoven with the ludicrous that we laugh in the very act of sympathizing with them. All is rendered diverting, both the crimes and the retribution which follows them." Nearly contemporary with him were Marivaux, one of the first to abandon romantic extravagance, but whose style is intolerably tedious and affected; Prévost, who gave a tragic gloom and grandeur to his novels; Mme. de Tencin, authoress of tender and delicate love stories; the younger Crébillon, who, according to D'Alembert, "draws with a graceful and just pencil the refinement, the shades, and the graces of our vices;" Voltaire, whose novels were designed with gay irony to illustrate and enforce opinions; and Rousseau, whose eloquent romances of *Julie* and *Émile* contain his theories of love, society, education, and religion. The degeneracy of French society appears in the coarser and feebler novels of Louvet, La Clos, and Restif de la Bretonne. A better taste begins with Bernardin de St. Pierre, and was maintained by Châteaubriand, Mme. Cottin, and Mme. de Staël. The principal subsequent French novelists are Frédéric Soulié, Victor Hugo, Balzac, Alexandre Dumas, father and son, George Sand, Alfred de Vigny, Alphonse Karr, Vitet, Mérimée, Paul de Kock, Eugène Sue, and About. A species of physiological romance, forming what has been called *la littérature brutale*, has recently been brought forward by Flaubert and Feydeau. The French romantic literature of the present century, though displaying remarkable ability, abounds in strange conceits, wild suggestions, extravagant scenes, and overwrought sentiments.—In Spain no book of chivalry was written, and few were reprinted, after the appearance of "Don Quixote" in 1605. This work failed of disappearing with the romances which it exploded, in consequence of its deeper idea of the contest between imagination and reality. Its two characters, one a lofty but crazed idealist, the other a sturdy materialist, wander together in quest of adventures. The former transforms windmills into giants, inns into castles, and galley slaves into oppressed gentlemen; while the latter with unconscious humor translates them all into the plain prose of truth. The story combines the extremes of the lofty and the vulgar, the pathetic and the ludicrous, in human life. Prose pastorals were the first to succeed the romances of chivalry, as in other countries, and were themselves supplanted by tales in the *gusto picaresco*, or in the style of

rogues. Grave and historical fiction did not appear with noteworthy merits till the reign of Philip II., the first proper historical romance being Hita's "Civil Wars of Granada," which contains admirable delineations of the manners and ceremonies of the time. The tendency of such works, however, to represent the Moors in romantic and attractive colors never met with favor in Spain, and from the reign of Philip IV. historical fictions almost disappeared for more than a century, and never afterward obtained high renown. But short stories or tales were more popular in the 16th and 17th centuries, and seem to have been of native origin and little affected by oriental or Italian influences. Villegas, Timoneda, Figueroa, Baredillo, and many others cultivated this style with success. The *Cigarrales de Toledo* (1624), by Tellez, was the first of numerous collections of stories recited at or pertaining to social entertainments. Allegorical or satirical tales were common, the best being those of Santos (about 1700). Romantic fiction in Spain was alike remarkable for its early splendor and its early decay. It was at the height of its glory before the age of pastoral romance in other countries; and from the time of its decline it has been of little account, though translations of the best foreign novels are highly esteemed.

Italy has been unsurpassed in the number of her novelists. From Boccaccio to Gozzi (1818-1786) the Italian novels were only short tales of gallantry or comic adventure, with little development of plot, character, or sentiment, written in an affected and pompous style. Bandedello, Ointio, and Macchiavelli (*Belphegor*) are almost the only names of special note. Several longer tales were produced near the close of the 18th century, only one of which, the *Ultime lettere di Jacopo Ortis*, by Ugo Foscolo, attained high repute. It is an imitation of Goethe's *Werther*, the author bewailing at once his misfortunes in love and the calamities of his country. The best Italian romance is the *Promessi sposi* of Manzoni, admirable for its simplicity and vivacity. Rosini, Oantu, Grossi, Tommaseo, Belmonte, Azeglio, Guerrazzi, and Bersezio are the principal subsequent novelists. The scenes of many of their productions belong to mediæval Italian history.—German prose fiction had little that was original or peculiar till the latter part of the 18th century. The principal cycle of earlier romances were the numerous imitations of "Robinson Crusoe," of which *Die Insel Felsenberg* was the best. Historical romances, novels of real life, novels marked by particular tendencies respecting art, literature, or society, and especially imaginative and poetical tales, have been common since the revival of this literature about the time of Goethe and Schiller. The romances of Wieland, though diffuse and didactic, were admired for their semi-Greek, semi-Parisian tone. August Lafontaine succeeded in sentimental descriptions of common and domestic life; Wetzel, Müller, Schulz, and Hippel illustrated

the comic side of family trials and joys; and Richter endeavored to combine the English humor of Sterne with German sentiment, and is remarkable for his rich and eccentric style. Tieck, Fouqué, Hoffmann, Brentano, Chamisso, Apel, and Arnim were the principal novelists of the romantic school, who availed themselves of mediæval legends and mystical views. Chivalric romances were revived by Oramer, Spiess, Schlenkert, and Veit Weber, who rivalled Mrs. Radcliffe in the enginery of terror. Popular legendary tales (*Volkemärchen*) constitute a special department of German fiction; and while the romantic school treated the traditional groundwork with earnestness and apparent belief, Musäus employed it only for purposes of drollery or of fanciful and grotesque description. The novels of Heinse aim to invest sensuality with the graces of art. The *Wilhelm Meister* of Goethe is the most eminent example of the art and culture novel, with great merits at least for its ingenious speculations on the highest topics of literature and art. Among female novelists Fanny Tarnow, the baroness de la Motte-Fouqué, Johanna Schopenhauer, Henrietta Hanke, the countess Hahn-Hahn, and Caroline Pichler are prominent. The novels of Kruse are at the head of a class of *Kriminal-Geschichten*, the plot consisting in the discovery of guilt by circumstantial evidence. The *Michael Kohlhaas* of Kleist is a remarkable historical romance, and according to Goethe "brings prominently into view a dissonant principle in nature, with which poetry ought not to meddle, with which it cannot reconcile itself, let the handling of the matter be never so exquisite." Other historical romancers were Von Tromlitz, Spindler, König, Mügge, and the Norwegian Steffens. Among contemporary novelists, Auerbach, Gutzkow, and Freytag are preëminent for their delineations of society in its real and living features; the historical romance is best represented by Wilibald Alexis (Wilhelm Häring); and Gottfried and Johanna Kinkel excel in the department of brief and humorous tales.—Among the most important novels in other languages are those in Danish by Hans Christian Andersen, and in Swedish by Fredrika Bremer and Madame Carlen.—See Dunlop, "History of Fiction" (3d ed., London, 1848); Wolff, *Allgemeine Geschichte des Romans* (2d ed., Jena, 1850); and Masson, "British Novelists and their Styles" (London and Boston, 1859).

NOVELLO, OLARA ANASTASIA, Countess Gigliucci, an English singer, born in London, June 10, 1818. She is a daughter of Vincenzo Novello, an English musical composer of Italian descent, born in London in 1781, whose compositions, particularly those of sacred music, enjoy a high reputation. She completed her musical education in Paris, and made her first public appearance at a concert in Windsor in 1833. Mendelssohn-Bartholdy invited her to spend some time at Leipzig, and she also gave performances in Berlin, Vienna, and St. Peters-

burg; and, after having performed in opera at Padua as Semiramis, and in other Italian cities, she appeared on her return to England in 1843 as prima donna in the Drury Lane theatre, and has since remained a great favorite in English operas and concerts. In 1848 she married Count Gigliucci, and resumed her performances in 1850. From 1854 to 1857 she was attached to La Scala at Milan, and made her last public appearance in London, Nov. 21, 1860, on retiring to private life.

NOVELS (*Novella Constitutiones*). See CIVIL LAW, vol. v. p. 275.

NOVEMBER (Lat. *novem*, nine), the 11th month of our year, and the 9th of the Roman when their calendar was first founded. It was one of the 10 months of the year of Romulus, and consisted originally of 30 days, which number was afterward changed to 29, probably by the decemvirs. Julius Cæsar gave it 31, but Augustus restored it to its original number. By the heathen Saxons it was called Blot-month, because in this month they sacrificed to the gods the cattle that they slew. It corresponds to parts of Marhehvan and Kisleev of the Hebrew calendar, and to the end of Brumaire and the greater part of Frimaire of the French revolutionary calendar.

NOVGOROD, a N. W. government of European Russia, bounded by Olonetz, Vologda, Jaroslav, Tver, Pskov, and St. Petersburg, between lat. 57° and 62° N., and long. 80° and 40° E.; area, 46,833 sq. m.; pop. in 1856, 812,454. It is divided into 10 districts, and contains, beside the capital of the same name, the towns of Staraya Russa, Valdai, and Tikhvin. The principal rivers are the Msta, which enters the government from Tver, flows N. W., and falls into Lake Ilmen; the Lovat and Pola, which fall into the same lake; the Volkhov, which flows from that lake into the Ladoga canal; the Sheksna and Mologa, tributaries of the Volga; and the Sias and Busha, which fall into Lake Ladoga. There are 8 large lakes, of which the most extensive are the Bielo Ozero (white lake) in the N., about 25 m. long and 20 m. broad, and Lake Ilmen in the S. W., 26 m. long and 16 m. broad. In the S. W. the Valdai hills enter from the province of Pskov, and stretch N. E. They are a limestone range, nowhere more than 1,000 feet high. The surface of Novgorod is covered with an immense number of granite boulders, though there is no granite *in situ* within the province, nor in any of those immediately adjoining. The face of the country is in general flat, a considerable portion of it being covered with lakes and marshes. The soil of the N. portion is for the most part swampy and of a poor quality, but in the S. it is good and productive. The climate is cold, and the winter lasts from November to May. There are large forests of pine, fir, birch, alder, and elm. The principal crops are rye, barley, oats, flax, and hemp. The forests afford shelter to large numbers of wild animals; and the lakes and rivers are well stocked with

fish, which form a considerable article of export to St. Petersburg and Moscow. Iron, coal, and salt are found; and limestone, sandstone, and gypsum are very abundant. Manufactures and trade are both of little importance. —NOVGOROD, or NOVGOROD-VĒLIKŌI (Great Novgorod), the capital, is situated on the river Volkhov, near the point where it issues from Lake Ilmen, 103 m. S. S. E. from St. Petersburg; pop. about 19,000. It stands on a plain about 450 feet above the level of the sea, and is divided into two parts by the Volkhov, which is crossed by a fine wooden bridge supported on granite pillars. The town is generally ill built, and the portion on the right bank of the river has streets which in many places are overgrown with grass, and are nearly all unpaved. The other portion is surrounded by a rampart of earth, and contains the Kremlin, or citadel, within which is the cathedral of St. Sophia, built after the model of St. Sophia at Constantinople. There are 61 other churches, and several monasteries. The manufactures are not of much importance, and consist of sail cloth, leather, tobacco, candles, and vinegar. There is a trade in flax, corn, and hemp, carried on chiefly with St. Petersburg. Novgorod is one of the most ancient towns in Russia, and was founded in the 5th century by the Slavi, who established here the original foundation of the Russian monarchy, the seat of which was afterward removed to Kiev. In the 12th century Novgorod became an independent republic under a hereditary magistrate of limited power. The territory of this state extended as far as Siberia on the E. and Livonia on the W. It had an extensive trade; one of the earliest factories of the Hanseatic league was established at Novgorod, and its fairs were resorted to by traders from all the neighboring countries. In the 15th century the population was 400,000; but in 1477 its independence and prosperity were destroyed by Ivan Vasilievitch I.

NOVICE, a candidate for admission into a religious order who has not yet taken the vows, but is passing through a period of probation designed to try his vocation. Novices usually wear the dress of the order, with perhaps some distinguishing mark, as in certain of the sisterhoods, in which their veils are white instead of black, and are subject to the rules and the authority of the superiors. They are placed under the direction of an officer of the convent, called the master or mistress of novices, whose duty it is to examine their characters and fitness for the religious state, and to try their strength by exposing them to the most serious obstacles to perseverance which they are likely to encounter in the order. The period of probation, called the novitiate or noviceship, must be, according to the council of Trent, at least a year, and it is often longer.

NOX (Gr. Νύξ), in Greek and Roman mythology, the goddess of night, the daughter of Chaos and sister of Erebus (Darkness), and,

according to the Hesiodic theogony, one of the very first created beings. By her brother Erebus she became the mother of *Æther* and *Hemera* (Day), and is said to have given birth without any husband to *Thanatos* (Death), *Dreams*, *Momus*, the *Hesperides*, *Nemesis*, &c. In later poets she is merely the personification of the darkness of night. She is represented as a winged goddess, covered with a dark, star-spangled robe, or sometimes riding in a chariot accompanied by the stars, and holding in her arms the gods of sleep and death as two boys.

NOXUBEE, an E. co. of Miss., bordering on Alabama, and intersected by Noxubee river; area about 700 sq. m.; pop. in 1850, 16,299, including 11,323 slaves. It has a nearly level surface and an excellent soil. The productions in 1850 were 895,718 bushels of Indian corn, 96,084 of sweet potatoes, and 12,555 bales of cotton. There were 10 grist mills, 8 saw mills, 3 tanneries, 23 churches, and 894 pupils attending public schools. The Mobile and Ohio railroad passes through the capital, Macon.

NOYES, GEORGE RAPALL, D.D., an American divine, born in Newburyport, Mass., March 6, 1798. He was graduated at Harvard college in 1818, studied theology at the divinity school in Cambridge, was licensed to preach in 1822, and being appointed tutor in Harvard in 1825, remained in that office two years. He was then ordained pastor of a church at Brookfield, Mass., and afterward became pastor of a church at Petersham, Mass. In 1839 he received from Harvard college the degree of D.D., and in 1840 was chosen Hancock professor of Hebrew and other oriental languages, and Dexter lecturer on biblical literature. His services in this office have been chiefly confined to the divinity school, though for a portion of the time, in connection with other professors, he has officiated as college chaplain and preacher. His published works have been chiefly in the department of Hebrew philology, including new translations of the book of Job (1827), the Psalms, the Prophets (3 vols. 12mo.), and Proverbs, Ecclesiastes, and Canticles (1846). Dr. Noyes has also published several occasional sermons and numerous articles in the "Christian Examiner," has edited a series of theological essays from various authors, and prepared a Hebrew reader.

NUBIA, a name given to the countries on and around the valley of the Nile, between Egypt and Abyssinia on the N. and S., and the Red sea and the great desert and Nigritia on the E. and W.; pop. about 200,000. The word Nubia is very indefinitely used, however, being applied by some geographers to a much less extent of country, and even sometimes restricted to the territory E. of the Nile, while the natives call the small tract between Derr and Dongola alone Nooba, or Wady-el-Nooba. Within the limits above defined, it extends between lat. 11° and 24° N. and long. 28° and 39° E., about 850 m. in length, and rather more than 600 in breadth; it comprehends Nubia proper, or the valley of

the Nile, extending from the limits of Egypt to the S. boundary of Dongola; the ancient Meroë, the modern capital of which is Shendy, and the territory of which may be considered as extending along the Nile from Dongola to the junction of the Blue and White rivers; and Sennaar, higher up, to which seem to be annexed Kordofan and Taka. Lower Nubia consists chiefly of deserts, extending on the E. to the Red sea and on the W. almost to the great Sahara, but relieved in the valley of the Nile by mountain ranges of sandstone and granite, which approach close to the banks of the river, leaving only a narrow strip of land along the water's edge. In some places the rocks encroach upon the bed of the river and form rapids, the lowest of which, called the first cataract, occurs near the frontier of Egypt. Upper Nubia is an elevated table land, attaining toward the S. boundary a height of 4,000 feet above the sea. In this district there are several mountain chains, which, instead of running parallel to the river, stretch E. and W., one of them extending to the Red sea, and sending off numerous branches into the Nubian desert. There is also a range of hills along the coast of the Red sea, and among or near them are said to exist gold and silver, though none of the attempts to extract the ore have been successful. The chief geological formations of upper Nubia are granite, quartz, and mica slate. The country is well watered by numerous tributaries of the Nile, and above the second cataract stretches into vast and fertile but neglected plains, which it is conjectured were at some remote period reached by the inundations of the Nile. Artificial means of irrigation are now resorted to, among which is the *sakiyeh* or Persian wheel for raising the water of the river. The W. bank appears to have been anciently the principal seat of prosperity, but the E., being the more easily watered, is now more cultivated.—The climate of Nubia is very hot, but upon the whole not unhealthy. Small pox is the only epidemic of the country, the plague being hardly known. Rain does not fall in the lower district, but in upper Nubia there are plentiful showers from March to May. The principal crops are durra, barley, French beans, lentils, and watermelons. Two and occasionally three harvests are reaped in the year. Tobacco is cultivated everywhere, and is the principal luxury of the people. Animal food is seldom used. An intoxicating liquor is made from dates, and a sort of beer from durra. Though the soil is well adapted for many other kinds of fruit, palms are the only trees cultivated. The trees growing near the desert are mostly acacias, tamarisks, and date and doum palms. Cows, sheep, goats, buffaloes, oxen, and a few camels, are the domestic animals of the Nubians. In the E. mountains gazelles are found. Dongola has a fine breed of horses. Hyenas are sometimes seen on the banks of the Nile, and monkeys in the mountain ranges. Crocodiles and hippopotami are found in the Nile. Fish are taken in nets about the neigh-

borhood of the cataracts. The women weave coarse cotton and woollen cloth, and from the leaves of the date tree they form mats and bowls. These are the only manufactures, and every thing else is imported from Egypt. About 80 tons of dates are annually exported; beside which, grain, ivory, musk, ebony, leeches, coffee, and honey come from the S. and S. E. part of the country. Burckhardt calculated the number of slaves sold annually in the market of Shendy at about 5,000, of whom 1,500 are for the Egyptian and 2,000 for the Arabian market, and the rest are purchased by the Bedouins. A caravan travels twice a year from Mahass to Cairo with slaves.—The inhabitants are a handsome mulatto race, of dark brown complexion, bold, frank, cheerful, and morally much superior to the Egyptians. They live in low huts built of mud or loose stones, roofed with durra straw; the houses of a few of the larger villages are however better built. One of the most remarkable features in Nubia is the extensive monumental ruins that stand along the banks of the Nile, most of which are situated on the W. bank of the river. Some of these temples are of very ancient date, extending back to the times of the Pharaohs. About 15 m. above the first cataract are the remains of a temple dedicated, according to the Greek inscription over the entrance, by Ptolemy Philometer and his queen Cleopatra, to Isis and other deities. Some of the temples further up the river are ornamented by many columns, colossal figures, and statues of from 10 to 16 feet in height; and at one an avenue of 16 sphinxes leads from the bank of the Nile to the temple.—The name Nubia is supposed to have originated in Egypt, where the word *nub* or *nub*, signifying gold, lent an appellation to those countries whence the precious metal was brought. In the early Greek and Roman writers there is occasional mention of Nubia, but no particular information concerning it. The emperor Diocletian gave up to the Nubæ or Nubatæ a strip of land above the first cataract, on condition of their preventing the Ethiopians and Blemmyes from attacking Egypt. When the Moslems invaded Egypt in the 7th century, they found settled here a powerful Christian nation called Noubas, whose capital was at Dongola. According to an Arab writer, they consisted of two distinct races, both of which came originally from Yemen; and even at the present day two languages are spoken, though the inhabitants differ from one another in no other important particular. They remained tributary to their Arab conquerors, though frequently revolting and as often subdued, until the 14th century, when the power of the king of Dongola, who with all his ostensible allegiance to Egypt had been virtually independent, seems to have been broken; the Bedouin Arabs invaded the territory in great numbers, Christianity became extinct, and many petty Mohammedan states, among which were Sukkot, Mahass, Dongola, and Berber, sprang up, each under

its own chief. In 1821 Mehemet Ali, the pasha of Egypt, sent an expedition against Nubia, overcame the principal states, and finally extended his conquests as far as the frontiers of Abyssinia. Ever since that period the country has remained in subjection to the Egyptian pashas.

NUDIBRANCHIATES, an order of gastropod mollusks, whose gills are exposed. (See **MOLLUSKS**.)

NUECES, a S. co. of Texas, bordering on the gulf of Mexico, and bounded N. by the Nueces river; area estimated at 5,500 sq. m.; pop. in 1858, 1,916, of whom 98 were slaves. Between the mainland and the Isla del Padre, a narrow strip of land extending along the coast, is the Laguna del Madre. Corpus Christi bay is on the N. E. corner, and the county is indented by other bays and lagoons. These waters furnish fish and oysters in abundance. It has an undulating but nearly level surface, and the soil is a rich sandy loam, and very fertile. The county is excellently adapted to the raising of sheep. Capital, Corpus Christi.

NUEVO LEON. See **NEW LEON**.

NUISANCE (formerly written *nuisance*; law Fr. *noissance*, *noysaunce*, from *noier*, modern Fr. *nuire*, to injure; Lat. *nocumentum*, from *noco*, annoyance, any thing that worketh hurt, inconvenience, or damage). Nuisance cannot be well defined in specific terms. Not only are the rights which it affects themselves rather indefinite, but, including as the offence does both private and public injuries, it is applied as well to those immediate wrongs to individuals which can hardly be distinguished from trespass, as to those remote offences against the public order and welfare in which no one member of the community can show greater damage than any other. More than this, the offence of nuisance is rarely direct and aggressive, but the injury in which it consists is rather the consequential than the immediate effect of the wrong act.—A familiar division of nuisances is that into public or common and private. The former, says Blackstone, are those which affect the public and are an annoyance to the king's subjects, for which reason we must refer them to the class of public wrongs. Private nuisance may be defined as any thing done to the hurt or annoyance of the lands, tenements, or hereditaments of another, as when one projects the eaves of his own building over the roof of that of his neighbor, or stops his ancient lights; or the nuisance may affect incorporeal hereditaments, as when one ploughs up the road in which I have a right of way across another's land. It will be seen that these illustrations of private nuisance approach very nearly to the offence of trespass. Of the first indeed, Blackstone expressly says it is a species of trespass, for *cujus est solum, ejus est usque ad caelum*, he who possesses the land possesses also that which is above it; and the last is the case of infringement

of a right, which, though not corporeal, is yet clearly determined. Yet, however much cases like these may resemble trespass and differ from public nuisance, they cannot be ranked with the former, for they lack some of its technical elements, as, for example, the direct application of force, which is the criterion of trespass; and they may be well enough ranked with the latter, because they have so much in common with it. Nuisance, then, whether private or public, is rather a tortious than a criminal act. It is not committed with force, either actual or implied. The injury of it arises rather from misuse of one's own, than from abuse of or aggression on another's right; and it is therefore indirect or remote, as distinguished from actual invasion of another's property. It would be trespass, that is, a plain infringement of another's right, to enter without his permission, express or implied, upon his land or into his house; but it is less clear that an offence has been committed when one complains that his neighbor has injured him by erecting a building so near him as to darken his windows, or by keeping a swine yard so near as to lessen his comfortable enjoyment of life. The nuisance is by so much less clear than the trespass, as the rights which the complainant sets up in the latter cases are less nicely marked than those tangible ones of corporeal property which are invaded by the trespass. So in respect to public nuisance, the offence consists in an encroachment on common rights of the whole society, which, from their nature, are determined with very various degrees of certainty. If one obstructs the public highway, the case is clear; but it is not quite so evident that a bowling alley is a public nuisance, and it may require a legislative act to show that to keep liquors for sale is an offence of the same character. The public wrong differs, too, in different communities. A knacker, for instance, may legally carry on his offensive trade in an uninhabited tract of country, but he is guilty of a public nuisance if he exercises it in the midst of a town. Indeed, when any one even of one's absolute rights diminishes the general welfare, it becomes misuse of them and nuisance. In respect to public nuisance, it is to be further observed, that as the legislature represents the whole society and is the particular custodian of the public welfare, no act which it authorizes can be declared a public nuisance. This has been so held in respect to railways laid in the streets of cities under legislative charters; and in the case of a railroad, the locomotives on which frightened the horses of passengers along a parallel highway, it was declared to be no nuisance, because the public benefit may be supposed to have been regarded by the legislature as sufficient compensation for the inconvenience. Yet any abuse or excess of the privileges thus granted, intrudes on the domain of public rights and is a nuisance to them. It may be added here, that when public squares or places

have been illegally sold by the authorities, and the public enjoyment has been obstructed by the erection of private buildings, the owners of these may be indicted for the maintenance of common nuisances.—A good criterion of nuisance was suggested by the court in a late English case in the following language: "Is the inconvenience one of mere delicacy and fastidiousness, or does it interfere with the ordinary physical comfort of human existence, not merely according to elegant or dainty modes of living, but according to plain, sober, and simple notions?" Public nuisances, says a late accurate commentator upon the criminal law (Bishop), may be defined as all those acts put forth by man, which tend to create evil consequences to the community at large, and are of sufficient magnitude to require the interposition of the courts. They are, then, injuries to that aggregate of rights which constitutes the well-being of society. All acts therefore which imperil the public safety or health, or disturb the public convenience, are indictable as common nuisances. Such acts are the keeping of gunpowder in mills or magazines in a dangerous manner, near the dwellings of citizens or near a public highway, or carrying on offensive trades in populous places; and it is not necessary that this affect the health; it is sufficient, said Lord Mansfield, if it lessen the enjoyment of life. So it is an indictable offence to expose a person infected with a contagious disease in a public street. With regard to offensive trades, it was formerly held to be the rule that if one had been for a long time carried on in a locality remote from habitations, those who afterward came to dwell in the vicinity had no ground to complain of the nuisance. But a late case in Massachusetts holds what seems to be better doctrine, to wit, that no one can have a right to use his own land so as to render that about him in any degree useless. His enjoyment must have reference to the rights of others, and be subordinate to the general laws which have been devised for the common benefit. So it was held in respect to a bathing place in England. When it was urged in defence that it had been, time beyond memory, the resort of bathers, the court said that, the neighborhood having lately become thickly populated, the ancient enjoyment of the beach must cease; for whatever place may become the dwelling of men, there the laws of decency must be observed. All injuries to the highway, as obstructions of it or narrowing it, which render it less commodious to the public, are nuisances at common law. One has been held to be indictable who, by exhibiting effigies in his window, attracted such crowds to look at them as to hinder free passage along the road. As it disturbs the public order, that is a common nuisance which corrupts the morals of the community. Profane cursing and swearing in public is indictable as a nuisance. So are open lewdness, disorderly inns, and bawdy and gaming houses. In New York

erections of every kind adapted to sports having no useful end, and notoriously fitted up and continued with a view to make profit for the owner, are declared to be nuisances. Such an establishment is a bowling alley, kept for gain or hire, even though gambling in it were expressly prohibited. But keeping a billiard room without allowing any noise to disturb the neighborhood, and without allowing any bets in the game, is not indictable.—The remedies for nuisances vary with the character of the injury. In the law the remedy is always adjusted to the wrong. For a private wrong there is a private remedy by civil suit, and for a public wrong a public remedy by indictment; but never a private action for a public mischief, nor a public prosecution for a private injury. Compensation for a private nuisance is sought therefore by private action; but in the case of a public nuisance, though each member of the society is in fact wronged, yet no one may have a private suit. Thus if A dig a trench across the highway, the act is a public grievance; but no individual can make the offence a cause of action, for no one can ascertain his particular proportion of the damage; and even if he could, it would be highly inexpedient that the offender should be pursued by the separate suits of all the citizens. But if B fall into the trench and sustain particular damage, this will give him cause of separate action, not founded at all upon the nuisance, for that is matter of public concern, but on the private damage which the public wrong has caused him particularly. In other words, A's tortious act, though immediately a public offence, has yet wrought consequentially the same injury to B which a direct personal trespass would have wrought. For what we may call B's public right of free passage along the highway he has no right of individual action, but must join with the whole body politic in a public prosecution.—It is familiarly known that he whose rights are prejudiced by a private nuisance may abate it, that is, may remove it by destroying, if need be, the cause of nuisance; and as a public nuisance injures equally all the members of the society, it has been laid down that any one of these has the right to and may legally abate it. Thus, says a text writer of authority, if any one whose estate is prejudiced by a private nuisance actually erected, may justify the entering into another's ground and pulling down and destroying such nuisance, it cannot but follow *a fortiori* that any one may lawfully destroy a common nuisance. But it is also the law in respect to private nuisance, that one may abate so much and only so much as is a direct injury or nuisance to him individually; and this will appear reasonable when it is remembered that it is just this direct injury which gives and measures the right of private suit. In private nuisance, then, one may abate as he may have his civil action, in both cases for the special injury. Now in respect to public nuisance we have seen that the law permits no individual

citizen to prosecute the public wrong, but limits him to a private action for his private damage. By analogy with the case of private nuisance, it would seem that, in respect to public nuisance, the right of individual action should measure the right of individual abatement; that is to say, that an individual would be privileged to abate a public nuisance, not as such and merely because it existed, but only when, and so far as, it interfered with his individual rights; in short, that he might abate in those cases only in which he might have a separate action. This is the doctrine lately held by the supreme court of Massachusetts in a noted case in which the plaintiff brought an action of tort against defendants for their destruction of certain spirituous liquors. They pleaded in justification that the keeping of such liquors was declared by statute to be a common nuisance, and therefore that any one might abate it. The court said that, though the doctrine has been sometimes stated in terms so broad as to give countenance to the supposition, yet it is not lawful by the common law for every and all persons to abate a public nuisance. This right is generally not intrusted to individuals without process of law, by way of vindicating the public right, but solely for the relief of a party whose right is obstructed by such nuisance.—The remedies at law can at most only abate or afford compensation for existing nuisances, but are ineffectual to restrain or prevent those which are threatened. There is therefore a jurisdiction in equity over nuisance, by process of injunction; but the jurisdiction will be exercised only when the fact of nuisance is clearly made out, and when it is proved that, from the nature of the case, the injury is not susceptible of adequate compensation at law.

NUKAHIVA. See MARQUESAS.

NULLIPORE, the name of a division of the coralline order of marine plants, belonging to the florideous algæ. These are rigid calcareous sea weeds, composed of closely packed elongated cells, in which carbonate of lime is deposited; their name is derived from their having no visible pores on the surface. They usually have the form of a disk, sometimes of tufts, with crustaceous or foliaceous non-articulated fronds, and vary in hardness from cartilaginous to stony. They incrust rocks or other algae on the edges of the sea in all latitudes, but most abundantly within the tropics. They have been alternately placed among animals and plants, but are now regarded as without doubt belonging to the latter; reddish or purple when recent, they soon fade to a milk white. *Melobesia* is the type of the nullipores, according to Harvey and Agardh. (See ALGÆ.) These marine vegetable growths have been instrumental in building up islands, like the Tortugas and the Marquesas, and have furnished the principal materials for some calcareous strata of past geological ages.

NUMA POMPILIUS, the second ante-historical king of Rome. After the death of Romu-

lus there was an interregnum of a year, each of the senators in turn enjoying the royal prerogative. At the end of this time the people became discontented, and demanded the election of a king. But when the senate had given its consent, a dispute arose between the Sabines and Romans, as to which tribe the sovereign should be taken from. At last, it having been agreed that he should be selected by the Romans from among the Sabines, Numa Pompilius, of the town of Oures, was unanimously chosen. His first care was the reformation of the civil institutions. He divided the lands which Romulus had gained by conquest, founded the worship of Terminus, the god of boundaries, and divided the artisans according to their trades into 9 companies. He was considered as the author of the Roman ceremonial law. He regulated the duties of the pontiffs, who had charge of the enforcement of the laws relating to religion, the augurs, the flamens, the vestal virgins, and the Salii, and prescribed the rites of worship. He reigned 89 years, and in all that time, as Livy relates, there were no wars, famines, or plagues. He was buried under the Janiculum hill. At his death the nymph Egeria, who had been his guide and counsellor through life, melted away in tears, and was changed into a fountain. According to popular tradition he had also derived much of his knowledge from the Greek Pythagoras, which critics generally regard as an anachronism, though according to Niebuhr the personality of Pythagoras is no more certain than that of Numa. The sacred books of Numa, prescribing religious rites and ceremonies, were said to have been buried near him, and to have been discovered 500 years afterward (181 B. C.).

NUMANTIA, an ancient city of Spain, and the capital of the Arevaci, supposed to have been in Hispania Tarraconensis, on the present site of Puente de Don Guarray, on the Douro, 3 m. N. of Soria, Old Castile, where ruins exist. It was the most important place in all Celtiberia. After the fall of Carthage, the Numantines resolved not to surrender to the Romans, and defeated in succession the consuls Quintus Pompeius, Popilius, Mancinus, and Lepidus, who were sent against them. Finally, Scipio Africanus the younger besieged them with 60,000 men. The Numantines, who numbered no more than 4,000 able to bear arms, held out bravely for 14 months, when, their provisions being exhausted and their sources of supply cut off, they set fire to their houses and killed their wives, their children, and themselves (133 B. C.). The conqueror took the title Numantinus.

NUMBERS, one of the canonical books of the Old Testament, and the 4th of the 5 books of Moses. It is called in the Hebrew canon *Be-midbar*, "in the desert," from a leading word in the 1st verse of the opening chapter, and describes the numbering of the children of Israel, the continuation of the laws given to Moses in the wilderness of Sinai, the march

through the wilderness, the rejection of a whole generation, and the entrance into the land of Canaan. Historically it comprehends a period of 88 years, opening with the second month of the second year after the deliverance from the land of Egypt; but it is chiefly confined to the first and last of these years. The authenticity of the book of Numbers has frequently been impugned, and some critics who admit its genuineness are disposed to give it a mythical character; but the majority of biblical students receive it literally, alleging its minute and straightforward narratives and other internal marks as strong objections to such a hypothesis.

NUMIDIA, an ancient country of northern Africa, corresponding to the modern Algeria, and bounded, in the time of its independence, N. by the Mediterranean, E. by the river Tusca (now Wad-il-Barbar), which separated it from the territory of Carthage, and W. by the Malva or Mulucha, which separated it from Mauritania. On the south it extended indefinitely toward the Great Atlas range and the land of the Gætuli. It was divided into an eastern and western part by the river Ampsaga, was intersected by the Lesser Atlas, and was rich in good pastures, owing to the numerous streams which flowed from that range into the sea. In early times the country was occupied by tribes of Asiatic origin, from whose nomadic mode of life it was supposed by some to have received its name (Gr. *Nouadia*, or *ἡ Νομαδική*). Among the principal towns of Numidia were: Hippo Regius (now Bona), the capital of the Massylians, and see of St. Augustine; Cirta (Constantine), the residence of Masinissa; Zama, famous for the defeat of Hannibal; Cæsarea, which at a later period gave name to Mauritania Cæsariensis; and Siga, the capital of Syphax. The Numidians were renowned as skilful horsemen. When the Romans, during the 2d Punic war, first entered into relations with the Numidians, the Massylians were the principal tribe E. of the Ampsaga, and the Massesylians W. of it. Masinissa, the son of Gala, a king of the former, having allied himself with the Romans, after various struggles became master also of the possessions of Syphax, the rival king of the Massesylians, and in a long reign made the united kingdom powerful and prosperous. Of his 8 sons, who according to his will divided the country after his death (148 B. C.), Mastanabal and Gulussa died soon after, and the kingdom was reunited by Micipsa, who died in 118, bequeathing his possessions to his sons Adherbal and Hiempsal, and to his nephew Jugurtha. The former soon fell victims to the treachery of the latter, who himself ended his life in a dungeon of Rome, as captive of the republic (106). Numidia was bestowed by the conquerors on Hiempsal II., a prince of royal blood, whose son and successor Juba, having fought with the adherents of Pompey against Cæsar, shared in their defeat at Thapsus (46), and died by his own hand.

Numidia was made a Roman province, and its western part as far as the river Saldæ annexed to Mauritania. Augustus restored Juba II. to his father's kingdom, but subsequently made him king of Mauritania and the land between the Malva and Saldæ, converting the territory between the latter river and the Tusca into a Roman province. Another part between the Saldæ and the Ampsaga being annexed to Mauritania under Claudius, the eastern division alone, also called New Numidia or Numidia Proper, formed a province of the later empire.

NUMISMATICS, the science of coins and medals. Strictly, the study of numismatics has no relation to the value of coin as a circulating medium, but only to the history of coins and medals in all ages and countries, the formation of collections of such memorials as are furnished by the gold, silver, and copper issues of coins and medals, and the study of history as illustrated by the images and superscriptions which they bear. In the articles COINS and MONEY some information has already been given on this subject, which it may be necessary to repeat in part under the present head. The study has its chief value in illustrating history. Coins of all periods have borne on their faces either mythological or historical figures; and in the acquaintance which their study gives us with the portraits of distinguished persons, in its preservation of ancient works of art, in the representation of ancient manners and customs, and in the illustrations, it furnishes of ancient literature, may be found ample justification of the attention it has received.

—A coin is a piece of metal bearing an impressed device, and designed for circulation as money. A medal is a large piece of metal struck with one or more dies, intended to commemorate some event, and not designed for circulation. A medallion is now generally understood to be synonymous with a medal. A medallet is a small medal, and usually but not necessarily of inferior workmanship. A token is a small medal, usually but not always of the same size with the current coin of the country in which it is struck, and issued for purposes of private individuals. The obverse of a coin or other piece is that side which bears the portrait or principal design indicating the country, nation, or object for which it was struck. The other side is the reverse. The head or portrait on a piece is said to face to the right or left with reference to the beholder's right or left hand. When the design on a specimen varies in any decided characteristic from one already known, while the general object and purpose is manifestly the same, this is said to constitute a new type. When the variation is very slight, as in the size of the lettering or the distance between letters, it is classed as a variety. Proofs are coins or medals struck from the original die as it leaves the hands of the die cutter, and are thus distinguished from specimens struck with dies which have been reproduced by pressure from the original dies. Pattern or

mint pieces are coins struck in any mint and proposed for adoption in the coinage of a country, but not adopted in the year of their first manufacture. The abbreviations AU. or AV., AR., and Æ. signify respectively *aurum*, gold, *argentum*, silver, and *æs*, brass or copper. Electrum, a native amalgam of silver and gold, was also used in ancient times for coins. The term billon denotes a debased silver used in some coinage. Brass was used for coin in ancient times, and is frequently used in modern times for tokens and medallets. Potin is a softer alloy than billon. The field on a coin or medal is the open space not occupied by a device or inscription. The exergue is variously understood as the open space outside the figure and inscriptions, or as the portion of that space below the main device, and distinctly separated from it. Strictly, the exergue only belongs to the reverse of a coin, but in America this distinction is not preserved. The legend is usually understood to be any inscription other than the name of the monarch or personage represented on the coin or medal. The inscription includes any legend, names, titles, &c. A mint mark on a coin is the private mark placed on it by the mint to indicate genuineness, or the place of coinage, or for some other purpose. The size of coins or medals is measured among numismatists by arbitrary scales. In Europe Mionnet's scale is generally used. In America a scale of sixteenths of an inch is much in use, and a medal of size 24 is 24 sixteenths of an inch in diameter across its face.—The study of coins and medals and the collection of cabinets of specimens have been pursued for a long period. It is probable that the Romans gave much attention to the science of numismatics, and it seems also likely that some fine specimens now in modern cabinets have occupied similar positions in collections of Roman virtuosi. But the science was never pursued with great ardor until comparatively modern times. Petrarch was traditionally the first of modern collectors. Since his time collections have increased vastly, until now there are very many fine collections in every civilized country. The British museum collection contains over 120,000 varieties; the Paris collection is somewhat larger, and each is increased by the addition of 3,000 to 4,000 pieces annually. No large collections have been made in America, but numerous small and valuable private cabinets are known.—Up to the 9th century B. C. the metals had been used for the purposes of exchange by weight. It is an interesting fact that the earliest recorded use of money for a purchase is that of Abraham, buying a grave for his family. In this instance he is said to have used shekels; and this Hebrew word receives some explanation from a similar transaction recorded of Jacob, where the price paid was "pieces of silver." The word here translated "pieces of silver" may also be translated "a lamb;" and the question has arisen whether the payment was not made in lambs or in live stock. An Egyptian

picture of very early date has been discovered in a tomb, which exhibits a scribe weighing out rings of gold and silver, and using small weights shaped like lambs and half lambs. This would seem to indicate that the first standards of money may have been the value of animals of this kind; and the idea receives further encouragement from the fact that the Romans in the 6th century B. C. commenced their first coinage of brass with the issue of large pieces bearing on their faces the images of animals of domestic use. Hence came the word *pecunia*, money, from *pecus*, the flock; and our pecuniary, derived from this, may thus carry us back to the very earliest periods of dealing between man and man in barter and sale. Rings of metal, usually gold or silver, had been used as money for a long time prior to the origin of coinage. The Egyptian monuments illustrate these rings, and in Britain great quantities have been found, some of large size, seemingly worn over the shoulder or around the body as ornaments, but probably serving the purposes of money, as indicated by the fact that their weights are all exact multiples of one and the same standard or unit. The Greeks are said to have used bars or spikes of metal, and from this came the Greek nomenclature, an oboliscus (*ὀβολισκος*) being an obelisk or spike, and 6 oboli making a drachma (*δραχμη*), a handful, the latter being to the present day the name of a coin in Greece, and having passed into various languages as a weight and measure.—The oldest coins extant are probably those of Ionia, having been produced at Miletus, a city on the coast S. of Ephesus, in the 9th century B. C. This coinage was a stater of gold (or electrum), having a rude punch mark indented on one side and a lion's head raised on the other. The coin was evidently driven into the die with the punch. This continued to be the general style of coinage for some time in the Greek countries. The first improvement in the art consisted in giving to the end of the punch some rude design, which was followed up by making the punch correspond to the die, so as to produce a coin with a design convex on one side and concave on the other. This again gave place to the ordinary style of coins ever since in use. The honor of originating coinage has been by some assigned to Lydia, instead of Ionia; by others to Ægina, where silver was first coined; and by others still it has been supposed that the Persian Dario was of the earliest date. The earliest gold coinage was the stater or standard (a coin not varying much from the size and value of an English sovereign), and its fractions. The silver coinage was the drachma and its multiples, the most common of the latter being the didrachma or 2 drachmas, and the tetradrachma or 4 drachmas. At a period not long after the origin of the art the various sizes and values of coins were much increased, and we have gold distaters, commonly called gold tetradrachmas, hemistaters, commonly called gold drachmas,

and silver octodrachmas and pentadrachmas, and various other sizes of both metals.—In classifying the coins of the ancient world, the grand divisions may be stated as the Greek, the oriental, and the Roman, each of these comprising under its general name the coins of cities, colonies, and sometimes of barbarian nations who adopted types belonging to one of the great classes. There are coins of Spain, Gaul, and Britain, which may be placed in each of these classes. The great popularity of the gold coins of Philip of Macedon led to the adoption of rude imitations in many of the barbarous nations, those mentioned above among the number. The first coinage of silver was that of Ægina, at a date not long after the first Ionian coinage of gold. The die was still of the earliest known form, and the extant pieces bear the rude punch mark on the reverse, and an almost equally rude design of a tortoise on the obverse. The usual inscriptions and devices on the earliest coinage of the Greeks were of a sacred character. The first types were generally of local genii, river gods, animals, nymphs, and the like. These were succeeded by heads of the gods. The inscription was usually the name of the city, country, or monarch issuing the coin, and in the genitive case; thus, ΑΛΕΞΑΝΔΡΟΥ, of Alexander. By some the word money is understood; by others (especially Mr. Burgon, an eminent English numismatist) the use of the genitive is supposed to refer to the type or figure represented on the coin, as Minerva of Athens, Arethusa of Syracuse, &c. The latter supposition is however difficult when applied to such coins as the Ptolemaic, which have only the head of Jupiter and an eagle, and the inscription: "Of Ptolemy the king." Portraits do not appear on coins till the time of Archelaus I. of Macedon. Even his head is doubtful, and some contend that no human head appears on a coin until after the death of Alexander the Great, when his head was admitted as in some sort that of a divinity, and thus for the first time broke in on the Greek dislike to the profanity of placing a human image where the gods had a sort of right of possession. The reverse types remained sacred for a long period, and it seems probable that all the representations found on ancient coins of statues, groups, monuments, &c., are copies of actual existing objects of public devotion or respect and admiration, instead of being the mere fancy of the engraver.—The Greeks, having originated the art of coining, have also the credit of bringing it to its greatest perfection; and although modern art has invented new processes for striking coins, and as a result of machinery has created a greater uniformity in coins as to appearance and shape, yet the most elaborate modern coins cannot be said to surpass the coins of the Macedonian empire in purity of metal, or boldness and beauty of design. In the period of Alexander the Great the gold coinage of the empire was immense, and the head of Philip on those

of his father and the name *Φίλιππου* (the son of Philip) on his own gave to these coins the name of Philips, which they retained through many reigns, like the louis d'or of France in modern times. The gold coins of Alexander are even at the present day abundant, and there are doubtless more specimens of them now in existence and in the hands of collectors or travellers who have picked them up than could be found of any American gold piece of the last century.—The spread of the art was very rapid. There was almost no colony of Greece, and certainly no independent nation, which did not have its coinage. The labor of the numismatist becomes herculean when he would trace the various coinages. There are extant more than 1,000 series known under the name of Greek autonomous coins, or coins of self-governing cities, many of them of large extent in point of numbers. We have also the splendid series of the Parthian kings, the more splendid Macedonian, and the Armenian, Bactrian, Syrian, Thracian, Bithynian, Cappadocian, Carian, the Ptolemaic series of Egypt, and almost countless others, all including large varieties extending through many years, sometimes through centuries, and all distinct from the Roman empire and its dependencies.—The Chinese coinage was of very early date. Some specimens are said to be of as early a period as the 21st year of King-wang of the Tcheow dynasty (523 B. C.); but Baron de Chaudoir, the best authority, thinks there is no certainty of any prior to Chi-hoang-ti, of the Tsin dynasty (247 B. C.). The form was similar to that now known, circular with a square hole in the centre, and the metal copper. The Hindoo or Indian coinage is of early origin, but the date is obscure. There are square copper coins with a Pali legend, which are conjectured to be of the 8d century B. C., but the earliest certain dates are about 100 B. C. It would be obviously impossible to trace the spread of the art through the world, or even to give an outline of the several great classes under which the ancient coinages have been arranged. The Hebrew nation seem to have been singular in this as in many other customs. They had no coin of their own until the time of the Maccabees, when Simon, by virtue of the decree of Antiochus (1 Macc. xv. 6), issued a coin known as the shekel, and also a half shekel, with such inscriptions as "Shekel Israel," "Jerusalem the Holy," and "Simon prince of Israel." This coinage does not appear to have been continued after the time of the Maccabees. These, with some small brass coins of the Herods, Archelaus, and Agrippa, and a doubtful coin attributed to Bar-Okeba, the leader in the last rising against the Romans, are the only coins of Judæa which are extant.—The Romans began the coinage of brass in the reign of Servius Tullius, 578 B. C. The name of the metal, *æs*, gave the name to the standard or unit coin, which was called the *as*. The *as* was in fact at first a pound of copper, and hence the coinage is known as the

Roman libral coinage. The fractional coin was the *uncia* or ounce, the 12th part of the *as*. In the course of time the weight of the standard was largely reduced. At the time of the 1st Punic war, about 261 B. C., it was $\frac{1}{2}$ of its former weight; about 217 it was reduced to one ounce, and in 191 to a half ounce. Silver was first coined in Rome about 270 B. C., and gold about 207. The Roman gold coin which was the standard was the *aureus* or *aureus nummus*, answering to the Greek stater. The silver coin which may be considered the unit of the silver currency was the *denarius*, probably originally intended to be of a weight corresponding to the drachma of Greece. This *denarius* continued to be used throughout the history of the Roman empire, and was the predecessor of the English silver penny, known by the letter *d*, in the nomenclature *£. s. d.* These *denarii* are found in immense numbers and variety. For a long period before the empire, and even after its commencement, family names and devices were used on the coinage of various portions of the Roman possessions. These coins are now classed as the Roman family coinage. The imperial coinage succeeded, and numismatists are accustomed to class the gold, silver, and copper or brass coinage distinctly, dividing the latter into 1st, 2d, and 3d classes, according to size. Some of the emperors evinced a respect for coins as monuments by restoring the coins of their predecessors, that is, reissuing them with an inscription indicating that they were *restituti*.—In the eastern empire the coinage became very rude; and in mediæval times the art of coinage had so far receded instead of advancing, that the coins of Europe and the East during that period are in no respect better than the rudest form of Ionian coinage. The Saracens indeed were quite equal to the Christians in the art, and the best coins of Europe during this time were imitations of the splendid Macedonian coinage, so miserably poor as to be ludicrous. The various provinces of Europe issued a rude form of coinage, from which gradually sprang the present magnificence of the art in all parts of the civilized world. But during the middle ages, especially from the 10th to the 12th century, the coinage of all Europe was a close imitation of the Byzantine currency, itself exceedingly rude and imperfect; and it is in England that we first find the art beginning to emerge from its state of depression. England probably had no coinage prior to the Roman invasion. There are extant numerous small silver pieces bearing the names of early British princes contemporary with Julius Cæsar; but whether they are of that period, or, as has been suggested, are tokens struck at a later time, remains a subject of discussion. The Saxon *sceatta* were the first English coins of which we have any certain knowledge. They were of silver, and worth about the same as the *denarius* or silver penny. They in fact gave place to the silver pennies of the Saxon kings,

of which many are extant, the earliest known being one of Ethelbert II., king of Kent in the 8th century. William I. introduced the Norman shilling as a name of money, but not as a coin. The Saxon *scilling* or shilling was 5 pennies, changed afterward to 4 pence. The shilling was first struck as a coin in the reign of Henry VII. A few gold pennies were struck in the reign of Henry III., but the English gold coinage was first fairly commenced under Edward III. by the issue of florins and half and quarter florins, names derived from an early gold coin of Florence; but these were recalled, and the gold coinage of nobles commenced. From this period the English coinage has been progressing to its present perfection. The only feature in it which we pause to notice is the occasional issue of sleeve pieces or pieces of necessity, which are known to numismatists, and some of them highly prized. They were pieces of plate or even gun metal, cut up and stamped at times when royalty was forced to such a use of bullion in the absence of a mint, or in its own absence from mint conveniences. In the latter half of the 18th century, when copper money became scarce in England, a large issue of tokens was made by private tradesmen. These were usually of the value of a penny or a half-penny, and corresponded in size to those British coins. Among them were numerous devices referring to America and the late revolution, and on several the head of Washington appeared. (For the history of coinage in America, see *COINS*.)—The issue of medals seems to have been a very early custom. Many of the largest pieces of ancient coin so called are more correctly to be considered as medals, struck for prizes in the games, or in commemoration of great events. The Roman series of medals or medallions is very extensive in gold, silver, and brass or copper. They are usually larger than the largest known coin in the same metal, and, though multiples of the same unit, were not coins. The gold medals begin with Constantine, and continue to the fall of the empire; the silver begin under Gallienus, and continue as long; the copper from Augustus to Alexander Severus. In more modern times the art of medal making has been brought to great perfection, and most of the nations of Europe have adopted the plan of preserving their history by these durable monuments. The numismatist collects medals with quite as much interest as coins. In general, however, collectors find it sufficient to devote their attention to the medals of their own countries. The French series is perhaps deserving of special mention as the most perfect and complete in the world. It commences under Louis XI. and continues to the present date, illustrating every important event in the history of France. The English series is not to be compared with the French. It commences under Henry VIII., and continues with many long intervals to the present time; but as works of art the medals of England have not high rank. England has

adopted a plan of striking medals commemorative of battles, which are presented to deserving soldiers; and to avoid the inconvenience of carrying several large medals on the breast, the plan is now adopted of adding a new clasp to the ribbon, inscribed with the name of the battle, in place of giving a new medal. The British battle medals form an admirable series. The Italian and German medals of modern date are very fine; the mediæval are interesting and bold in design, but rude in execution. The papal series, commencing with Paul V., may be mentioned as worthy a collector's attention. In America there were few medals struck until a comparatively late period. The revolutionary medals, presented by congress to officers of the army and navy, are the first of the series. These were all or nearly all struck in France. The issue of medals from the mint has been chiefly confined to the occasional striking of one to be presented to Indian chiefs, or presentation medals ordered by congress. Agricultural societies and others issue medals as prizes, and of these there is a large and increasing variety. Medals are struck in gold, silver, copper, and white metal. Bronze medals are copper medals bronzed. White metal is a composition, nearly as soft as lead, the alloys varying according to the taste of the manufacturer. Political medallions and tokens are often struck in this composition.—Coins and medals would be more valuable aids to illustrations of the study of history were it not for the existence of counterfeits, both of ancient and modern manufacture. Some able artists have devoted their talents to the production of false specimens of rare ancient coins. Benvenuto Cellini did not disdain this employment. Two artists at Padua produced so many that the name *Paduan* was applied as a common epithet to all such coins. Devrieux and Weber at Florence, Carteron in Holland, Congornier at Lyons, La Roche in another part of France, and Caprara at Smyrna, were among the chief counterfeiters; and their work has become a matter of numismatic interest, so that their coins command high prices as curiosities. They either altered known coins, or struck new ones, or split the old specimens and rejoined the halves which did not belong to each other. The rare coins of Otho, Pescennius, Pertinax, and other Roman emperors, are most commonly imitated. American colonial coins and rare pieces are manufactured very skilfully in New York, and nothing is more common than to find rare dates on coins carefully altered from common years. The electrotype process, of course, is a great aid in this species of fraud. The deception has been carried so far in the East as to supply Arabs with coins, who pretend to dig them from the sand before the eyes of a deluded traveller.—The prices of coins and medals have varied as the taste of collectors has been directed more toward one or another series or class. Very rare ancient gold and silver pieces have been sold by auction in

England for prices as high as \$1,500, when the intrinsic value of the metal was less than \$1. Some American colonial coins bring high prices at sales. The Washington half dollar of 1792 has been sold by auction for \$57, and the same piece in copper for \$64. The Granby copper has been sold at private sale for \$50. Cents of 1793 and 1799 have been sold for \$10 and \$15, and half dollars of 1796 and 1797 for \$25. Collectors generally prize fine and uncirculated pieces, even of common dates, at higher rates than poor pieces of rare dates.—The number of works on numismatics is believed to be many thousands. On ancient coins, see *Doctrina Nummorum Veterum*, by Joseph Eckhel (9 vols. 4to., Vienna, 1792-'8), and *Description des médailles antiques, &c.*, by T. E. Mionnet (6 vols. 8vo. and 1 vol. plates, Paris, 1808-'13; with supplement, 9 vols. 8vo., 1819-'87); on British coins, "Annals of the Coinage of Great Britain and its Dependencies," by the Rev. R. Ruding (3 vols. 4to., London, 1840); "A View of the Coinage of Scotland," by John Lindsay (4to., Cork, 1845), and "A View of the Coinage of Ireland," by the same (4to., Cork, 1839); on American coins, "The American Numismatic Manual," by M. W. Dickeson (4to., Philadelphia, 1859).

NUNCIO (Lat. *nuntius*, messenger), a prelate representing the Roman pontiff near a foreign government. Strictly speaking, he represents the pope only as temporal sovereign, but he is often commissioned to treat of spiritual affairs, and to report on the condition of churches and the character of church dignitaries, especially of candidates for the mitre. A nuncio may be resident or extraordinary; and if appointed simply to fill a vacancy, he is styled an internuncio. The nuncio in France is forbidden by law to exercise ecclesiastical jurisdiction, being recognized only as the papal ambassador. The only nuncio who has ever visited the United States was Archbishop Bedini, in 1853.

NUÑEZ, ALVAR (CABEÇA DE VACA), the earliest and most remarkable explorer of North America, and one of the associates of Pamfilo de Narvaez, the first governor of Florida. Having obtained from the king of Spain an appointment as governor of Florida, Narvaez fitted out an expedition for the purpose of exploring and taking possession of this country. He was "authorized and commanded to conquer and govern the territories that extend from the river Palmas to the cape of Florida, which are on the main land." His chief officer was Nuñez, better known as Cabeça de Vaca, who is styled "treasurer and high sheriff." The flotilla, which consisted of 5 ships with 600 men, sailed from the harbor of San Lucar de Barrameda, July 17, 1527. Arriving at St. Domingo, they remained there 45 days to procure certain necessities, but chiefly horses. After stopping at various places for supplies, and meeting with many delays, they arrived at Xaqui, where they wintered. Sailing again

with 400 men and 80 horses, they reached the coast of Florida, where they landed, April 12, 1528. Narvaez now directed the flotilla to follow the coast westward to a certain haven, and there await his coming; while he, accompanied by Nuñez, entered the interior with 300 men in search of a place called Apalachen, where, he was told by the natives, there was a great quantity of gold. They reached this place on June 20, and remained at it 25 days. Disappointed in the object of their search, they proceeded to a place called Aute, and thence to a river which Narvaez named Madelena, following which they reached the sea. The country traversed possessed few attractions, and most of the Indians whom they met showed great hostility. The Spaniards also suffered greatly by sickness; they were disappointed in their expectations of finding gold, and were sick and disheartened when they reached the coast. Narvaez did not find his fleet as he expected, nor did he know whether or not he was at the appointed haven. It seems that his officer in charge of the ships did not make any effort to reach the place of rendezvous, but returned to Havana, leaving the governor and his companions to their fate. To get away from this region they must construct boats for 800 men. Without tools, forge, oakum, pitch, or ropes, and with a limited supply of provisions, this was a task of great difficulty. In the emergency, one of the men said that "with certain pipes of wood and skins of wild beasts, he would make bellows that should be made to blow." This revived their hopes. They then took their spurs, stirrups, cross bows, and other articles of iron, and converted them into nails, saws, hatchets, and other necessary tools. While the work was going on, they supplied themselves with maize from Aute, and every third day killed a horse. For oakum they used the bark of the palmetto, which they caulked with a species of gum from a pine tree. For cordage they used the palmetto, as well as the hair from the manes and tails of their horses; and for sails they used their shirts. For water vessels they flayed the legs of their horses whole, and sewed the skins together. On Sept. 20 they had completed 5 boats, in which the whole party, now reduced to 242 men, embarked. But when all their effects were shipped, the boats were scarcely above water, and so crowded were the men that it was with the greatest difficulty they could manage them. A few days afterward they obtained an Indian canoe. They followed the Florida coast for 47 days, when they landed on a small island where they were detained by a violent storm. Here 5 of the men died from the effects of drinking salt water. After this they followed the Indians and obtained fresh water; but the same night the natives rose on them and drove them off, wounding many, among them the governor. After continued suffering from hunger and thirst, from attacks by the Indians, from vio-

lent tempests and severe cold, they at length reached the mouth of a large river, and landed on an island. They attempted to go up this river, but the current was so strong that they were driven back. From the description given by Núñez of its strong current, and the distance it was found to be fresh after it entered the sea, it is believed to have been the Mississippi. If so, Narvaez was the first to discover the mouth of this river on one of the latter days of October, 1528. They continued their voyage a few days further to the westward, buffeting the winds and waves, when they were overtaken by a violent storm, which scattered their boats and drove them out to sea. As nothing was ever heard of them afterward, except those in a single boat, they doubtless perished. The boat containing Núñez was wrecked on a small island, from which the survivors reached the mainland. They now made their way westward amid unheeded hardships, in which they were driven to such straits that they lived upon one another. Núñez states that from May he had eaten nothing but maize, save in a few instances when fish were obtained near the coast. In tracing his wanderings, we follow him far to the north and west, and across the broad plains and deserts where he finds the buffalo, until he reaches a mountainous country which is believed to have been New Mexico. The fact of his meeting with the buffalo, which has never been found in western Texas south of the great plateau or desert plain, which does not furnish sustenance for them, is evidence that he traversed the country far to the north. His various courses, and the large streams crossed and followed, all go to support this theory. In some places the wanderers found the natives suffering from an epidemic. They all now became doctors, and were remarkably successful in the cure of diseases, gaining thereby a great influence over the natives, who imagined them to be from the sun. "So great," says Núñez, "was their confidence in us, that they thought they could not be healed but by our hands; and they believed that as long as we remained, not one of them would die." The Spaniards took advantage of their influence, and endeavored to instill into the minds of the natives the doctrines of Christianity. This instruction, the enthusiastic historian of the Jesuits believes, paved the way for the missionaries that followed a few years after, as it obtained for them a kind reception. Among the numerous Indian tribes visited by Núñez, those of the present day cannot be recognized; but he says they "travelled through so many sorts of people, of such divers languages, that the memory fails to recall them." Their mode of life does not materially differ from the accounts given by late travellers. Núñez remained 8 months among the Indians of New Mexico, after which he pursued his journey westward and southward, crossing mountains, broad deserts, and rivers,

until 1536, when, with 3 survivors, he reached the Spanish settlements in Culiacan, on the shores of the Pacific. He was therefore 8 years in crossing the continent from the shores of Florida, after a series of adventures the most extraordinary that ever befell any explorer of the American continent. Of his companions, 2 were Spaniards and the other was a negro from the coast of Barbary, named Estevan. Thus did Núñez plant the cross upon the Rocky mountains, and make known the doctrines of Christianity, nearly a century before the arrival of the English on the shores of New England. The accounts given by him on his arrival in Mexico awakened a desire to explore and subjugate the countries he had visited; and soon after Marco de Niza, a Franciscan monk, set out on an expedition for the purpose, with Estevan, the negro, for his guide. The expedition proved a failure, and Estevan lost his life. Other attempts to explore the distant countries referred to followed, the most remarkable of which was that which set out under Coronado in 1540. An abridgment of Cabeça de Vaca's narrative may be found in Hakluyt's "Voyages," and a French version in the collection of voyages published in Paris by Ternaux-Compans; but the fullest and best is a translation by Buckingham Smith, secretary of the U. S. legation in Spain, with annotations (privately printed, fol., Washington, 1851).

NÚÑEZ, FERNAN, a Spanish scholar and soldier, born in Valladolid about 1470, died in Salamanca in 1553. As a member of the house of Guzman he was knight commander of the order of Santiago; and being also the greatest Greek scholar of his country, he was commonly called the "Greek commander." After his return from Italy, whither he went to perfect himself in the Latin and Greek languages, Cardinal Ximenes appointed him one of the Cretan professors of Greek in the university of Alcalá, and also intrusted to him and to Lope de Astuñiga the Latin version of the Septuagint for the Complutensian polyglot. In 1521 he fought on the side of the commons in the "war of the *comunidades*." Being forced to leave Alcalá, he went to Salamanca, and in the university there taught Latin, Greek, rhetoric, and the "Natural History" of Pliny, until his death. He restored the text of Seneca, and published a commentary upon his writings (Salamanca, 1548); also *Observaciones in Pomponium Melam*, *Observaciones in Historiam Naturalem C. Plinii* (1544), and *Glosa sobre las obras de Juan de Mena*. At the age of 80 he was engaged in making a collection of Spanish proverbs, with explanations, and parallel sayings from other languages, which was completed and published by a friend after his death, with the title *Refranes y proverbios glosados* (4to., Madrid, 1555).

NÚÑEZ, PEDRO, a Portuguese mathematician, born in 1492, died in 1577. He was royal cosmographer and professor of mathematics in Coimbra, and wrote on topics connected with

geometry, navigation, the projection of charts, and the improvement of astronomical instruments. He devoted himself especially to the advancement of the art of navigation, and he is considered as the discoverer of the loxodromic curve or spiral. He proposed in 1542 a new graduation of the circles of astronomical instruments, which bears his name.

NUÑEZ, Rio, a river of Senegambia, which falls into the Atlantic in lat. 10° 40' N., after a W. S. W. course of 150 m. The country on its banks is thickly wooded and very unhealthy. About 20 vessels of from 200 to 300 tons each visit this river yearly for the purpose of trade. The imports are chiefly British manufactures and salt; the exports, principally to France, are gold, ivory, hides, wax, and ground nuts.

NUREMBERG (Germ. *Nürnberg*), a city of Bavaria, in the province of Franconia, situated on the river Pegnitz and on the Ludwig's canal, 144 m. by railway N. by W. from Munich, and 106 m. N. from Augsburg; pop. in 1858, 59,177, including 5,000 Roman Catholics and a number of Jews, the remainder being Protestants. The city is surrounded by an ancient wall with 8 gates and about 70 round and square towers, and a moat. The Pegnitz forms 8 islands within the wall, connected with each other and with the city by numerous bridges, the circuit within the wall being nearly 3½ m. The river divides the city into two irregular parts, the southern and larger being called the Lorenzer side and the northern the Sebaldus side. The impression of quaintness and antiquity which the general aspect of the city produces is heightened by the old Gothic style of architecture, and the old-fashioned internal arrangement of many of the houses, their narrow fronts in many instances adorned with paintings. Among the most notable Protestant churches are those of St. Sebaldus, St. James, and St. Egidius, all more or less distinguished for their works of art. The finest and largest of them all is that of St. Lawrence, a Gothic building of the 18th century. The church of the Holy Ghost, which was restored in 1850, contained the jewels of the imperial German crown from 1424 until 1806, when they were removed to Vienna. The Roman Catholic church, or *Frauenkirche*, is remarkable for its richly ornamented Gothic portal. The town hall of Nuremberg is one of the most remarkable buildings of the kind in Europe, on account of its large size, as well as of its collection of paintings by Albert Dürer and other masters. Beneath the building are secret and subterraneous passages; also the *Lochgefängnisse* (dungeons scarcely 6 feet square), and the *Folterkammer* or torture chamber, in which during the 15th and 16th centuries prisoners were put to the rack. The old fortress (*Reichsfeste*), situated on a steep eminence, contains a famous gallery of pictures in 10 rooms and many paintings on glass. The cemetery of St. John contains the tombs of Dürer and Hans Sachs. A statue of the former was erected in

1840 on the Albrecht Dürer's Platz, near the house where he resided. Nuremberg has many fine private buildings and several elegant public fountains. The public library contains upward of 50,000 volumes. Among the educational institutions are an excellent gymnasium, polytechnic, agricultural, mercantile, and normal schools, and a school of design. Since 1857 Nuremberg has become the seat of a new national institution (*Germanisches Museum*) founded in 1853 by Baron Aufsess for the promotion of researches in ancient German history and archaeology. A periodical for *Deutsche Cultur-Geschichte* was established there in 1856 by Müller and Franke, and the *Nürnberger Correspondent* is one of the most widely circulated newspapers of Germany.—Nuremberg was once one of the most prosperous of the free imperial cities, with a population of 100,000 and an extensive trade with the East and other remote parts of the world. It was not less celebrated in the history of art and literature. In the 16th century it was the headquarters of the master singers, and derived great reputation from the genius of Hans Sachs, as well as from that of Dürer, Behaim, and other eminent men. The reminiscences and traces of its former glories continue to make Nuremberg one of the most interesting cities of Germany. It suffered much from the 30 years' war and lost its former commercial greatness, but has improved within the present century, particularly through the influence of railways and the Ludwig's canal, and is now again famous for its industrial activity, particularly in gingerbread, papier maché, toys, &c.

NUT, in botany, a hard-shelled, one-seeded fruit, such as the acorn, chestnut, filbert, beech nut, &c. A variety of useful fruits are known as nuts in horticulture. The European walnut, also called the Madeira nut (*juglans regia*), is much esteemed; when in a tender and unripe condition it is employed for making pickles, and when ripe is used in large quantities as a table dessert. There are many kinds of the Madeira nut known, which are reputed to be of superior quality. The hazel and the filberts are extensively cultivated for their nuts. (See FILBERT.) The chestnut tree (*castanea vesca*) of Europe produces excellent nuts, especially the large-fruited kind, or Spanish chestnut. A dozen or more distinct sorts of chestnuts are known among the French cultivators. The common chestnut of the United States is the product of the *C. vesca*, variety *Americana*, and is smaller and sweeter. The chinquapin bears a small sweet-flavored nut of half the size of the common kind; it is the fruit of a dwarf species growing only 6 to 10 feet high, and found in the middle and southern United States. The several species of *carya* bear nuts, of which the shell-bark hickory (*C. alba*, Mx.) has a very sweet kernel, which renders it the best native nut; that of the mocker-nut hickory (*C. tomentosa*, Mx.) is also sweet, but the thickness of the shell nearly precludes its use. The fruit

of the black walnut (*Juglans nigra*, Linn.) has a round deeply furrowed nut, containing a rich kernel of very agreeable taste; while the butternut (*J. cinerea*, Linn.) has a sweet and pleasant kernel, in a nut which is rounded at base and acute at the end, the sides deeply furrowed, and the edges sharply keeled. The fruit of the beech tree (*Fagus sylvatica*, Mx.) contains two prismatic triangular nuts, having rich oily kernels; they are called beech mast, and from them is manufactured an oil, which in France is used both for cooking and for burning in lamps; in some parts of that country they are also roasted and employed in place of coffee. The beech mast of our woods is eaten by many kinds of wild animals, and in some districts large numbers of swine are fattened upon it. The acorn of the oak is composed of the cupule and the nut; that of the white oak (*Quercus alba*, Linn.) has a sweet kernel, and is eaten either raw or roasted; and the acorns of *Q. graminifolia* (Linn.) are sweet and eatable, and are used for food in Spain under the name of *belotes*. The seeds of the stone pine (*Pinus pinea*, Linn.) are used as nuts under the name of *pignons*, and contain sweet, oily kernels; the tree that produces them grows spontaneously in the south of Europe.—Some tropical trees produce excellent nuts. Those of the *Bertholletia excelsa* are commonly known as Para or Brazil nuts; the kernels when fresh are delicious and nutritive. The fruit of the *Anacardium* is called the cashew nut; it is of the size and shape of a hare's kidney. The kernel abounds with a milky juice, which when fresh has a delicious flavor; but great care is to be observed in removing the shell, between the two layers of which is a quantity of acrid, inflammable oil, which should be destroyed by burning or roasting the nut in the fire, avoiding the smoke in the process. The pistachio nut is the fruit of the *Pistacia vera*, a small tree, native of Asia Minor; the nut is a sort of drupe of the size of an olive, of a reddish color, with a very thin rind, a brittle, 2-valved shell, and an almond-like, oily seed; it is used at dessert and in confectionery. The areca nut is the produce of the *Areca catechu* of Linnaeus, found all over the East Indies; the nuts are astringent, intoxicating, and narcotic, and are used as a masticatory with lime and the leaves of the betel pepper. The cocca-nut is the one-celled seed of the drupe of the *Cocos nucifera* (Linn.), containing a delicious kernel used for food; the tree grows only near the sea coast, especially upon tropical islands. The physic nuts of South America are the seeds of *Curcas purgans* (Adanson); they are cathartic and poisonous. The seeds of the *Theobroma cacao* (Linn.), employed in making chocolate, are sometimes called chocolate nuts.

NUTATION, in astronomy, a small periodic gyratory movement in the direction of the earth's axis, by which, if it existed independent of the motion in precession, the pole of the earth would describe in the heavens a minute ellipse.

This ellipse would cover a space by its longer axis of 18.5", and by its shorter of 18.7", the longer axis being directed toward the pole of the ecliptic. The nutation period is a little less than 19 years (18.6), and corresponds to that of a revolution of the moon's nodes, with which it is directly connected. The effect of the nutation on the position of the stars is combined with the effect from precession; and as both are referable to the same physical agency for explanation, their further consideration will be found in the article **PRECESSION**.

NUTORACKER, a conirostral bird of the crow family, and genus *nucifraga* (Brisa.). The bill is longer than the head, strong, with culmen elevated and sloping to the entire tip; the lateral margins straight; gonys very long and ascending; nostrils basal, covered by frontal bristles; wings long and rounded, with the 4th and 5th quills longest; tail moderate, rounded on the sides; tarsi longer than middle toe, covered in front with broad scales; toes long, robust, and strongly scutellated; claws long, sharp, and curved. The common nutcracker (*N. caryocatactes*, Bris.), the best known species, is about 13 inches long, and the bill $1\frac{1}{2}$; it is about the size and shape of the European jay; the bill and feet are brownish black; the general color dull reddish brown, blackish brown above; the whole plumage, except the top of the head and the upper tail coverts, is marked with oblong white dashes margined with dark brown at the end, largest on the lower parts; lower tail coverts and tips of tail feathers white. This bird, rare in Great Britain, is common in the woods of the mountainous parts of Europe and Asia, especially in Switzerland, and in Russia; they are usually seen in pairs, but sometimes in flocks, migrating according to the season in search of larvæ and insects, which they obtain from trees in the manner of woodpeckers; they are also fond of the seed of fir trees, and of nuts, which they break by repeated strokes of the bill; they are said to devour small birds and eggs. The nest is made in a hole in a decayed tree; the eggs, 5 or 6, are yellowish gray with a few spots of light brown. This bold and familiar bird by its nearly straight bill seems to form a transition from the crows to the starlings, and in some respects to the woodpeckers, the last of which it also resembles in some of its habits.

NUTGALL. See **GALLS**.

NUTHATCH, a sub-family of tenuirostral birds of the creeper family, scattered over North America, Europe, and India and its archipelago. In the typical genus *sitta* (Linn.) the bill is entire, about as long as the head, slender, compressed, straight, and sharp-pointed, with the gonys long and ascending; nostrils in a groove, covered by bristles directed forward; wings long and acute, reaching nearly to end of tail, the 1st quill being very short, and the 3d and 4th about equal and longest; tail short, broad, and nearly even; tarsi about equal to middle toe,

strong and scutellated; toes long, the outer much longer than the inner, the hind toe the longest, and all armed with sharp and curved claws. Nearly 20 species are described; they prefer dense woods, where they run rapidly up and down the trunks and branches of trees in spiral circles, examining the crevices in the bark for spiders and insects; in winter they approach houses, and feed upon seeds, grains, nuts, and other vegetable food. The largest of the American species is the white-bellied nuthatch (*S. Carolinensis*, Gmel.), about 6 inches long, with an extent of wings of 11, and the bill along the gape $\frac{1}{2}$ of an inch; the bill is black, and iris dark brown; general color above ashy blue, with top of head and neck black; under parts and sides of head to above the eyes white; under tail coverts and tibial feathers brown; concealed primaries white. This is a bold, active, and familiar bird, though generally living in retired woods; the nest is made in the hole of a decayed tree; the eggs, 5 or 6, are dull white, spotted with brown at the larger end; the flight is rapid, and at times protracted; like others of the family, they are fond of roosting head downward. This species is spread over eastern North America to the highest central plains, replaced to the west by the *S. aculeata* (Cassin), which differs chiefly in the more slender bill; in the southern states two broods are hatched in a season; the notes are very nasal. The red-bellied nuthatch (*S. Canadensis*, Linn.) is $4\frac{1}{4}$ inches long, with an extent of wings of 8 inches; the upper parts are ashy blue, with the top of the head black, a white line above and a black line through the eye; chin white, and rest of under parts brownish rusty. The eggs are white, sprinkled with reddish dots. This very restless and active bird is spread over North America from South Carolina to Nova Scotia, from the Atlantic probably to the Pacific. Some remain all winter in the northern states, coming into the roads and farm yards in search of seeds. The brown-headed nuthatch (*S. pusilla*, Lath.), of the southern states, is sufficiently characterized by its name; the length is only 4 inches, and the extent of wings 8; it is lively, with a cheerful note, and is not at all shy. The California nuthatch (*S. pygmaea*, Vigors) is of the size of the last, which it much resembles, but the brown of the head has an olive green tinge; it is found from the Pacific to the Rocky mountains. The European nuthatch (*S. Europaea*, Linn.) is one of the largest of the genus, being 6 inches long, with an extent of wings of $10\frac{1}{2}$, and bill $\frac{1}{2}$ of an inch; the upper parts are bluish gray, with the throat and cheeks white, loreal space and a band behind the eye black; lower parts light reddish yellow, and sides brownish red. Its manners are the same; the tail is not used as a support either in ascending or descending trees. It is sometimes kept in wire cages for its activity, cunning, and drollery.—Other genera of the sub-family are *sittella* (Swains),

acanthisitta (Lafr.), and *dromodendron* (Gray). *Sittella* has a long, rather slender bill, slightly curved upward, and the tip emarginated; the wings reach beyond the tail, the 2d and 3d quills equal and longest; the tail is very short, and somewhat rounded. The species are peculiar to Australia. The nest is made of bark and lichens, attached to each other and to the branches of the highest trees by cobwebs, and from its small size and color is very difficult to detect; the eggs are 3 in number. In *acanthisitta* the bill is long and very slender, and slightly curved at the tip; the species are found in New Zealand, where they are seen on the bushes, searching the branches and leaves for insects and their larvae; the toes are long and very slender. In *dromodendron* the bill is long, straight, and sharp-pointed; wings long; tail long and rounded, with the shaft of each feather prolonged and rigid, as in the woodpeckers; tarsi robust. Gray alludes to a single species (*D. leucosternum*, Gould), found in the woods of Chili, S. of Valparaiso, and usually seen running up the trunks of lofty trees in pursuit of beetles and other insects.—The bill of the nuthatches is so powerful that it is used for breaking the shells of nuts, which they fix in a cleft or hollow, whence they are sometimes called nutcrackers, a name which properly belongs to the genus *nucifraga*. The French call them *torche-pots*, from their habit of plastering up with yellow clay (*torchis*) the apertures of holes in trees which are too open to make comfortable nests. Unlike the woodpeckers, they descend trees head foremost, in which they must find great assistance in the long hind toe.

NUTMEG, the kernel of the fruit of *myristica officinalis* (Linn.), or *M. moschata* (Thun.), of the natural order *myristicaceae*. The common nutmeg tree is a native of the Molucca islands, but is cultivated elsewhere in the East; it has been tried, though unsuccessfully, in the West India islands. It is a very beautiful tree, the foliage being of a rich dark green color, and though of slow growth attains a height of 20 or 25 feet. Level situations are most favorable for nutmeg plantations, as the roots take so slight a hold on the soil that on hillsides they are liable to be washed up by the heavy rains of the tropics. The young plants, obtained in the nursery from the seeds, are set in the ground in rows, and require constant weeding and watering, frequent manuring, and careful protection from the scorching heat of the sun. In the 7th year they commence bearing, and increase in fruitfulness to the 15th, when they reach their highest perfection. In the Moluccas they are said to continue prolific for 70 or 80 years. All parts of the tree are very aromatic. The fruit is smooth externally, pear-like in shape, and resembles a peach in size and color. It is produced in great abundance, and its maturity is evinced by the bursting of the rind, through which the brilliant scarlet of the mace and the bright brown shell in which the nutmeg is enclosed are seen. The

outermost portion is a thick fleshy pericarp, which when young is occasionally preserved as a sweetmeat. The next is the mace, a peculiar development of the stalk of the seed, which increases with its growth and finally envelopes it, called aril or arillus by botanists. Within it is the nutmeg enclosed in a shell. The tree is in bearing at all seasons of the year, the bud, blossom, and fruit being exhibited at the same time; consequently there is no particular season for gathering it, though the greatest harvest is in the months of September, October, November, and December. The average annual produce of a tree amounts to about 5 lbs. of nutmegs and 1½ lbs. of mace; and it is said that, should the price of nutmegs diminish very considerably, the raising of them would still be very profitable. The fruit is gathered by means of a barb attached to a long stick, and the outer covering being removed, the mace is carefully taken off, flattened by hand, placed on mats, and dried in the sun for 3 or 4 days, or over a moderate fire. By this process it becomes brittle, and the red tint is changed to orange, while it retains its aromatic odor and taste. It is then made up into packages, and kept perfectly free from moisture. The nuts are placed in their shells upon a hurdle over a slow wood fire, for a period of about 2 months. When dried sufficiently the kernel rattles freely in the shell, which is then broken with a mallet; the damaged or worm-eaten ones are thrown aside, and the sound ones are packed in very strong chests, in well sifted lime or in a mixture of lime and water. Another sort, called the long or wild nutmeg, the product of *M. tomentosa*, is sometimes imported, usually in the shell. It is nearly twice the length of the common nutmeg, and is of a very inferior quality. The common nutmeg is of a round or oval shape, gray color, hard and smooth or slightly furrowed. When grated or broken it presents a mottled veined appearance. The best are dense, heavy in the hand, and emit oil when pricked with a pin; when worm-eaten they feel light, and though the perforations may have been fraudulently filled up, the unsound ones can be easily detected.—The general qualities of the nutmeg and mace, except flavor, are the same. Their odor is fragrant and agreeable, and their taste pungent. Both are much used as a spice in cooking. They contain, according to Bonastre, fat oil 81.6 per cent., volatile oil 6.0, starch 2.4, gum 1.2, free acid 0.8, lignine 54.0. Nutmeg butter (*adeps myristica*), commonly called oil of mace, is a solid yellow fat, obtained from nutmegs by expression. The kernels are bruised into a paste, steamed in a bag, and then pressed between heated plates. It is imported in the form of cakes from the East Indies and from Holland. Most of that found in commerce is a factitious substance of fatty ingredients flavored with oil of nutmeg. In pharmacy nutmeg is sometimes employed to cover less agreeable tastes, and also as flavoring for drinks. When

taken in the quantity of 2 or 3 drachms, it has produced alarming effects. The oil is occasionally used externally as a stimulant. For further information, the reader is referred to a paper by Dr. Lumsdaine in the "American Journal of Science," Nov. 1851.—The importation of nutmegs into the United States for the year ending June 30, 1859, amounted to 879,830 lbs., valued at \$365,480; and of mace to 45,469 lbs., valued at \$16,478.

NUTRIA, the commercial name of the fur of the coypou (*myopotamus coypus*, Cuv.), a South American rodent of the beaver family. The dentition of the coypou is the same as in the beaver; the ears are short and round; the moustaches long and stiff, white with a few black hairs intermixed; the hind feet are fully webbed, but the external or 5th toe is separate from the rest; the mammae are 4 on each side, nearer the back than the abdomen, covered by hair. The length is 8 feet, of which the tail, which is long, round, and hairy, is one third. It is found in Chili and in the neighborhood of Buenos Ayres, living in the vicinity of water, and burrowing with the powerful fore claws in the banks of streams; it is an excellent swimmer, is easily tamed, and of gentle disposition, and will eat almost any kind of vegetable food; it has from 4 to 7 young at a birth. The fur is of 2 kinds: one of long reddish brown hair, which gives the general color to the animal; and the other brownish ash-colored, at the base of the former, extensively used, especially on the continent of Europe, in the manufacture of hats. These skins have been largely substituted for those of the beaver, and were formerly carried to Europe by hundreds of thousands in a single year; they are now getting less plentiful, as well as in less demand. The fur is sometimes called raccoonda by the furriers.

NUTRITION, the complicated process by which the component particles of the various tissues, disintegrated and removed by the vital acts of the organism, are constantly replaced by new matter capable of continuing the functions necessary to life; a perpetual reproduction, in which every part produces a tissue like itself, whether bone, muscle, or nerve, healthy or morbid structure. This requires a due supply of proper food, its digestion, absorption of the nutritive portion, conversion into healthy blood, and its circulation over the system; the effete matter is removed by the organs of excretion, or modified by the purifying action of the lungs. These points have been sufficiently dwelt upon in the articles ABSORPTION, ALIMENT, BLOOD, CHYLE, CHYME, CIRCULATION, DIETETICS, and DIGESTION. Each tissue possesses an elective affinity for certain constituents of the blood, which it appropriates to its own use in the process of conversion into organized material. During the whole period of active life, a demand for nutrition is consequent on every exertion of the vital powers, especially of the muscular and nervous forces. Of the modes in which the substitution of new

tissue takes place in the interstitial processes of nutrition, and in which the effete particles are removed in the interior of the system, our knowledge is as yet very imperfect. Though the formative power in healthy nutrition is not derived from the nervous system, it is often essentially modified by its influence. The character remaining the same, there may be considerable variation in the degree of activity of the nutritive processes, either in a part or the whole of the organism; in youth both the formative energy and the waste of the system are very active; as age advances, the former diminishes while the latter does not increase; local instances have been alluded to under **ATROPHY** and **HYPERTROPHY**. In healthy nutrition, an adult person is maintained for years with the same general outline of form and feature, of size, and perhaps of weight, while at the same time the particles which compose the different parts of the body are undergoing a continual process of decay and renewal; and such is the exactness of the reproduction, that the body is one and the same through life. (See **BONE**, and **MUSCLE**.) Nutrition is actively performed in the process of reparation by which losses of substance from accident or disease are made good; this is most active in the lower animals, but limited in man to such parts as the bones, muscles, tendons, nerve fibres, vessels, epithelial tissues, and blood. Inflammation is not necessary to this process, as was generally believed until near the 2d half of the 19th century, though unfortunately attending most cases of wounds. Dr. Macartney was the first to show that the occurrence of inflammation is injurious to such reparation. There are many abnormal forms of the nutritive process, in which the tissues produced are different from those they ought to replace. In inflammation the natural relation between the blood and the tissues is disturbed; the formative activity is lessened, and the plastic components of the blood are increased and effused in a more or less unorganizable condition; the calibre of the vessels is changed, and the rate of the movement of the blood altered. Common and fatal forms of abnormal nutrition are seen in the imperfectly organized products of scrofula and the aplastic deposits of tubercle, and in the cancerous and fungous growths different in character from the normal tissues.

NUTTALL, THOMAS, an American naturalist, born in Yorkshire, England, in 1786, died at Nutgrove, St. Helen's, Lancashire, Sept. 10, 1859. He learned the trade of a printer, and about the beginning of the present century came to the United States, where he soon engaged with ardor in the study of natural history. His researches led him to extensive travels, in the course of which he visited nearly all the states of the Union, explored the great lakes and the upper branches of the Mississippi, and in 1810 ascended the Missouri as far as the Mandan villages. In 1819 he explored the Arkansas river and the neighboring regions,

and published an account of his travels, entitled "A Journal of Travels into the Arkansas Territory" (Philadelphia, 1821). He travelled also on the Pacific coast, and published several papers on the shells and plants of that region. From 1822 to 1834 he was professor of natural history in Harvard college, and curator of the botanical garden. Subsequently he returned to England, and spent the rest of his life on the estate of Nutgrove, which was bequeathed to him on condition that he should reside upon it. His principal works are: "Manual of the Ornithology of the United States and Canada" (2 vols. 12mo., Boston, 1834), and "The North American Sylva" (3 vols. royal 8vo., Philadelphia, 1849).

NUX VOMICA, the name of a drug consisting of the seeds of the *strychnos nux vomica* of botanists. This is a middle-sized tree of the East Indies, with a crooked trunk and smooth ash-colored bark, round, shining, smooth, ribbed leaves, small, greenish white flowers having hypocrateriform corollas with valvate lobes, 5 stamens with very short filaments, and a berry-like fruit of the size of a small apple, with a brittle shell and a white, gelatinous pulp, in which the discoidal seeds are lodged. It belongs to the natural order *loganiaceae*; a more venomous order it would be difficult to name. The wood of the *nux vomica* tree is exceedingly bitter, particularly that of the root, which is used to cure intermittent fevers and the bite of venomous snakes. The pulp of the fruit seems to be innocent, and is eaten by birds. The seeds, however, are extremely poisonous, notwithstanding which they are employed in adding more intoxicating properties to spirituous liquors and to beer. The drug, according to Lindley, in large doses produces extraordinary rigidity and convulsive contraction of the muscles previous to death. In very small and repeated doses it promotes the appetite, assists the digestive process, increases the secretion of urine, and sometimes acts slightly upon the bowels. It was mainly introduced into practice by the homoeopaths in many bilious and nervous headaches, chronic constipation, dyspepsia, &c. In regular practice *nux vomica* is used in the treatment of paralysis, nervous affections, dyspepsia, pyrosis, impotence, and dysentery. The seeds, rasped or filed, have been used to destroy dogs, cats, hares, foxes, rats, and vermin, under the vulgar name of ratsbane. The active principle, which is so poisonous and which is called strychnia, has been detected in several other species of the same genus of plants, and is mainly used in the regular medical practice.

NYANZA, a great lake of central Africa, discovered by Capt. Speke, Aug. 8, 1858. It is called Ukerewe by the natives, and was named Victoria by Capt. Speke, Nyanza, the appellation by which it is now commonly known, being the native word for lake. Its S. extremity lies about 150 m. S. of the equator, and it was conjectured by Speke, from various

accounts which he obtained from the natives, that it extended at least to lat. 1° N., in long. 31° or 32° E. Those whom he questioned supposed that it stretched to the end of the world. There was no means of ascertaining its breadth, for it was so broad that one could not see across it, and the only communication between the E. and W. shores was by occasional canoe parties coasting along the S. end. "The lake has the credit," says Speke, "of being very deep, which I cannot believe. It certainly bears the appearance of the temporary deposit of a vast flood overspreading a large flat surface, rather than the usual characteristics of a lake or inland sea, lying in deep hollows, or shut in, like the Tanganyika, by mountains. The islands about it are low hill tops, standing out like paps on the soft placid bosom of the waters, and are precisely similar to those among which I have been travelling; indeed, any part of the country inundated to the same extent would wear the same aspect. Its water appears, perhaps owing to the disturbing influence of the wind, of a dirty white color, but it is very good and sweet." At the S. end there are two islands of considerable size and a group of islets, which the discoverer named the Bengal archipelago. A small river enters it at this end, and on the W. shore it receives several streams from the mountain range which Speke calls the mountains of the Moon; while on the E. it is supposed to be fed by a large river which Dr. Krapf describes as flowing N. W. from the W. base of the snowy Kania. Speke entertains no doubt that the Nyanza is the source of the Nile. Its elevation is about 3,738 feet above the sea, while that of the bed of the Nile in lat. $4^{\circ} 44'$ N. was ascertained by Knoblecher to be 1,605 feet, a difference of elevation more than sufficient to account for the rapids in the upper part of the Nile, which have thus far baffled the efforts of all explorers to follow the stream to its source. For an exposition of Speke's reasons for this supposition, see "Blackwood's Magazine," Oct. 1859.—It is a remarkable fact that two lakes resembling Tanganyika and Nyanza, occupying the same relative positions, but some degrees too far south, were laid down on a map published at Amsterdam in the French edition of Dapper's "Description of Africa, Egypt, &c.," in 1686. The geographer Ptolemy also, in the 2d century A. D., mentions two lakes S. of the equator as the sources of the Nile. (See NILE.)

NYASSA, NIASSI, NYENYESI, NYANJI, or MARAVI, a lake of central Africa, the extent of which is not precisely known. Its S. extremity lies in lat. $14^{\circ} 23'$ S., long. $35^{\circ} 30'$ E., or about 400 m. from Mozambique, and it is supposed to extend northward to lat. 10° S. It appears to be of great length, N. and S., in proportion to its breadth; and it has even been conjectured that it is a large river, the head stream of which passes near Cazembe's Town, at the S. end of Lake Tanganyika. According to the natives, it is so narrow at its southern opening that people

on the opposite shores can call to each other. A short distance further N. there is a ferry between the villages of Msauka on the W. and Mjanga on the E., the boats making 2 or 3 trips a day. At the next ferry two days are occupied in crossing, the intervening night being passed on the island of Mount Mbaazuru. Between Zenga on the W. shore and Gnombo on the E., still further N., the passage takes from sunrise to sunset, and is never attempted except in a perfect calm. Above this, at a part of the lake where it bends toward the W. and increases greatly in width, the people of the opposite shores have no communication with each other. From the S. extremity of the lake flows the river Shire, which unites with the Zambesi about 60 m. from the sea. The E. shore is inhabited by the Wajania or Wanguru, who occupy an extensive tract of country, and the W. shore by the Wamaravi (people of Maravi), Wanjanja, Wakamunda, Wamwera, and Wakumbodo.—The lake was first laid down on Portuguese maps as early as 1546, but no precise information concerning its position was obtained until the time of Manoel Godinho (1663), who learned in India from a Portuguese traveller that it communicated with the Zambesi through a river which he called Zachaf. Gamitto (1831) states its width to be 33 English miles, but the current was so strong that boats were 2 or 3 days in crossing, and it was so shallow that they were propelled with poles. Dr. Livingstone, in his "Missionary Travels in South Africa," speaks of meeting a Senhor Candido at Tete on the Zambesi river, who had visited the lake and crossed it at a narrow part, being 36 hours on the passage. His canoe was pushed by poles all the way. The surrounding country he described as a level plain covered with grass and destitute of wood. He regarded the lake as no more than an expansion of the river Nyassa, which comes from the N., and issuing at the S. end of the lake passes into the sea on the E. coast under another name. This may be the river Ruvuma, whose mouth is near Cape Delgado, and which Dr. Krapf was told came from a large inland lake. Dr. Livingstone has since reached the Nyassa by ascending the Zambesi and Shire, and is now (1861) engaged in the exploration of the surrounding regions. He has found a rich cotton-growing country in the vicinity, which seems to be accessible by the river. From the point where the Shire issued the lake appeared to stretch N. N. W., and in the distance was seen an island, which may be the mountain above alluded to. About the first months of 1860 the lake was also reached by Dr. Albrecht Roscher of Hamburg, who was attacked by two of the natives on the E. shore and killed by poisoned arrows. The news was carried to Zanzibar by his servants.

NYBORG, a fortified town of the island of Funen, Denmark, on the Great Belt; pop. in 1851, 8,059. It is defended by a strong citadel, and is the place where the sound dues were

paid by vessels passing through the Great Belt. It contains ship building yards.

NYCTALOPIA (Gr. *νύξ*, night, a privative, and *ὤψ*, the eye), night blindness. Nyctalopia has been used in different acceptations by various authors, sometimes as signifying blindness occurring only at night, at others as occurring in the day; the former, or night blindness, is now the general and accepted signification among the best medical authorities. The disease varies in intensity; in mild and recent cases there being only a greater or less indistinctness of vision after sunset, while in others the patient is entirely unable to distinguish objects by the light of the moon or by artificial light, or even to see a lighted candle placed directly before the eyes. During the day the pupils move naturally, but after night-fall they remain usually dilated and sluggish or motionless. In old cases they are occasionally observed to be contracted. The disease is said to be sometimes congenital and hereditary; more commonly it is produced by continued exposure to the bright light of the sun during the day, particularly when the strength is impaired by over-fatigue, watching, and a faulty diet. It is of common occurrence in warm and tropical climates, particularly among strangers from a more temperate region. It sometimes seems to be produced by the reflection from snow. Dr. Guthrie ("Edinburgh Medical Comment," decade ii., vol. ix., p. 268) says: "I was lately desired to give an opinion on a curious phenomenon that happened last war in Finland, where a Russian detachment, ordered to attack a Swedish post during a light night in spring, had like to have mistaken one another for enemies, and occasioned bloodshed, owing to some hundreds in the column being blind after sunset. The complaint seized the soldiers in the spring, when the nights, from the short absence of the sun and the strong reflection of the snows, must have been very fatiguing to the eyes, at a period of much martial vigil and alarm; surprises on both sides being then very frequent, more especially nocturnal." Avoidance of exposure to excessive light is in general all that is necessary to obtain a cure. If the disease be accompanied by any gastric or other derangement, this should of course be attended to. When the complaint has proved obstinate, a succession of blisters to the temples has been found beneficial.—The term *hemeralopia*, day blindness, has been applied to a defect of vision the opposite to *nyctalopia*. Beyond the *photophobia* common to

those who have been long habituated to darkness, to albinos, and to children laboring under strumous ophthalmia, this has no real existence.

NYERUP, NASMUS, a Danish antiquary, born in Finen in 1759, died June 28, 1829. He was educated at Copenhagen, where in 1796 he became professor of literary history and university librarian. He wrote several valuable bibliographical works, but his reputation rests chiefly on his antiquarian compilations, of which the most noteworthy is his "Historical and Statistical Exhibition of the Condition of Denmark and Norway in Ancient and Modern Times" (2 vols., 1802-'6); and more especially on his numerous writings in regard to the ancient Danish language and literature.

NYMPH. See **CHRYSLIS**.

NYMPHÆA. See **Cos**.

NYMPHS, in Greek and Roman mythology, inferior female divinities, personifying or presiding over various departments of nature. The *Oceanids*, daughters of *Oceanus*, and the *Nereids*, daughters of *Nereus*, were salt water nymphs, the latter dwelling in the Mediterranean, and especially in the *Ægean* sea. The *naiads* were nymphs of fountains and other fresh waters, those presiding over lakes being also called *limniads*, and those over rivers, *potamids*. The nymphs of mountains and grottos were called *oreads* or *oretiads*; of forests and groves, *dryads* and *hamadryads*; and of vales, glens, and meadows, *naphææ* and *leimoniads*. They were also named from certain races or localities with which they were associated, as *Nysiads*, *Diclonids*, *Lemniæ*, &c.; and were subdivided into still other classes, with names and attributes almost innumerable. Sacrifices were offered to the nymphs of such productions of nature as abounded in their several haunts. They were not immortal, though always youthful, and often perished with the objects of their care; or the object was said to languish and die when the guardian nymph forsook it. The demigods and heroes of antiquity were fabled to have been nourished by nymphs, and many wise men to have been inspired and instructed by them; and in general they watched with solicitude over the fate of mortals. They participated in the councils of the gods on *Olympus*, and often appear in company with the higher divinities, as for example with *Apollo*, *Bacchus*, *Venus*, *Pan* and *Silenus*, and with *Diana*. The poets and artists of antiquity so represented them, giving them always youth, a negligent and wild beauty, light flowing robes, and long floating hair.

O

O, the 15th letter and the 4th vowel of the English alphabet. It is pronounced by pointing the lips and forming with them an opening resembling the letter itself. Phonet-

ically it occupies a position between A and U, the sound passing gradually into that of the former letter in proportion as the lips are more opened, and into that of the latter in

proportion as the opening is contracted. With both these it is sometimes interchanged. The English *one*, *two*, *stone*, are pronounced in Scotland *ane*, *tea*, *stane*; and in the words *done*, *won*, *come*, *soma*, *o* is written where *u* is pronounced. O and U appear indeed to have had a common origin, and it has been supposed that the old Greek alphabet did not contain *upsilon* (*υ*), while the Etruscan had U but not O; hence the frequent occurrence of O in Greek and of U in Latin. O is also interchanged with the Greek and Latin long *α*, equivalent to the English *a* (Gr. *αηρ*, Lat. *cor*); with *ou* (French *tout*, Lat. *totus*); *uo* (especially in Italian, as in *cuore*, Lat. *cor*); *eu* (French *lieu*, Lat. *locus*); *au* (French *or*, Lat. *aurum*); *oa* (the English *boat* having probably been originally pronounced *bo-at*, Ger. *Boot*); *ue* (Span. *bueno*, Lat. *bonus*); *ea* (*cleave*, *clove*); *i* (*write*, *wrote*); *ei*, pronounced as the English long *i* (Ger. *nein*, Eng. *no*); *ie*, pronounced as the English *ee* (Ger. *niemand*, Eng. *none*); and short *e* (Lat. *vella*, *colo*; *vermis*, Eng. *worm*). In English O has 4 sounds: long, as in *note*; short, as in *not*; obscure, as in *occur*; like *oo*, as in *more*, *wolf*. There are also some exceptional cases in which it takes the sound of short *u*, as instanced above; of broad *a*, as in *lord*; and of short *i*, as in *women*. It forms the following diphthongs: *oa*, sometimes equivalent to long *o*, as in *coal*, or broad *a*, as in *broad*; *oe*, sounded like long *o* in *foe*, *oo* in *canoe*, and long *e* in *fetus*; *oi*, having its proper sound as in *voies*; *oo*, long as in *soon*, short as in *good*, like long *o* as in *floor*, or like short *u* as in *flood*; *ou*, as in *house*, or like short *u* in *double*, *oo* in *soup*, *could*, long *o* in *though*, short *o* in *hough*, and broad *a* in *ought*; *ow*, sounded like *ou*; and *oy*, like *oi*. The use of O is next in frequency to that of A. It is employed particularly to express admiration, warning, compassion, and entreaty, and occurs as an interjection in all languages.—In inscriptions, O. stands for *optimus*. As a prefix to Irish names, it signifies "son of;" thus, O'Connor is equivalent to son of Connor. In freemasonry it denotes Orient; in French geography, *ouest*, west; in German geography, *Ost*, east. In Greek numeration it stood for 70, and in the middle Latin for 11, or with a dash over it, *Ō*, for 11,000.

OAJACA, or OAXACA, a state of the Mexican confederation, bounded N. E. by Vera Cruz, E. by the territory of Tehuantepec, S. by the Pacific, W. by Guerrero, and N. W. by Puebla, and extending from lat. 15° 40' to 18° 30' N., and from long. 95° to 99° W.; area, 84,948 sq. m.; pop. 581,962. There are several small bays upon the coast. The principal river is the Rio Verde, which waters the extensive valley of Oajaca. The surface is uneven and mountainous, the state being traversed from N. W. to S. E. by the cordillera of Anahuac. It is one of the most beautiful districts of Mexico. There are mines of gold, silver, and lead; and all the rivers have gold in their sands. In the mountainous districts, and more especially

in the spacious valleys which are situated from 2,500 to 6,000 feet above the level of the sea, the soil and climate are equal to any on the globe. The productions are wheat, indigo, cochineal, cotton, sugar, honey, cacao, plantains, and other fruits. The inhabitants are chiefly Indians. The number of schools is about 700, attended by upward of 80,000 pupils; and the number of young persons attending colleges is about 200. "The intendency of Oajaca," says Humboldt, "is one of the most delightful countries in this part of the globe. The beauty and salubrity of the climate, the fertility of the soil, and the richness and variety of its productions, all minister to the prosperity of the inhabitants; and this province has accordingly been from the remotest period the centre of an advanced civilization."—OAJACA, the capital of the above described state, is situated on the left bank of the Rio Verde, 200 m. S. S. E. from Mexico, on the site of the ancient Huaxyacac; pop. about 25,000. The town is built in an oblong form, nearly 2 m. by 1½ in extent, including the suburbs, which are full of gardens and plantations of nopal, on which tree the cochineal insect subsists. The streets are wide and well paved; the houses are of two stories and built of freestone. There are several handsome and richly decorated churches and monasteries, a town house, a bishop's residence, and manufactories of silk, cotton, sugar, and chocolate.

OAK (*quercus*, Linn.), the name of a noble group of plants of the natural order *cupulifera*, embracing about 150 species, and confined for the most part to the northern regions of the globe. Scarcely known in the southern hemisphere, they reach their most southern limits in the islands of the Indian archipelago, and occur on the eastern shores of Asia and on the Himalaya mountains. In North America they range from Canada, through California and Mexico, to the isthmus of Darien. Each section of the globe where they appear has species of its own, those of the East being seen nowhere else, and the numerous North American kinds being peculiar to that country. The oaks may all be considered trees, though varying greatly in size; they are chiefly large, the leaves alternately placed upon the branches, falling off at the end of summer, or else persistent and even evergreen, conduplicate in the leaf bud, the scales imbricated. The leaves vary greatly in different species, from the lanceolate, cordate, entire, lobed, and sinuate-shaped, to even the pinnatifid forms. In all the species the flowers are inconspicuous, without corolla, and generally appear before the foliage expands; they are monœcious, the male flowers in long tassels or aments of jagged scales, at the base of each one of which are placed 5 to 20 stamens; the female flowers are usually bud-shaped, their ovaries enclosed in an involucre surrounded by a toothed calyx; they contain from one to several ovules, only one of which arrives at maturity. The

fruit is a one-celled nut, wholly or partially enclosed in a cup, called the cupule, and this with the enclosed nut is termed the acorn. Structurally the cupule is only a modified involucre, composed of a great many small bracts growing together at their edges and more or less free at their tips, which, when extended to an attenuated length, gives the cupule a mossy appearance, a character belonging to several species.—The oaks of Europe, northern Asia, and Barbary have been arranged into 3 groups; and we shall in this article adopt a similar geographical view of the most prominent species. Belonging to the first, or forest oaks, is the common oak (*Q. pedunculata*, Linn.), a tree from 50 to 100 feet in height, with spreading tortuous branches and spray, and with a head broader than it is high, especially if the tree stands singly and alone. The leaves are deciduous, oblong, smooth, dilated upward, sinuses rather acute, lobes obtuse; the acorn borne upon a long peduncle, its nut oblong. Many curious varieties are known in Europe under cultivation. This is the commonest oak in England, and is considered the true British oak, whose timber is best suited for naval purposes, on account of its durability and hardness; there are however other species equally valuable. The length of the footstalk which supports the acorn is a most observable and remarkable fact, the more especially as the footstalk of the leaf is as observably short. The sessile-flowered oak (*Q. sessiliflora*, Salisbury) is the other British species, whose timber has proved remarkable for durability, as is known from its use in the construction of some of the oldest buildings in England. In size, the species compares favorably with the former; and indeed, according to most authors and observers, there is little or no difference in magnitude and general appearance between the entire full-grown trees of both species. Its wood so much resembles chestnut, that the trivial name of the chestnut oak has been applied to it; and various other names have obtained in different portions of Europe, as indicative of variations or fancied resemblances of parts of the tree, or of its wood. The leaves of the sessile-flowered oak are borne upon long petioles; they are deciduous, oblong, smooth, with opposite sinuses rather acutely indented, though the lobes are obtuse; the fruit is sessile and the nut oblong. A third species, native of southern Europe, is the *Q. pubescens* (Willd.), with smaller leaves, which are often very woolly on the under side, the lobes much sinuated. It is a majestic tree, resembling the sessile-fruited oak, but having an inferior kind of timber. The tanzin of Persoon (*Q. Pyrenaica*, Willd.) is a small, scrubby tree, growing on poor, sandy soil in southern France, having grayish-colored leaves and wood of little value.—The evergreen oaks are represented in Europe by the holm oak (*Q. ilex*, Linn.), a large shrub or low middle-sized tree, according to soil and situation, native of southern Europe, northern Africa,

Cochin China, and other parts of Asia. It has been long cultivated in British gardens for its beauty. The bark of its trunk is even; its leaves ovate, oblong, coriaceous, entire or serrated, hoary beneath; the acorns ovate and borne upon short stalks, ripening the 2d year, but bitter and unfit for food. It prefers the neighborhood of the sea, growing singly or in clumps in a wild state. Its wood is very hard, tough, heavy, and of excellent quality, where its weight is not an objection. The sweet-acorn oak (*Q. gramuntia*, Linn.) is also an evergreen species, with elliptical, coriaceous, entire or serrated, very obtuse leaves, which are downy beneath; the acorns cylindrical, elongated, edible, and when in perfection as good as chestnuts. The cork tree (*Q. suber*, Linn.) in form is said to be much more beautiful than the common evergreen oak, and in districts suited to it attains a great height. It is found throughout all the warm parts of Spain, and most abundantly in Catalonia and Valencia. It is this species that furnishes the cork of commerce, which is a soft, spongy growth of its bark. The kermes oak, producing the "scarlet grain," is the *Q. coccifera* of Linnaeus, a low bushy shrub, resembling a holly in miniature, with elliptical, oblong, rigid leaves, which are smooth on both sides, having spreading, bristly, spinous teeth, the fruit borne upon peduncles, the nut ovate, the cup with spreading, pointed, somewhat recurved scales. It occurs in S. Europe and the Levant, flowering in May. The value of the insects which feed upon the juices of its bark has been known among the eastern nations from the earliest ages, but since the discovery of America the cochineal has greatly supplanted the kermes as an article for dyeing.—The mossy-cupped oaks are peculiar in their deeply pinnatifid leaves, the long narrow scales of their cups, and their equally long, deciduous stipules. The Turkey oak (*Q. cerris*, Linn.) is exceedingly common all over Europe, where it seems to form some of the finest specimens. Its leaves are deciduous on very short footstalks, oblong, deeply and unequally pinnatifid, hairy beneath, the lobes lanceolate, acute, somewhat angular, stipules longer than the footstalks, and cup hemispherical with long, loose, hairy scales. Under cultivation it shows a great tendency to sport, and many curious varieties are constantly occurring. The abundance of the silver grain in the wood gives it a beautiful mottled appearance, and when grown under favorable circumstances the timber is considered equal to that of any other species. The vallon oak (*Q. agrilops*, Willd.) yields the acorns called vellani or vallon in commerce, used extensively for tanning. This tree is indigenous in the islands of the archipelago and throughout Greece, and grows to a large size there. Its leaves are ovate oblong, with bristle-pointed, tooth-like lobes, hoary beneath; the cup of the acorn is very large, hemispherical, with lanceolate, elongated, spreading scales; nut large,

short, and a little hollow at the top. The acorns are in great demand for tanning, being said to contain more tannin in a given bulk of substance than any other vegetable. The more substance there is in the husk or cup, the better. According to Miller, the *Q. agilops* is one of the most splendid species, and can be recommended to all lovers of fine trees.—Asia Minor has several species of oaks, of which perhaps one of the most important is the gall oak (*Q. infectoria*, Willd.), a very common species, whose branches are attacked by a kind of *cynips*, causing the formation of the gall nuts of commerce. The leaves of this species are ovate oblong, very smooth on both sides, somewhat sinuated, deciduous; the acorn sessile, its cup tessellated and nut elongated. The royal oak (*Q. regia*) of Koordistan is said to be a noble species, with very large, heart-shaped, wavy leaves, having coarse, unequal serratures, green and shining on both sides, each of the lobes terminated by a conspicuous bristle. From the manna oak (*Q. mannifera*) the Koords obtain a sweet mucilaginous substance by steeping the branches and leaves in boiling water, at the hottest season of the year, and afterward evaporating the water. This substance, made into cakes, is sold in the market as the "sweetmeat of heaven."—The oaks of the Himalaya, according to travellers, are abundant, and Dr. Wallich obtained many distinct species. In his *Planta Asiatica Rariores* he describes a magnificent species whose timber is greatly prized by the natives; its trunk frequently attains 80 to 100 feet, and its girth at 6 feet from the ground is 14 to 18 feet, and sometimes of even larger dimensions. It is the marking-nut oak (*Q. semecarpifolia*), with obovate, obtuse, coriaceous, entire leaves, heart-shaped at base and downy beneath; acorns solitary or in pairs, depressed at the point, and about twice as long as the shallow, scaly cups. Another species, very like the evergreen oak of Europe, is the Himalayan ilex (*Q. incana*), said to be a beautiful tree. The woolly-leaved Nepal oak (*Q. lanata*) is one of the handsomest yet discovered, and is found growing wild with the tree rhododendron of these mountains. A beautiful Chinese species in mountainous places is the *Q. Chinensis*, with sessile, globose acorns, whose cups are composed of hairy lanceolate scales, the outer of which are reflexed and longer than the nut.—Several species of oaks have been noticed in Java, Sumatra, and the Molucca islands, having entire, lanceolate, broad-lanceolate, ovate, or oval-oblong, acuminate, or narrow-lanceolate leaves, and acorns of curious forms and size.—The North American oaks have received the attention of the Michaux, father and son. According to Mr. G. B. Emerson, in his "Report on the Trees and Shrubs of Massachusetts" (Boston, 1846), the most natural arrangement of them seems to be that adopted by the elder Michaux. He divided them into two sections according to the character of the leaves; the first comprising those

species whose leaves are destitute of flexible points or bristles; the second, those with leaves whose segments are mucronate, or terminate in bristles. A very important difference is also observed in the length of time required for the blossom to bring its fruit to maturity. Most of the oaks of Europe blossom in the spring, and mature their fruit the same season; and this is the case with those American oaks which belong to the first section. In those included in the second, on the contrary, the fertile blossom makes its appearance in the axil of the leaves on the new shoot, and remains a whole year without change. In the spring of the 2d year, after the new shoot has been produced, and new barren and fertile flowers are developed, it is, probably for the first time, fecundated, and then begins to increase and bring its fruit to maturity 18 months after its first appearance. In this case the fruit seems not to be axillary, as the leaves of the previous year, in whose axils it grew, have fallen. Most of the trees which belong to the first section possess greater value, on account of the excellent properties of their timber, than those of the second.

1. Of the first section, the white oak (*Q. alba*, Linn.) sometimes reaches to the height of 60 or 80 feet or more. Its limbs are very large, and diverge at a very large but not uniform angle from a broad, gnarled, massive juncture. The bark on the trunk is of a very light ash color, whence it is universally known, though always called "white oak." Its leaves are on short petioles 4 to 6 inches long and 2 to 3 wide, pubescent beneath when young, but smooth when old; above of a light shining green color, below paler or glaucous, and almost coriaceous in substance; deeply divided into lobes, about 8 or 4 on each side, each of which is oblong, rounded or obtuse, rarely subdivided. In different localities the leaves widely vary, becoming sometimes very narrow. The flowers are upon a very long slender thread, each calyx containing 4 to 7 stamens; the acorns grow single or in pairs fixed to the year's shoots; usually they are about an inch long, ovoid, oblong in a shallow and flattened cup. The nut is of a pleasant sweet taste, and when roasted agreeable to the palate. This species has a wide distribution through the United States, and is a well known and valuable tree; it furnishes the best ship timber, and is used in the making of wheels, casks, hoops, &c. Its bark is valuable to the tanner, and its wood, when used for fuel or burned for charcoal, is highly prized. It can be recommended for an ornamental tree on account of its picturesque outline and general contour, especially after it has attained an old age. The over-cup white oak (*Q. macrocarpa*, Mx.) is a fine erect tree of medium height, irregularly branched, and with luxuriant foliage. Its leaves, on short footstalks, 6 to 7 inches long and 3 to 4 inches wide, are pear-shaped in their general outline, deeply and irregularly sinuate-toothed, smooth and dark green above, much lighter beneath; the

acorns are very large, their nuts enclosed for more than half their length in a cup covered with very prominent scales, and bordered by a conspicuous fringe of long, flexile threads. This species is likewise called in some districts the pin oak, on account of its wood being used in making pins or treenails, possessing stiffness and solidity, and a similarity to that of the white oak, but preferred for fuel. It ranges along rivers and in dry woods from western New England to Wisconsin, Kentucky, and southwestward. The post oak (*Q. obtusiloba*, Mx.) is a small tree with very durable wood, resembling that of the white oak; its leaves are stiff, coriaceous, divided at one third their length by a deep sinus on each side; the upper portion is of three broad, obtuse, divergent lobes; the acorns are nearly sessile on very short footstalks; the nut, set in a grayish, broad cup, invested with numerous very smooth, close scales, is small and sweet. This tree is used for posts, whence its common name; its timber is likewise employed for knees in ship building, and much esteemed for fuel; for durability it is considered inferior only to the live oak, and when of sufficient size is valued for ship timber. Its range of growth is from the coast of Massachusetts to Wisconsin and southward. The swamp white oak (*Q. bicolor*, Willd.) is considered by Prof. Gray to be a variety of the swamp chestnut oak (*Q. prinus*, Linn.), growing throughout the United States in low, moist grounds. In warm and sheltered situations at the north, it is a beautiful and neat tree; but exposed to a north or east wind, it becomes ragged and homely. Its leaves are unequally and deeply sinuate-toothed, bright green above, and whitish downy beneath; the acorns are an inch or more long, the cup with pointed and sometimes awned scales, which form a fringed margin; the nut has a sweet kernel. The wood is of a brownish color, heavy, compact, and fine-grained, possessing great strength and elasticity; it is sometimes preferred by boat builders to that of the white oak. The yellow chestnut oak (*Q. castanea*, Willd.) is a middle-sized tree in the rich woods from western New England to Wisconsin, and southward. Its leaves are shaped more like those of the chestnut tree than any other of the oaks; it has a small ovoid or oblong nut in a hemispherical cup, with thin, small, appressed scales. The dwarf chestnut oak (*Q. prinoides*, Willd.) seldom attains a greater height of stem than 5 feet, and frequently rises no more than 2 to 3 feet. It is a pretty species, with small acorns, which are usually produced in abundance, and which are eaten with avidity by wild animals. Its bark is very bitter, and might be used for tanning by employing the branches and twigs. It thrives in sandy soils from New England and New York southward. 2. Of the second section, the leaves of which are mucronate, fruit sessile, and fructification biennial, may be cited the black oak (*Q. tinctoria*, Bartram), distinguished from all

other species by the rich yellow or orange color of its inner bark, constituting the quercitron of the dyers, and by the black color of the external bark upon the lower part of the trunk of the tree. Its wood is much used as a substitute for white oak, being second to it in quality; its grain is close and rather fine, and possesses great strength. The range of this species seems to be extensive throughout the United States. The scarlet oak (*Q. coccinea*, Wangenheim) is a large tree, whose long-petioled, shining leaves, turning bright scarlet in autumn, afford the trivial name it bears. It may be distinguished from the black oak by its more deeply cut foliage, and by the brighter and lighter hue of the leaves. It abounds in the eastern part of the state of Massachusetts; and in the middle, southern, and western states it forms one of the tallest species of the oak family. Its wood is much employed for fuel; but its bark, being comparatively thin and not abounding in tannin, is less valuable than that of the preceding species. The red oak (*Q. rubra*, Linn.) is the most northern species of this section. It is common in all the New England, middle, and southern states as far as Georgia, and on the western slopes of the Alleghanies. It is a good-sized tree, with reddish, very porous, and coarse-grained wood, of little value as timber. It flourishes in all situations, and grows with rapidity; its foliage and trunk are very beautiful, and its dimensions often extraordinary. The annual shoots or suckers from the stump sometimes grow 6 feet high; and its facility in growing from the acorns might recommend it for covering poor soils. The pin oak or swamp Spanish oak (*Q. palustris*, Du Roi) is a very handsome middle-sized tree, with a light elegant foliage, the sinuses of its leaves reaching $\frac{1}{2}$ of the way to the midrib; the acorn is globular, scarcely half an inch long. It may be found along streams in low grounds from southern New York to Wisconsin. Its timber is considered better than that of the red oak. The bear oak (*Q. ilicifolia*, Willd.), better known as scrub oak, is a small species 6 to 8 feet high, growing on rocky hills and gravelly knolls from New England to Ohio and western Virginia. Its acorns are ovoid, of a deep orange color at base as well as inside, and are abundantly produced; they are devoured with avidity by bears, which circumstance affords one of the trivial names applied to the species. The Spanish oak (*Q. falcata*, Mx.) is either a small or a large tree, from 80 to 80 feet high, growing upon dry and sandy soil, with an extremely variable foliage, and to be met with from New Jersey and Pennsylvania southward. Its wood is similar to that of the red oak, and its timber is of little value. From Virginia and southward to Florida is found the water oak (*Q. aquatica*, Catesby), a tree 40 feet high, with glabrous and shining leaves, obovate-spatulate or narrowly wedge-shaped in outline, with long, tapering bases; the acorns globular, the

cup saucer-shaped and hemispherical, the scales fine and close. Its trunk is clad in a smooth bark, which in the oldest trees is slightly furrowed; the timber is very tough, but less durable than that of some other species. The black jack or barren oak (*Q. nigra*, Linn.) has similar leaves, but they are more broadly wedge-shaped, rounded or cordate at base, slightly 3-lobed at the summit, shining above, rusty pubescent beneath, 4 to 9 inches long; the acorn ovoid, short, the cup top-shaped, coarse-scaly, covering half the nut. It occurs in dry barrens from Long island, N. Y., to Illinois and southward; its trunk is 8 to 20 feet high, with a pretty close timber, which is of little use in the arts because generally decayed at the heart, and too easily rotting on exposure to the air; its principal use is for fuel.—The evergreen or live oaks are represented in the southern states by the live oak (*Q. virens*, Aiton), occurring on the coast of Virginia, and increasing in value as it is found more southward. Its leaves are obtuse, oblong or elliptical, hoary beneath; the acorn oblong, with a top-shaped cup. This species sometimes grows to a great size; though usually it does not afford large timber, its wide and branching summit makes valuable knees for the ship yard; the bark, which is excellent for tanning, is only incidentally employed; the acorns are said to be remarkably sweet. The upland willow oak (*Q. cinerea*, Mx.) is a small tree with acute lance-oblong leaves, and of a white downy hue beneath; its acorn is globular, the cup saucer-shaped. It occurs in pine barrens in Virginia and southward. It is considered a very inferior sort of tree, and not even of much value for fuel. The true willow oaks, or those having deciduous, entire, narrow leaves, are represented by the willow oak (*Q. phellos*, Linn.), a tree 30 to 50 feet high, with remarkable willow-like leaves, which are 3 to 4 inches long, linear lanceolate, narrowed to both ends, smooth, and light green; the acorn globular with a saucer-shaped cup. This species grows in sandy low woods, ranging from Long island and New Jersey to Kentucky and southward. Its timber is of small value, from the coarseness of its grain and the openness of the pores. The shingle or laurel oak (*Q. imbricaria*, Mx.) is a tree 30 to 50 feet high, growing upon barrens and woodlands in New Jersey to Wisconsin and southward. Its wood is used in the manufacture of shingles, which gives the name to the species.—The Mexican species are said to be very numerous, and to form highly ornamental trees. Forests of the sharp-leaved oak (*Q. acutifolia*, Willd.) occur on the road from Acapulco to Mexico. It is one of the largest species of New Spain, and has a dense head of innumerable branches. The leaves, 5 to 6 inches long and 1 to 2 inches wide, have longish footstalks, are lobed at base, but taper to a very acute point, with coarse pointed teeth, smooth above, covered beneath with a brown woolly tomentum; the acorns are scarcely bigger than peas, and

the cups nearly cover the nuts. It is remarkable for beauty and singularity of foliage, as well as for grandeur and nobleness of general aspect. The ironwood oak (*Q. sideroxyloides*, Humboldt and Bonpland) is a lofty tree, a native of the temperate regions of Mexico at an elevation of 8,600 feet. Its wood is very valuable, hard and compact, takes a fine polish, and endures permanently when immersed in water. The blue-leaved oak (*Q. glaucescens*, H. and B.) forms forests at an elevation of more than 2,800 feet above the sea, in the warm parts of Mexico. Its wood is of great value, and employed for making charcoal. The Mexican oak (*Q. Mexicana*, H. and B.) is a very common and small tree, with white wood, much sought for the same purpose as the last. The laurel oak (*Q. laurina*, H. and B.) is a tall tree, with long, leathery leaves, oval-lanceolate, sharply acuminate, quite glabrous; it is a native of the temperate regions; its wood is very hard and in great esteem. Mr. Loudon, in his *Arboretum Britannicum*, vol. iii., gives 86 species with descriptions, as taken from the best authorities on this branch of the subject.—The Californian species of oaks have been examined by Prof. Torrey, and his descriptions can be found in the various reports of the United States exploring expeditions. Some of these had been previously noticed by the late Prof. Nuttall. Of these, the western oak (*Q. Garryana*, Hooker) is a tree 90 to 100 feet high, and its branches are proportionate to its altitude of stem; its wood is of remarkable whiteness, hard and fine-grained, and well suited to every kind of construction for which the white oak is employed, and to which natural section of the oaks it indeed belongs. Its acorns are sweet and agreeable, so much so that they are gathered and stored by the aborigines for food. This species had been found by Nuttall at the Dalles above the falls of the Columbia, and at Santa Rosa in California by other collectors. The holly-leaved oak (*Q. aquifolia*, Nee) is abundantly dispersed over the plain on which Santa Barbara is situated, forming a conspicuous feature in this portion of the western world. It is a tree about 40 or 50 feet high, with leaves which are evergreen and nearly as prickly as those of the holly; its wood is hard, brittle, and reddish, and is used chiefly for fuel. The dense-flowered oak (*Q. densiflora*, Hooker) is a remarkable tree, with entire evergreen leaves of lanceolate outline and pennate nerves, which so much resembles the chestnut even in the nut of the acorn, that the cup seems to be the only distinguishing character. It is a native of Upper California. The *Q. Hindsii* of Benthham is a tall species having a trunk of 3 feet diameter, and common in the valley of the Sacramento; and Emory's oak (*Q. Emoryi*, Torrey), a small-leaved species, is found at San Francisco mountain and the Aztec pass of New Mexico. For further references to these and to other Californian species, see "Reports on the Pacific Railroad Route," &c., senate

document of 83d congress, 1856, vol. iv., p. 188 *et seq.*—Some remarkably singular forms of North American oaks have been known to botanists. The Bartram oak (*Q. heterophylla*, Mx.), which was detected in a field belonging to Mr. Bartram's farm, and there only, but is now extinct, is considered by Prof. Gray as possibly a hybrid between *Q. phellos* and *Q. tinctoria*; and Lea's oak (*Q. Leana*, Nuttall), of which single trees occurred to the late Mr. T. G. Lea near Cincinnati, after whom it was named, and near Augusta, Ill., is thought by the same author to be a hybrid between *Q. imbricaria* and *Q. tinctoria*, or possibly *Q. nigra*. Admitting the probability of these instances being in reality hybrids occurring from fortuitous self-crossing or hybridization, which the rareness of their occurrence seems to warrant, it is a little remarkable that other instances have not been known in districts of country where several distinct species grow together in the same range of forest, or under cultivation by artificial planting.—The value of the oak is too well known for much detail here; and all the superior excellence of the timber of species natural to one region of the globe can be found in other species occurring in regions wide apart and diversely situated. The astringent properties of the leaves of *Q. falcata* cause them to be employed externally in cases of gangrene. This astringency is found in different degrees in all the oaks, and they have been used medicinally as febrifuges, tonics, and stomachics. Gallic and quercitannic acids have the power of guarding animal and vegetable fibres from decay; these are present in the bark of the oaks, and hence their value to the tanner. The acorns of many species afford valuable food not only for animals but for man.

OAKLAND, a S. E. co. of Mich., drained by branches of Clinton and Huron rivers and other streams; area, 900 sq. m.; pop. in 1860, 88,274. The surface is undulating, and in the N. hilly, and the soil is generally fertile and well cultivated. About 50 small lakes are scattered over the surface. The productions in 1850 were 586,346 bushels of wheat, 488,818 of Indian corn, 272,882 of oats, 205,527 of potatoes, 53,206 tons of hay, and 293,981 lbs. of wool. There were 28 grist mills, 13 saw mills, 12 iron foundries, 83 churches, and 10,457 pupils attending public schools. The Detroit and Milwaukee railroad passes through the capital, Pontiac.

OAKUM, the threads of hempen ropes picked to pieces, to be used when mixed with pitch for calking the seams of vessels. Until recently old men, women, and children were employed to pick oakum; but this is now chiefly done by machinery. The rope or junk is old rigging and cables bought up for this purpose. It is first cut by a powerful knife into short lengths, and these are thoroughly steamed to dissolve out the tar. The strands being then pulled apart, they are spread in the sun to dry.

After this they are torn in pieces and cleaned of dust in carding machines, a succession of which are used, until the oakum is obtained in clean light fibres. Saffron is often employed to give it a fine yellowish color. It is packed in bales for sale, and when used by the calker is rolled by the hand into "slivers," preparatory to driving it into the seams. Various unsuccessful attempts have been made to twist it into slivers by machinery.

OASIS, a name given by the ancients to the fertile spots found in the Libyan desert, and now become a general term for those situated in any desert. It is derived from the Coptic word *ouah*, a resting place, because there the caravans halted in their journeys between eastern and western Africa. Anciently they were supposed to be islands, rising up from an ocean of sand, although, on the contrary, they are depressions in the midst of a surrounding table-land resting on a bed of limestone, the precipitous sides of which encircle the hollow plain. In the centre of this valley is a stratum of sand and clay, which retains the water flowing into it from the surrounding cliffs. Here upon the cultivated portion grow palms, dates, and various kinds of fruits, beside rice, barley, wheat, and millet. These oases were never permanently occupied until after the conquest of Egypt by the Persians. Under the Ptolemies and the Cæsars they were occupied by the Greeks and the Romans; later they were used as places of refuge from persecution by the Christians, and subsequently by heretics. In the Sahara desert 32 of these oases are enumerated, of which 20 are inhabited. The most celebrated are the following, which are situated in the Libyan desert: 1. Ammonium, the modern El-Siwah, the most remote from the Nile, in lat. 29° N., long. 26° E., is the richest in historic associations. Here are the ruins of the temple of Ammon, and the supposed "Fountain of the Sun," whose waters were warm in the morning and evening and cold at mid-day, which excited the wonder of Herodotus. This oasis is 6 m. in length and 8 in breadth, and is remarkable for the productiveness of the soil, which is strongly impregnated with salt. It has now several towns, the principal of which is Kibir, and its inhabitants are subjects of Egypt. 2. Oasis Minor, the modern El-Bahryeh, is situated S. E. of El-Siwah in lat. 28° 30' N. It contains temples and tombs belonging to the era of the Ptolemies. It was also under the government of the Romans, and was then distinguished for its wheat; but now it produces principally fruits, such as dates, olives, and pomegranates. 3. Oasis Trinytheos, the modern El-Dakhleh, is situated in lat. 28° N., W. of the ancient city of Hermopolis Magna. No traces are to be found here of ancient architectural monuments of the Persians, Egyptians, or Greeks, the earliest being those of the Romans. Here have been discovered some Artesian wells; and as these were unknown to the nations just men-

tioned, the secret of their construction was probably brought from the East some time before A. D. 400. 4. Oasis Magna, the modern El-Khargeh, is situated about 90 m. W. of the Nile, with which stream it is parallel. It is 80 m. in length and from 8 to 10 in breadth, stretching from lat. 25° to 26° 6' N. It is sometimes called the oasis of Thebes, its centre being nearly opposite that city; by Josephus it is denominated "the Oasis," and by Herodotus "the city Oasis," and the "island of the blessed." It was under the dominion of the Persians, but its ruins generally belong to a later era. It had a temple 468 feet long, dedicated to Amun-ra, and after the Christian era abounded in churches and monasteries. Hither Nestorius is supposed to have been banished in A. D. 481. This oasis derives its modern name from that of its principal city.—Beside these, there are in the Libyan desert several other oases of considerable importance, and by some such large tracts of land as Fezzan are included under this term. The attractions of these oases are comparative rather than absolute. Many contain stagnant lakes, from which feverish exhalations arise, giving to the inhabitants a yellow complexion, and rendering the localities unfit to be visited during summer or autumn.

OAT, the common name of a genus of grasses having spikelets with 2 or many flowers in a loose and nodding panicle, with glumes containing 2 or more florets, the lower palea furnished with distinct lateral nervures, 2-pointed, with a bent or twisted awn, the stamens 8, and the ovary hairy at top. There are several species of oats; but the one most known and cultivated is the common oat (*avena sativa*, Linn.), having a spreading equal-sided panicle, the glumes mostly 2-flowered, longer than the florets, the uppermost 9-nerved, the florets smooth and 2-toothed at their apex. The native country of the common oat is a matter of conjecture, but probably it is Mesopotamia. In countries where other grain cannot readily grow the common oat becomes a valuable agricultural crop. It is accordingly raised for a bread corn in Ireland, Scotland, Norway, and Sweden. To render this crop profitable, attention must be paid to a careful preparation of the ground; in Scotland and Friesland the land is well cultivated, and the best oats thereby secured. The climate of Scotland is said to be peculiarly suited to the profitable raising of oats, which will there flourish when wheat and even barley languish. The grains or fruit of the oat consist of the skin or husk (which is removed by machinery) and the seeds, which when coarsely ground form oatmeal. Under proper cultivation the proportion of meal and of bran has been known to be as high as 78 per cent. of meal and 22 of husk. For food the meal is often simply stirred into boiling water with a little salt, until it becomes of the consistency of hasty pudding; it is then called porridge or stirabout, and when eaten with milk or molasses makes a wholesome and palatable food.

Oat cakes are made by mixing the meal with water and kneading it into a dough, which is baked on iron plates, producing a cake palatable to those accustomed to such a diet. Oat bread is stated by Sir Humphry Davy to furnish a great amount of nourishment, and to be preferred by miners to other kinds. The coarser meal, also, browned in a hot oven, is used in broths and pottages in Germany. Grits or groats are the seeds deprived of the husks, and these when prepared with water form water gruel, the thickness or thinness of the preparation depending upon the amount of nutriment required in the particular case. The chaff or husks being steeped in water for a few days and then drained off, the liquid when boiled stiffens into a dish called in Scotland sowens, of a slightly acid taste and of cooling property, and when mixed with milk forming a common food for supper among the peasantry. Enclosed in bags, the chaff also makes excellent and cheap beds. The unhusked grain is fed extensively to horses, and sometimes the oats are given in the heads and straw, where the animals are not expected to do very hard work. In the United States the common oat is extensively cultivated, but chiefly for the food of horses.—The naked oat (*A. nuda*, Linn.) has its grain loose in the husk; although occurring wild in many parts of Europe, it has been considered to be merely a degeneration of the common oat. In Austria, where it is common, it is cultivated for its grain, which is however small and not much esteemed, though some raise it as a superior sort for making oatmeal intended to be employed in diet for the sick. There are some other sorts regarded as distinct species, but which probably are only varieties rendered permanent by climatic differences.—The walking or animated oat of the gardeners is the *A. sterilis* of the botanists, from southern Europe, the seeds of which are enclosed in stiff, hairy husks, having each a long and remarkably hygrometric awn; this when dry is twisted closely upon itself, but when moistened by dew or rain it slowly uncoils, causing the seeds to sprawl about upon the ground. When two of these grains grow together, the awns thus united, the shape of the seed and hairiness of the glume represent some insect, and the motion, which is purely mechanical, seems to be of an animated and voluntary kind. This species is sometimes cultivated as a curiosity, and the seeds may be purchased at the seed stores of American florists.

OATES, THOMAS, the contriver of the "popish plot," born in England about 1620, died in 1705. He was the son of a ribbon weaver who had been an Anabaptist preacher under Cromwell, and became an orthodox clergyman under Charles II. He was educated at Cambridge, took orders, became chaplain to the duke of Norfolk, and held several curacies, but lost all his employments by his misconduct, and especially in consequence of two malicious prosecutions in which he appeared guilty of

perjury. He next obtained a chaplaincy in the navy, but was dismissed from it in disgrace, and seems then to have concocted with Dr. Tonge (Teonge, or Tongue), a clergyman of the established church, a weak and credulous man who was constantly haunted with visions of plots and conspiracies, the plan of qualifying himself for the position of informer against the Roman Catholics, of whom there was at that time a strong feeling of distrust in consequence of the open preference of the duke of York for the old religion, and the suspected tendency of the king (Charles II.) toward the same belief. In 1677 he accordingly professed himself a Catholic, and entered successively the colleges of English Jesuits at Valladolid and St. Omer, from both of which he was ignominiously expelled after a short trial. Returning to England in June, 1678, he caused a written narrative of a conspiracy of the Jesuits to murder the king and subvert the Protestant religion to be drawn up and laid before the king by Tonge. Charles perceived the imposture and paid no regard to it. Stimulated to fresh inventions by this cold treatment, Oates enlarged his fiction, and in September made a deposition before Sir Edmond Godfrey, a justice of the peace. He added to his story at various times, and the substance of it finally was that the pope had intrusted the government of England to the Jesuits, who had already issued commissions to prominent Catholics for all the high offices of state; that bishops had been appointed at Rome for all the English sees; that the Jesuits were the authors of the great fire of 1666, and that they were then plotting to burn all the shipping in the Thames. At a given signal the Catholics were to rise and massacre all the Protestants in the kingdom. The king was to be assassinated, and £15,000 had been offered to Wakeman, the queen's physician, to poison him in his medicine, the queen being privy to the plot. The names of the parties implicated were given, among whom were nearly all the principal Catholic gentlemen of the kingdom. A warrant for seizing persons and papers was obtained. The papers of the provincial of the Jesuits were examined, and nothing suspicious was found in them; but among those of Edward Coleman, secretary to the duchess of York, were some passages expressing the hope or expectation of a speedy reestablishment of the Catholic religion. This was unhesitatingly construed as evidence of the plot. Some color was lent to the suspicion by the death within a month, whether by suicide or murder was never ascertained, of the magistrate before whom Oates's deposition had been taken. The body was carried to the grave with every demonstration of popular excitement. Sir Edmond Godfrey was styled a martyr to the Protestant cause. "The capital and the whole nation," says Macaulay, "went mad with hatred and fear. The penal laws, which had begun to lose something of their edge, were

sharpened anew. Everywhere justices were busied in searching houses and seizing papers. All the gaols were filled with papists. London had the aspect of a city in a state of siege. The train bands were under arms all night. Preparations were made for barricading the great thoroughfares. Patrols marched up and down the streets. Cannon were planted round Whitehall. No citizen thought himself safe unless he carried under his coat a small flail loaded with lead to brain the popish assassins." Oates became a popular hero. Almost in a moment he was raised from beggary to wealth. "He walked about," says Roger North, "with his guards assigned for fear of the papists murdering him. He had lodgings in Whitehall, and £1,200 per annum pension. . . . He put on an episcopal garb except the lawn sleeves—silk gown and cassock, great hat, satin hat band and rose, long scarf—and was called or most blasphemously called himself the saviour of the nation. Whoever he pointed at was taken up and committed." His example was imitated by a multitude of the most despicable wretches of London, one of whom swore that he had been offered canonization and £500 to murder the king. Shaftesbury and Buckingham and the party opposed to the court were not long in using the plot as a political engine, if indeed they were not, as some suppose, the originators of it. "Shaftesbury," says North, "was the dry nurse, and took the charge of leading the monstrous birth till it could crawl alone." It has also been conjectured that the court got up the plot for its own purposes, and that the opposition took it out of the court's hands for its own purposes also. It is difficult at all events to acquit Charles of the charge of assenting to prosecutions which he knew to be groundless, in order to rid himself of the suspicion of leaning toward the Roman Catholic religion. The trials of the Roman Catholics began in Nov. 1678. The chief justice Scroggs displayed the most ferocious anxiety to convict. Juries were equally vindictive. The populace applauded Oates and his colleagues, pelted the witnesses for the defence, and shouted with delight whenever a verdict of guilty was pronounced. Stayley, a Catholic banker, Coleman, and 8 Jesuits named Grove, Pickering, and Ireland, were the first victims. Upon the pretended confession of one Bedloe, a noted swindler, three persons were next convicted of the murder of Godfrey. Five peers were sent to the tower under impeachment. For two years conviction followed accusation almost as a matter of course. No lie was too gross to be believed against the Catholics, no evidence was suffered to weigh in their favor. At last the utter improbability of Oates's story, his frequent self-contradictions, and his notoriously bad character began to be considered. His statements were first publicly questioned on the trial of Wakeman, the queen's physician. Wakeman was acquitted, and when Lord Stafford was executed for complicity in the

plot in Dec. 1680, the multitude loudly expressed a belief in his innocence. Toward the close of Charles's reign the duke of York instituted a civil suit against Oates for defamatory words, a jury gave damages in the amount of £100,000, and the impostor was thrown into prison as a debtor. About the same time the grand jury of Middlesex found two bills against him for perjury, and shortly after the accession of James II. he was convicted on both indictments (1685), and sentenced to pay a fine of 2,000 marks, to be stripped of his clerical habit, pilloried in Palace yard, led around Westminster hall with an inscription over his head, pilloried again in front of the royal exchange, whipped from Aldgate to Newgate, and after an interval of two days whipped from Newgate to Tyburn, imprisoned for life, and 5 times every year pilloried in different parts of the kingdom. The judges never supposed he would survive the punishment. In the pillory in Palace yard he was nearly killed; before the royal exchange his partisans raised a riot and attempted to rescue him. On the next day he received the first scourging, the hangman laying on the lash with terrible severity. Oates swooned several times, and his shrieks were frightful. At the second whipping he was unable to stand, and had to be drawn on a sledge. A by-stander counted 1,700 blows of the whip. He escaped with life, however, and remained a prisoner until the accession of William of Orange, who annulled his sentence, released him, and afterward gave him a pension of £5 a week. The personal appearance of Oates is described as extremely revolting. He figures in Sir Walter Scott's "Peveril of the Peak."

OATH, a solemn act by which one calls God to witness the truth of an affirmation or the sincerity of a promise, and imprecates divine vengeance on his falsehood or on the violation of his faith. In all times and among all nations men have agreed in reposing singular trust in declarations made under such a sanction. In primitive and in all purer states of society, solemn oaths, it would seem, have been universally taken in the name of superior beings. Among the Jews, the Greeks, and the Romans, there came to be a familiar distinction between their greater and their lesser oaths. The same is probably true of other nations. These less solemn forms of adjuration include oaths by sacred objects, or by things peculiarly dear to those who employed them. Thus, the Jews swore by Jerusalem and by the temple; the Greeks as well as the Romans by the souls of the dead, by the ashes of their fathers, by their life or the lives of their friends, by their heads, and their right hands. These forms had their origin partly too, perhaps, in the custom of touching, during the recital of the usual formula, some object sacred to or suggestive of the divinity invoked; so that, as during the administration of the oath the swearer laid his hand upon a crucifix as a sacred symbol, or

touched the altar while he swore by the god in whose honor it was raised, he came at last to swear not by the divinity, but by the altar or the "good rood" itself. But when these less impressive oaths came into common use, as they did remarkably among the Jews and the Greeks, perjury seems to have become equally common. With good reason then may it be asserted, and it is the theory of our law, that the confidence which men repose in oaths rests not in the mere ceremony of naming reverently some consecrated object, or even of calling God to witness the affirmation, but in the solemn imprecation of divine judgment upon perjury. When the Jew took his most solemn oath, he laid his hand upon the book of the law and swore by the God of Israel, by him who is merciful and gracious; but the ordinary oaths were by heaven, the altar, or the temple. The ancient Indians swore by a stream which flowed from a sacred fountain. According to Grecian mythology, the gods swore by the Styx, and made a libation of its waters; and if any immortal swore falsely, he was deprived of nectar and forfeited his divinity for 100 years. In early times the Grecian men swore by Jupiter, and the women by Juno and her chaste bed. Later each state invoked its tutelary gods or heroes. The Thebans called on Hercules, the Lacedæmonians on the Dioscuri, and the Corinthians on Neptune. The rite which usually accompanied the oath consisted simply in placing the hand upon the altar. Among the early Greeks, as we learn from Homer, the parties mingled wine in token of their concord, and then poured it out upon the ground, calling upon the gods to scatter the brains of him who first violated his faith. The form was often suggested by the office or character of the person swearing. Soothsayers swore by Apollo, merchants by Mercury, and husbandmen by Ceres. Achilles swears by his sceptre, Telemachus by his father's sorrows, Pythagoras by the air he breathed and the water he drank, Socrates by a dog and a plane tree, and Demosthenes by the heroes of Marathon. Solon commanded the invocation of three of the greater gods. Public oaths were then administered in Athens in the names of Jupiter, Neptune, and Minerva. Purgatory oaths were taken in the names of Jupiter, Neptune, and Themis, and judges swore by Jupiter, Ceres, and Helios. Numa commanded the Romans to swear by Fides. In an early and solemn form of adjuration, the swearer took in his right hand a pebble and threw it away with the words: "If knowingly I speak falsely, may Diospiter cast me away as I cast away this stone." In the most flourishing period of the state it was common to swear by the majesty or by the life or welfare of the emperor. After the murder of Cæsar, the senate decreed that the citizens should swear by his genius.—The ancient Scandinavians and Germans swore by their gods. Among both nations it was customary, while repeating the oath, to rest the

hand on some special object. This was sometimes significant of the god addressed, and sometimes reminded the swearer of the punishment which followed perjury. The Scandinavians touched a bloody ring held by the priest. The Germans swore by their swords or beards. In early Christian times oaths were administered in chapels and other holy places, at the altars, which for the occasion were rendered more sacred by placing upon them holy relics. In modern times the Germans have sworn by God, and sometimes also by the holy evangel. Roman Catholics add an invocation of the saints. The party swearing raises his right hand, with the thumb and first two fingers extended, and the two remaining fingers closed upon the palm. The former typify the trine, omniscient, and all-righteous God; while the latter remind the witness, it is said, of the soul and the body which the swearer will have forfeited if he forswear himself. Women and ecclesiastics lay the hand upon the breast; the former because in old times, whence the custom comes, they were suspended from their necks a copy of the Gospels; and the latter, if we accept the suggestion of Heineccius, because they were supposed to have the word of God written on their hearts.—It is sometimes laid down that in the definition of an oath two things are to be distinguished: 1, the invocation by which God is called to witness the truth of what is sworn; and 2, the imprecation by which God is called on to punish falsehood. Many writers of authority have indeed defined an oath without any mention of imprecation. Thus Cicero speaks of an oath as an affirmation under the sanction of religion; and more explicitly Voet, in his "Commentaries upon the Pandects," writes that it is a religious affirmation of the truth, or an invocation of the name of God in witness of the truth. A Spanish jurist, Perez, defines an oath as an affirmation on any subject by the name of God and some sacred thing; and the author of Fleta as the affirmation or negation of some point confirmed by the attestation of a holy thing. Coke uses similar language to these. But so far as the legal definition and conception of an oath are concerned, the omission of this element of imprecation must not be made, for neither in our own nor in the French or German law would any religious affirmation be regarded, if alone, as a sufficient oath. Nor, from a review of the history of oaths, does it seem generally to have been thought that the most solemn obligations were assumed by mere invocation alone. The sanction and force of an oath lie peculiarly in the imprecation of divine vengeance upon perjury. This element is certainly held essential by our law; and in this respect it is supported by the highest authorities—the Pandects for example, Grotius, Pufendorf, Rutherford, and Heineccius. In the language then of Phillips, an eminent text writer upon evidence, a witness, in taking an oath, must be understood to make a formal and solemn appeal to the

Supreme Being for the truth or the evidence which he is about to give; and further, to imprecate the divine vengeance upon his head if what he shall say be false. Atheists therefore, as they deny the existence of a Supreme Being, and such infidels as profess a religion which does not bind them to speak the truth, could not, by the common law, be witnesses. It was laid down in the leading and interesting case of *Omichund vs. Barker*, that the competency of a witness in regard to his religious opinions should be tested by the questions whether he believed in a God, in the obligation of an oath, and in a future state of rewards and punishments. But it is not now required that the witness believe in future punishment. Generally a disbelief in a future state goes only to affect the credibility of the witness; but he will be admitted to testify under oath if only he believes in the existence of a God who will punish crime, it matters not whether in this life or in another. If, on being questioned, the witness reply that the usual form of the oath will be binding on his conscience, it would be irrelevant and unnecessary to examine him further as to his belief. What this may be is immaterial; for if he takes the oath, he is understood to assume its religious obligations, and subject himself to the legal penalties which are inflicted on perjury if he speak falsely. The English statute 17 and 18 Victoria, c. 25, permitted those who from conscientious motives should be unwilling to take an oath, to make instead their solemn affirmation. The same indulgence is granted by statutes in the United States; and in some of the states there are even further relaxations of the ancient rules. (See EVIDENCE.) The form of administering the oath has nothing to do with the oath itself. That form is in every case the best which most forcibly impresses on the swearer the obligation of the oath, or in other words is most binding on his conscience. Jews are sworn therefore on the Pentateuch, and with covered head. Mohammedans are sworn upon the Koran. A Chinese has been sworn with the ceremony of breaking a china saucer; and the deposition of a Hindoo has been received who touched with his hand the foot of a Brahmin. Even one who professes Christianity may be sworn on the Old Testament, if that form alone is binding on him.—Of the various kinds of oaths, the promissory, assertory, decisory, and *calumnia causa* are most frequently met with. Promissory oaths refer to future acts, like those taken by public officers for the guaranty of their faithful performance of official duties; or they attend the promise to execute some contract or undertaking. Assertory or affirmative oaths establish the certainty of a present or past fact. To this class belong the various forms of decisory oaths; for example, the voluntary, when, as in the civil law, one asserts the justice of his claim; or the necessary, when the judge calls in one of the contesting parties to swear to a

matter doubtful to him, in order to assist his determination of the cause. But the decisory oath by excellence is perhaps that in the civil law, which one party offers to the other, for the decision of the matter in dispute; that is to say, a party whose proof is defective may tender an oath to his adversary, offering to submit to whatever he shall thus declare touching the matter. If the fact in question lie particularly within the knowledge of the latter, he must swear, or the plaintiff's general allegations will be regarded as proved. If the fact lie within the knowledge of both parties, he to whose oath it was referred may elect either to swear or to refer the matter back to the party who first tendered the oath. If he refuse to do either, the fact alleged is held to be confessed and proved. In the Roman system, when an action was brought, either party must, at the other's request, take an oath that he did not maintain or defend the cause *calumnias causa*; that is, for the mere sake of harassing his opponent. If the party challenged took the oath, the other could bring no action against him for reckless litigation. Before Justinian this procedure was optional, but he made it a necessary preliminary to bringing or defending any action.

OAXACA. See OAJACA.

OBADIAH (Heb., servant of the Lord), one of the minor prophets. We know nothing of him except his name; his native country, the place where and the time when he prophesied, are entirely uncertain, as neither his own prophecy nor other contemporaneous writings contain any information respecting them. It is, however, generally inferred from the tenor of his prophecy that he was an eye-witness of the destruction of Jerusalem by Nebuchadnezzar. The prophecy of Obadiah is the shortest book of the Old Testament, containing only one chapter, of 21 verses. It is directed against the Edomites, who maliciously assisted in the capture and destruction of the holy city. The prophet announces to them the fall of their capital Edom, and the approach of divine aid for Israel.

OBE. See OBI.

OBELISK (Gr. *obeliskos*, diminutive of *obelos*, a sharpened thing, a skewer or spit), a lofty monolithic, quadrangular shaft, tapering gradually from the base to the summit, which terminates in a pointed, four-sided pyramid. The obelisks are among the most simple and striking of the architectural monuments of Egypt, to which country they are peculiar, and are connected by tradition with its earliest public works. The oldest of which we have any knowledge is that now standing at Heliopolis, inscribed with the name of Osirtasen I., of the 12th dynasty, who flourished between 2000 and 1860 B. C.; and between that era and the Persian conquest, 525 B. C., all those of Egyptian origin known to be in existence were erected. None occur of later date than the latter event. Many fanciful and in-

genious theories have been advanced to explain their purpose and origin, but without clearing the mystery attaching to the subject. They were long regarded as connected with the worship of the sun, and some etymologists derive the name from a Hebrew word supposed to signify a serpent sacred to the sun. Others again have attempted to prove that they were employed as sun dials, or as monumental columns in honor of the great luminary. The term itself throws no light upon the subject, and the ludicrous association of its original signification, a spit or stout needle, with the colossal shafts to which it is applied, is suggestive of the caustic humor of the Alexandrian Greeks. In the opinion of recent Egyptologists the obelisks were monumental structures, partly religious, partly historical in character, and to some extent ornamental, placed at the entrances of palaces and temples to indicate by the inscriptions carved upon them the purposes to which such edifices were to be applied, the divinity to which they were dedicated, the name and regnal year of the king who erected them, and other facts of sufficient public importance to be thus recorded. As architectural accessories they relieved the monotony of the numerous horizontal lines occurring in buildings constructed by the Egyptians. They generally stood in pairs, the smaller ones being either of sandstone or granite, while the larger were almost invariably of the rose-colored granite of Syene in southern Egypt, which is susceptible of a fine polish. The shaft was usually from 8 to 10 times higher than the width of its base, and $\frac{1}{2}$ narrower at the top than at the base, which rested on a quadrangular pedestal, several feet broader than the obelisk. The base was seldom perfectly square, two of the sides being somewhat broader than the other two; and for the purpose of obviating the concave appearance which under certain conditions of sunlight a plane surface would present, the faces of obelisks, particularly of those which are opposite to each other, exhibit a slight convexity about their centres—"one of the many proofs," says Sir Gardner Wilkinson, "of their (the Egyptians') attentive observation of the phenomena of nature." The apex or pyramidion was also more pointed in some obelisks than in others, and appears occasionally to have been sheathed with metal. Wilkinson mentions one near Biggig which has a rounded apex. They varied in height from 20 to somewhat over 100 feet, and the largest weighed from 400 to 500 tons. The process of hewing these colossal blocks from the quarries and transporting them, in some instances 800 m., to the places where they were to be erected, must be reckoned among the most wonderful achievements of the ancient Egyptians. The obelisk appears to have been rough hewn on 8 of its sides while adhering by the fourth to the quarry, from which it was finally separated by a number of meat wedges struck at the same instant along its whole length. Sometimes the wedges were of wood,

which, being driven into holes previously cut for them and then saturated with water, split the stone by their expansion; although, according to Wilkinson, "such a method could only be adopted when the wedges were in a horizontal position, upon the upper surface of the stone; but those put into the sides were impelled by the hammer only." Some doubt has been thrown upon this theory of the method of excavation from the fact that the granite of Syene at the present day appears of too hard a texture to admit of being thus quarried. From an inspection of some of these quarries it would seem that the block, when separated from the rock, was lifted directly from the hollow in which it had been cut, although, according to Pliny, it was sometimes lowered down an inclined plane or platform to a raft, formed by lashing two flat-bottomed boats together, and which had been brought up to the very edge of the quarry either at the time of inundation or by means of a canal dug from the Nile. This may have been the case with small obelisks, but the large ones were transported altogether by land on sledges and rollers, according to the method represented in the ancient picture which forms the frontispiece to the 2d volume of Sir Gardner Wilkinson's "Ancient Egyptians." Evidently the transportation of obelisks from Syene to Heliopolis in lower Egypt must have occupied several years. The erection of the obelisk when arrived at its destination was accomplished, according to Diodorus, by means of mounds or inclined planes of earth. Previous to this, it was carefully polished, and the necessary figures and hieroglyphics were inscribed by the sculptor. Some, however, are without inscriptions of any kind.—The number of monuments of this species, probably at one time considerable in Egypt, has been greatly diminished by the violence of wars, neglect, and various physical causes. Many of them are no longer standing, but lie upon the adjoining ground, in some instances broken and mutilated. The Persian conqueror Cambyzes, who is said to have overthrown a number when he sacked Thebes and other cities, was so struck by the magnificence of one erected in the former place by Rhamses, and to which that monarch had ordered his own son to be bound in order that its erection and proper adjustment might be insured, that he countermanded the order given for its destruction. Under the Ptolemaean kings many obelisks were removed to Alexandria; and the Romans upon becoming masters of Egypt conveyed several of great size by sea to Rome as memorials of their triumphs. Eleven of these are still standing there, although not in the positions where they were originally placed, the greater part having been overturned and in some instances broken during the decline of the empire and the successive plunderings of the city by barbarian hordes. Sixtus V. first conceived the idea of reerecting or restoring these ancient monuments of art, and in 1586 the

obelisk of the Vatican was placed on its present pedestal by the architect Domenico Fontana, whose plan had been selected out of 500 offered to the pope. This obelisk, which, exclusive of its base and the ornaments on the apex, has a height of 82 ft. 2 in., was brought from Heliopolis by the emperor Caligula, in a ship described by Pliny as the largest which had ever navigated the sea. The same pope, with the assistance of Fontana, subsequently erected the obelisks of S. Maria Maggiore, the Lateran, and the Piazza del Popolo, each of which was found lying on the ground, broken into several pieces and encumbered with rubbish. That of the Lateran, the largest now known, was brought from Heliopolis to Alexandria by Constantine the Great, and was removed to Rome by his son Constantius, who placed it on the spina of the Circus Maximus. Notwithstanding a portion of the lower part was cut off by Fontana, in order to adapt the fragments, it measures 105 ft. 7 in. without the ornaments and pedestal, and is estimated to weigh 450 tons. That in the Piazza del Popolo, measuring 78 ft., was brought from Heliopolis by Augustus and placed in the Circus Maximus. This and the two latter are covered with hieroglyphics, but the obelisk of S. Maria Maggiore, the smallest of the three, is destitute of them. The other obelisks in Rome are: that of the Piazza Navona, 51 ft. in height, found in the circus of Romulus, and erected by Bernini in its present position in 1651, during the pontificate of Innocent X.; that of S. Maria sopra Minerva, 89 ft., erected in 1687 by Bernini in the pontificate of Alexander VII.; that of the Pantheon, 17 ft., erected in 1711 by Clement XI.; those of Monte Cavallo, 45 ft., Trinita de' Monti, 44 ft., and Monte Citorio, 71 ft. 6 in., erected in 1786-'92 under the pontificate of Pius VI.; and that of Monte Pincio, 30 ft., erected in 1822. In all cases the dimensions of these are given without the bases or the tasteless additions in the shape of globes, stars, or rays, which the Romans placed on the apices under the impression that they were originally intended for sun dials. Several of those in modern Rome terminate in crosses. Obelisks were also transported to Constantinople before the severance of the empire, and others are to be found in Velletri, Benevento, Florence, Catania, and Arles, although not all of these are of Egyptian origin. That in the last named place, which was discovered in 1889 buried in the mud of the Rhone, and erected in its present position in 1675, is nearly 54 ft. in height.—The obelisks remaining on their ancient sites are comparatively few. Among the most famous are that at Heliopolis, already mentioned, 68 ft. 2 in. in height above the base, and which formerly, according to tradition, had a companion one; a very fine one at Luxor, 70 ft. 2 in. in height, erected by Rhamses II.; four at Karnak, the two largest, of which one is fallen, measuring 92 ft. in height by 8 at the base; and the two at Alexandria known as Cleopatra-

tra's needles. A companion obelisk to the one in Luxor was in 1838 transported to Paris, and in 1836 erected in the Place de la Concorde, where it now stands. Under the influence of the moist climate of Paris the granite has so rapidly disintegrated that it has become necessary to take plaster impressions of its hieroglyphics in order that they might not be entirely lost. Sir Gardner Wilkinson, who witnessed the removal of this shaft from its original position, discovered that it had been cracked previous to its erection and secured by two wooden dovetailed cramps. The Cleopatra's needles, which are about 70 ft. in height with a diameter at the base of 7 ft. 7 in., stood originally at Heliopolis, and were brought to Alexandria by one of the Cæsars.—One of them, which has been thrown down and lies close to its pedestal, was presented by Mehemet Ali to the British government, who at one time determined to transport it to England. But from its mutilated condition and the obliteration of many of the hieroglyphics, its value has become so greatly reduced, that it has been considered unworthy the expense of removal. The so called obelisk brought from Philæ to England by Mr. Banks measures 22 ft. 1 in., and is the largest Egyptian monument of the kind in Great Britain. Properly speaking, however, it is not an obelisk, but a stela. The British museum has 2 small ones brought by the French from Cairo.—Monuments of the obelisk form, not in all cases monolithic, have not been uncommon in modern times, that erected on Bunker hill being a well known example. Monolithic monuments nearly resembling Egyptian obelisks have been recently excavated among the Assyrian ruins of Nimroud. The British museum contains an interesting specimen, 6 ft. 6 in. high, 2 ft. wide at the bottom, and 1 ft. 6 in. at the top, which, instead of terminating in a pyramid, diminishes by 3 steps, the summit presenting a perfectly flat surface. It is profusely adorned with bass-reliefs and inscriptions, but is far inferior in design and execution to the Egyptian monoliths. The obelisk in Axum, Abyssinia, the survivor of 55 monuments of this kind once standing there, terminates in a rounded patera, and has been supposed to be of a date later by many centuries than the most recent Egyptian obelisks.

OBERFLAUCHT, a village of Würtemberg, in the district of Tuttlingen, noted for sepulchral remains discovered there in 1855, and supposed to date from the Carolingian period. The relics of many of the graves, upward of 60 of which have been opened, are preserved in the museum of the Nuremberg archaeological society. With the skeletons were found swords, lances, arrows, and well preserved bows of yew, 6 to 7 feet long. Among other relics were forms of wooden feet supposed to represent the mythological death-shoes (*Todenschuhe*).

OBERLIN, a village of Lorain co., Ohio, on the Cleveland and Toledo railroad, 84 m. S. W. from Cleveland; pop. in 1860, 2,132, exclusive

of students. It is noted principally as the seat of Oberlin college, founded in 1834 and named, after J. F. Oberlin. Its discipline combines manual labor with study, and by its rules males and females are admitted without regard to color. The institution is under the direction of the Evangelical Congregationalists, comprises several distinct departments, occupies 7 commodious buildings, and has 900 students. The village contains a large Congregational church, capable of holding 3,000 persons, and an Episcopal church.

OBERLIN, JEAN FRÉDÉRIC, a French philanthropist, born in Strasbourg, Aug. 31, 1740, died in Waldbach, in the Ban de la Roche, June 1, 1826. From a child he was remarkable for benevolence and courage. He was educated at the university of Strasbourg, and ordained, but did not immediately take a pastoral charge, remaining 7 years as a tutor in a physician's family. In 1767 he succeeded Stouber as pastor of the villages in the Ban de la Roche, Alsace. This district, lying in the Vosges mountains, contained about 9,000 acres of sterile, rocky soil, with no roads except difficult mule paths. The people were very poor, ignorant, and indolent; they had few agricultural implements and little knowledge of agriculture; their language was a barbarous *patois*, and very few of them could read even imperfectly. Oberlin spent 60 years among them, laboring for their social, intellectual, and moral improvement. By his example and influence, good roads, bridges, and comfortable dwellings were erected; admirable schools were established, in which all the children and many of the adults were taught; agriculture and horticulture were so greatly improved, that this barren and desolate region became like a garden, producing considerable quantities of vegetables for exportation, notwithstanding its dense population; the French language came to be spoken in as much purity as in the large cities of France; churches were erected; and in morality and religion the Ban de la Roche became a model for the rest of France. The infant school, the Sunday school, and the asylum for homeless and helpless children, were all measures originating with Oberlin; and though about the same time similar institutions were devised in other countries, there is abundant proof that his organizations were not borrowed from those of others. The training of female teachers for their work was also first attempted by him in his school of conductresses. (See "Memoirs of John Frederic Oberlin," by H. Ware, jr., Boston, 1845.)—JÉRÉMIE JACQUES, elder brother of the preceding, born in Strasbourg, Aug. 7, 1735, died there, Oct. 10, 1806. He was a graduate of the university of that city, and officiated for many years as professor in various branches of study, particularly of logic and metaphysics. He published several works relating to Roman archaeology and to the provincial dialects of Lorraine, and various other writings.

OBI, ~~Obz~~, or OB, a river of Siberia, formed, at about lat. $51^{\circ} 40' N.$, long. $85^{\circ} 20' E.$, by the junction of the Katunga and Biya, which rise in the Altai mountains. It pursues a very circuitous but generally N. W. course to lat. $60^{\circ} 40'$, where it is joined by the Irtysh from the S., whence the united stream runs nearly N. to Obdorsk, lat. $66^{\circ} 40'$, where it separates and flows E. into the gulf of Obi by 3 mouths after a course of about 2,000 m. Beside the Irtysh, which after receiving the Tobol is larger than the river into which it flows, the principal tributaries of the Obi are the Tom, Tchulim, and Vak. Fish are abundant in all these rivers. The gulf of Obi is an inlet from the sea of Kara, which lies between Nova Zembla and the mainland. It is of irregular form, extending between lat. $64^{\circ} 30'$ and $73^{\circ} N.$ and long. 68° and $77^{\circ} E.$

OBI, an African word signifying a species of sorcery or witchcraft common among the fetish-worshipping negro nations. In Africa the practice bears different names in different languages. In the British West Indies, where it formerly existed among the slaves to an extent that called for legislative interference, the name obi was universally used. The practisers of the art, who were always native Africans, were called obi men or obi women, and were held in great dread by the negroes, who consulted them as oracles, and applied to them for the cure of disorders, to obtain revenge for injuries, and to discover and punish thieves and other offenders. Their mode of operation was to prepare a magical fetich, which, being set up near the dwelling of the person to be bewitched, was supposed to produce the most direful effects upon his health and welfare. The law of Jamaica, enacted in 1760, which prohibited under severe penalties the practice of obi, enumerates among the materials used for fetiches or spells, blood, feathers, parrots' beaks, dogs' teeth, alligators' teeth, broken bottles, grave dirt, rum, and egg shells. Balls of earth or clay mixed with hair, rags, or feathers, and bound with twine, or in some cases blended with the upper section of the skulls of cats, or stuck round with cats' teeth and claws, or with human or dogs' teeth, and with glass beads, were also used. The negroes who became aware that "obi was set for them" generally soon fell ill from terror, and almost invariably died of a species of decline. It is probable, also, that poison was occasionally used to heighten the effects of the supposed enchantment. In 1760 the influence of the obi men produced a formidable insurrection among the slaves in Jamaica, and several of these sorcerers were hanged by the authorities.

OBION, a N. W. co. of Tenn., bordering on Ky., separated from Mo. by the Mississippi river, and intersected in the S. E. by the Obion river; area, about 700 sq. m.; pop. in 1850, 7,638, of whom 1,057 were slaves. Its surface is low toward the Mississippi, and elevated and undulating in the E., and the soil is fertile. The productions in 1850 were 445,420 bushels of

Indian corn, 9,413 of oats, 189,805 lbs. of tobacco, and 54,379 of butter. There were 10 grist mills, 2 saw mills, and 6 churches. The Mobile and Ohio railroad intersects the county. Capital, Troy.

OBJECTIVE AND SUBJECTIVE, in modern philosophical language, terms applied respectively to things in the mind and to things outside of the mind, to the internal and to the external element, in every act of thought. The subject is *id in quo*; the object, *id circa quod*; and all knowledge is but a relation between the subject in which it adheres, and the object about which it is conversant. The subjective exists merely in the thought of the individual, in the Ego; the objective exists in nature, in the Non-Ego. To analyze the contents of our thoughts, and distinguish what elements are contributed by the knowing subject and what by the object known, is one of the principal problems of philosophy. The distinction suggests the inquiry, which has been raised in every age of speculation, whether the objects of thought really exist at all apart from the mind, or, if they do, whether they are truly and adequately represented by the ideas which we have of them. Protagoras taught that we know nothing of external things in themselves, but judge them only by their relation to us, by the measure of our own faculties. Gorgias maintained that truth is inaccessible to the human mind, that there is a fatal chasm between thought and objective reality. Anesidemus and the new academy anticipated Hume by making the relation of cause and effect merely a law of our own intelligence, and denying its existence in the nature of things. Carneades argued against the stoics that we have no means of discovering whether our faculties are truthful or false, adequate or inadequate, or whether any thing in nature corresponds to our ideas. The distinction between the subjective and objective, thus familiar to Greek thought, was not, however, expressed by the corresponding terms *ὑποκειμενον* and *ἀντικείμενον*, the former of which meant substance and also the subject of a proposition. The Latins translated them *subiectum* and *objectum*, which the scholastic philosophers opposed to each other, but by giving them significations nearly the reverse of those which they bear now. They understood by the subject the unknown basis of phenomenal or manifested existence, the substance underlying the phenomena of objects. Subjective is thus used by Occam to denote that which exists independently of mind; objective, that which the mind feigns. The same meaning is preserved by Berkeley, who opposes the real or subjective to the phenomenal or objective nature of things. This explains the *realitas objectiva* of Descartes, which meant only existence in idea, or, in modern phraseology, subjective existence. Objective existence was expressed by formal or actual reality. Thus, according to Descartes, the sun exists objectively in our thought of it, formally in the heavens. But the term sub-

ject, in the sense of substance, was equally applicable to the internal and the external worlds; it could designate the unknown basis, the essential principle, of mental as well as material phenomena. Kant transferred it from outward nature, and appropriated it exclusively to the mind, and the result was an inversion of the meanings of objective and subjective. The distinction underlies the whole critical or transcendental philosophy, the different schools of which rest upon changes played upon this relation. According to Kant, the pure reason can affirm only the subjective existence of whatsoever objects of thought; time, space, cause, the soul, matter, and God appear only as simple forms of thought, without outward reality. The practical reason, however, dogmatically and unscientifically affirms that they also exist objectively. The system of Fichte recognizes only a single and absolute principle, the Ego, which is at once subject and object, its own observer and its own spectacle, which in developing itself creates the universe, nature, and man. It resembles the pure Kantian system, without the contradictions of the practical reason. While the idealism of Fichte thus derived the object from the subject, Schelling developed a system of transcendental identity, rising above both the terms to a superior principle in which they are united and blended. All opposition between them disappears; nature and the soul proceed alike from the absolute being, in whom their identity is manifested, and who in developing himself becomes the universe, nature, and man. The scheme is pantheistic; the human faculty of intuition comprehends the absolute by becoming absolute, and all thought is objective. The subjective idealism of Fichte and the objective idealism of Schelling gave place to the absolute idealism of Hegel, which recognizes only the logical processes of universal reason, and affirms being and thought to be identical.—The terms have been transferred from philosophy to literature and art, where they characterize respectively real and ideal qualities and tendencies.

OBOE. See HAUTOY.

OBOLUS, a small Greek coin, $\frac{1}{4}$ of a drachma, equal in value to about 2.6 cents. In the best times of Athens it was made of silver only, but later of bronze. It was the price of the passage over the river Styx, and the Greeks put an obolus into the mouth of the dead, for Charon, the ferryman.

OBRENOVITCH, a Servian family, three members of which, MILOSH (born about 1780, died Sept. 26, 1860) and his two sons, MILAN (born Oct. 12, 1819, died July 7, 1839) and MICHAEL (born Sept. 4, 1825), have held the princely dignity in their native country during the last 50 years. Milosh was the son of Tesho, a poor laborer of the village of Dobrinje, and together with his two brothers, Ivan and Yefrem, was for some years engaged in grazing, and subsequently entered the service of his uncle, Milan Obrenovitch. The latter having joined the

popular rising against the Janizaries early in the 19th century, in which he rose to the dignity of vayvode or commander, Milosh exchanged his farming implements for the sword, fought bravely in various engagements, and earned not only great renown among his warlike countrymen, but for some time also the favor of the chief revolutionary leader, Czerny or Kara George. During the war, Milosh married Lyubitza, by whom he became the father of four children, two of them daughters. On the outbreak of the Russian war against Turkey in 1809, Milosh again served with distinction; and when in 1810 his uncle, who was sent on a mission to the Russian camp, failed to return, he succeeded him, under the adopted name of Obrenovitch, in military command as well as in the possession of his estate. The disastrous period which followed the peace of Bucharest (1812), concluded between the czar and the sultan, offered Milosh still greater opportunities for displaying his patriotism and courage, one of his most renowned feats being the defense, for 17 days, of the village of Ravani in 1813; and when even Czerny George despaired of success and fled from the country, he alone persisted, obtained favorable terms from the Turks, and was by them appointed as *knez* with the mission of pacifying the country, which he accomplished (1814). The Moslems, however, soon committed new acts of violence; and on Palm Sunday, 1815, Milosh again gave the signal for insurrection. Though meeting with some defeats at the beginning of the new struggle, he soon after became victorious, and in 1816 conquered a favorable peace, which guaranteed national autonomy to the larger part of the Servian territory, but left the Turks in possession of Belgrade and other towns. The pasha of Belgrade attempted in vain to remove him by treacherous means; and in Nov. 1817, he was solemnly elected hospodar of Servia by an assembly of bishops and chiefs. Four months earlier Czerny George, who had secretly reentered the country which he had delivered, was treacherously sacrificed to the bloody vengeance of the Turks. Various conspiracies against Milosh, in 1820, 1824, and 1825, were suppressed with energy and cruelty, and he was not only acknowledged as hospodar by the national assembly (*skupstchina*) of Kraguyevatz in 1827, but after the new Russian war against Turkey and the peace of Adrianople (1829) was also confirmed by the Porte as hereditary prince of Servia, the limits of which were enlarged and finally fixed by a *hatti-sherif* in 1834. The influence of Russia, which also held the chief control of the Danubian principalities, was now predominant in Servia, and Milosh tried in vain to emancipate himself from it by an abortive attempt in 1835 to introduce a liberal charter. The influence of the English envoy, Col. Hodges, was overbalanced by that of the Russian, Vashtchenko, who succeeded in limiting and crippling the power of the prince by the establishment of a senate with exten-

sive privileges. Yefrem, who was placed at the head of the senate, was gained over by the enemies of his brother, who at the beginning of 1839 was almost a prisoner in the hands of the commander of the militia, Vutchitch. His other brother, Ivan, made an unsuccessful attempt to deliver him through the guards, and only hastened his downfall. Milosh was compelled to resign in favor of his son Milan, and left the country about the middle of June. Milan, however, survived his accession only a few weeks, and his younger brother Michael, who had accompanied his father into exile, was proclaimed his successor. Milosh, who had already protested against all that had happened, hesitated to allow his son to obey the call, but finally yielded, and remained in exile, living chiefly on his estates in Wallachia or in Vienna, where in 1845 he was saved from blindness through an operation for cataract. Michael, repairing with his mother to Constantinople, was favorably received by the Porte, proclaimed an amnesty, and made a triumphal entry into Belgrade, March 15, 1840. Here, however, he had to contend with numberless difficulties, with the opposition of the senate, the intrigues of Russia, of the widow of Czerny George, and of her son Alexander, the enmity of Vutchitch and Senator Petronievitch, who had been members of a regency before his arrival, and finally with violent popular commotions, directed at the same time against the ex-regents, the Russian and Turkish protectorate, and the abuses of the government. Unable to cope with his enemies, Michael in vain endeavored to terrify them by acts of cruel severity, and finally succumbed to a new insurrection under the lead of Vutchitch, in Sept. 1842. The house of Obrenovitch was now solemnly deposed, and Alexander Karageorgevitch proclaimed prince of Servia. Michael, who had fled to Semlin, now joined his father in Vienna, and, after some attempts to restore the power of his house by means of conspiracies or diplomatic intrigues, travelled extensively through Europe, and subsequently lived with his father in Vienna and Wallachia. Warlike preparations for an invasion of Servia, on the outbreak of the Russian war in 1853, had no result; but finally, after long years of exile, the two princes were restored to their country and to power by the revolution of Dec. 1858, which overthrew the rule of Prince Alexander, sending him into exile, and reinstated Milosh in his former dignity. The latter having been proclaimed prince by the skuptchina, Dec. 23, was confirmed by the Porte, Jan. 12 of the following year, and together with his son reentered Belgrade in triumph on Feb. 6. Having met with some diplomatic hostility on the part of Austria, Milosh during the ensuing war in Italy formed relations with the more revolutionary elements of Europe, and through the remainder of his reign maintained a firm attitude. In Sept. 1859, he personally opened the skuptchina, which among other enactments proclaimed the

right of the male line of the house of Obrenovitch to hereditary succession in the principality. This right was not acknowledged by the Porte, but Michael, after the death of his father (Sept. 26, 1860), found no difficulty in being personally confirmed as his successor.

O'BRIEN, WILLIAM SMITH, an Irish agitator, born in the county of Clare, Oct. 17, 1808. He belongs to a family ranking among the most ancient in Ireland, and deriving its descent from Brian Boroihme. He was educated at Harrow and Cambridge, in 1827 entered parliament for the borough of Ennis, county Clare, and in 1832 was returned for county Limerick, a constituency which he continued to represent for many years. The "repeal" movement of 1842-'8 enlisted his sympathies, and he distinguished himself by his strenuous opposition to the passage of the Irish arms act, Aug. 1843. The arrest of O'Connell and the other repeal leaders in the succeeding November, on charges of conspiracy and unlawful assembling, led to his becoming an active member of the repeal association. He now became a violent debater on questions affecting Ireland; and in May, 1846, for refusing to serve on committees of the house, he was committed to the custody of the sergeant-at-arms, who held him in confinement for several days. Upon the introduction by John O'Connell of his peace resolutions into the repeal association, in July, 1846, he left that body, with the "Young Ireland" or physical force party. He nevertheless abstained from counselling violent action; but the French revolution of 1848 gave an ultra tone to his views, and shortly after that event he made a violent speech in the house of commons threatening to establish an independent republic in Ireland. In April he accompanied a deputation sent by the "Irish Confederation" to Paris, to request aid on behalf of the "oppressed nationality of Ireland," and received abundant expressions of sympathy from Lamartine and his coadjutors, but no direct offers of assistance. Returning home in May, he aided in organizing a national convention of the Irish people, which however was not permitted to assemble. In May he was brought to trial, together with Thomas Francis Meagher, on a charge of sedition, but escaped conviction. His intemperate zeal soon hurried him into more overt acts of treason, and in July, 1848, he attempted a rising among the peasantry of Balingarry, which was promptly suppressed by the police. He took refuge in Tipperary, and on Aug. 5 was arrested near Thurles and conveyed to Dublin. He was brought to trial at Clonmel in October on a charge of high treason, convicted, and sentenced to death; but the sentence was commuted to transportation for life. In July, 1849, he embarked for Van Diemen's Land, where he remained until 1856, when the pardon accorded to the Irish agitators of 1848 enabled him to return home. In 1859 he paid a visit to the United States.

OBSERVANTS. See FRANCISCANS.

OBSERVATORY, a place appropriated for making observations upon any great class of natural phenomena. Observatories are of three kinds: magnetical, for observing the phenomena of terrestrial magnetism; meteorological, for observing the phenomena of atmospheric changes; and astronomical, for conducting observations of the heavenly bodies. The purposes of the astronomical observatory are to scrutinize celestial objects and phenomena which, on account of their distance or minuteness, are invisible or imperfectly visible to the naked eye, and to afford accurate measurement of angles and spaces in the heavens. For effective work, it is necessary that there should be a fixed support for the instruments, and exemption from tremors and atmospheric disturbances. To secure the first, the instruments are to be firmly planted on stone piers, with a foundation of clay or rock if possible, or deeply bedded in solid ground, and completely isolated from all other bases of support and from the building which covers them. To secure the second, a situation is to be chosen secluded from ways of travel and business. It is important that the locality be dry, of equable temperature, as nearly exempt as possible from fogs, clouds, &c., and screened from high winds so far as is consistent with a free view of the horizon. The instruments on which exact astronomy is founded are the transit and its clock for obtaining and keeping exact time, and the mural circle for measuring the meridian distances of stars from the zenith. There are also several other principal instruments, viz.: the equatorial, which admits of being directed to any part of the heavens, and is adapted to some of the most interesting departments of modern astronomy; the heliometer, for taking the most difficult micrometric measurements; and the altitude and azimuth circle, for determining these elements of a star's place. Beside these, every well equipped observatory has a variety of lesser instruments selected according to the special work to be carried on. Barometers, psychrometers, thermometers, chronometers, &c., are also important accessories. Of the more ancient instruments only the zenith sector and the mural quadrant are now retained. The American method of recording observations by means of electro-magnetism has introduced a novel and elegant kind of apparatus among the equipments of the observatory, and has greatly increased the efficiency of the labors of the practical observer.—The first epoch of modern practical astronomy begins with the labors of Tycho Brahe at his castle of Uraniburg near Copenhagen (1576). From these labors Kepler drew the argument of his demonstration of the three great laws of motion. But Uraniburg has disappeared; hardly its site is known. Of the great astronomical institutions extant, the imperial observatory of Paris is the oldest. Built in 1667-'71 by order of Louis XIV., and designed by Claude Perrault, the famous architect

of the Louvre, it was an edifice of great magnificence, but unfortunately ill adapted to the purpose for which it was intended. Dominique Cassini, an Italian, who had been invited to Paris to adorn the court of the "grand monarch," was its first director. Here Picard, whose accurate measurement of an arc of the meridian (1669) furnished Newton with the basis of his demonstration of the theory of universal gravitation, labored from 1673 till his death in 1682, with great usefulness to practical astronomy. This institution, in recent times, attained a high degree of efficiency under the directorship of Arago. It is now directed by Leverrier. The royal observatory at Greenwich began operations in 1676, with Flamsteed for astronomer royal, whose observations supplied Newton with the means of developing his great principle of matter. Professor Airy, the present incumbent, succeeded to the directorship in 1835. The Tuscan observatory in Copenhagen was built in 1704, for Roemer, the discoverer of the velocity of light. Peter the Great caused an observatory to be erected in 1725 at his capital, and the French astronomer De Lisle was invited to be its director. In 1830 the emperor Nicholas declared that "the honor of the country appeared to him to demand the establishment, near the capital, of a new astronomical observatory, conformable to the actual state of science, and capable of contributing to its ulterior advancement." Accordingly a building was erected in 1839 at Pulkowa, a small town 10 m. S. W. from St. Petersburg, on a scale of unprecedented magnificence. The cost for erection and equipment was about \$500,000, and \$50,000 are annually appropriated from the imperial treasury for its maintenance. It is the best endowed and the most perfectly organized of all European observatories. Attached to it are a very fine library and workshops for making requisite repairs and alterations in the instruments. In 1844 there were no fewer than 108 persons, including the families of those employed, residing within its precincts. M. Struve, its director, has given a complete description of this establishment in a magnificent work entitled *Description de l'observatoire astronomique central de Pulkowa* (2 vols. fol., St. Petersburg, 1845). The labors of Sir William Herschel at his private observatory at Bath and afterward at Slough, near Windsor, constitute an era alike in speculative and in practical astronomy. The observatory at Dorpat, Russia (about 1811), was the scene of the elder Struve's researches in sidereal astronomy, which have rendered his name illustrious, and of the no less useful labors and speculations of Mädler in the same department, who succeeded to the directorship on Struve's appointment (1839) to the new establishment at Pulkowa. The observatory of Königsberg (1818), under the directing genius of Bessel, who first dropped the plummet into the regions of the fixed stars by means of the parallax of 61 Cygni, became second to none during the

present century for its contributions toward the improvement of every branch of astronomy. The observatory of Berlin (about 1884) is important on account of the labors of Encke. Here the planet Neptune was first seen by Dr. Galle, Sept. 23, 1846. Of the British public establishments of the first class, there are, beside that at Greenwich, already mentioned, the Radcliffe observatory at Oxford (1774), the Rev. R. Main director since 1859; that at the Cape of Good Hope (1821), memorable for the successful researches of Professor Henderson, of Edinburgh, in determining the parallax of Alpha Centauri, and which has been under the direction of Mr. Maclear since 1833; that at Cambridge (1824), Professor Challis director since 1835; and the royal observatory of Edinburgh (about 1825), Professor Piazzi Smyth director since 1844. There are many other European observatories justly famous; for example: at Bonn, the scene of Argelander's splendid labors and triumphs; at Bremen, where Dr. Olbers discovered the 2d asteroid, Pallas, in 1802, and the 4th, Vesta, in 1807, and for 15 years directed the search for new planets; at Bilk, under the directorship of Dr. Luther; at Altona, Athens, Breslau, Florence, Göttingen, Hamburg, Leipsic, Munich, Ofen, Rome, Santiago, Seeburg near Gotha, Upsal, Vienna, and many others. The English have also observatories at Madras, India, and at Sydney in New South Wales, formerly at Paramatta. An active and intelligent interest prevails throughout the British empire for the promotion of practical astronomy. This is, in a great degree, due to the influence of the royal astronomical society, an offshoot (1820) of the royal society. This interest is shown in the establishment of numerous private observatories which have enriched science with many brilliant discoveries. Thus, Lord Rosse has erected at Parsonstown, co. of Louth, Ireland, the most stupendous instrument known, of incomparable performance, whose disclosures are of the profoundest interest, and have furnished new arguments in the nebular controversy. Lassell, with his beautiful reflector established at Liverpool, was the first to detect a satellite of Neptune, and contests with the Bonds at Cambridge, Mass., the honor of the discovery of Hyperion, the 7th in order of the satellites of Saturn. At the private observatory of George Bishop, Esq., in Regent's park, London (1836), J. R. Hind, Esq., has labored since 1844 with great success. To these may be added Admiral Smyth's observatory at Bedford, now dismantled; Sir John Herschel's late establishment at Feldhuysen, Cape of Good Hope; and those of Messrs. Carrington, Dawes, Cooper, and others.—According to John Quincy Adams, there were 130 astronomical observatories in Europe in 1825, while in the United States there were none prior to 1830. That enlightened statesman, in his first presidential message (1825), strongly urged upon congress the establishment of a national observatory; but the project met

with general disfavor and ridicule. The first telescope used in this country for astronomical purposes was set up in 1830 at Yale college. The first observatory building was erected in 1836 at Williams college, Mass., by Professor Hopkins. Two years later the Hudson observatory was organized in connection with the Western Reserve college, Ohio, Prof. Loomis director. About the same time the high school observatory at Philadelphia was established, which introduced a class of instruments superior to any before employed. In the hands of Messrs. Walker and Kendall, says Prof. Loomis, in his "Recent Progress of Astronomy in the United States" (New York, 1851), it became celebrated not only in America, but also in Europe. It was rebuilt with the high school in 1854. The West Point observatory, under the care of Prof. Bartlett, and the national observatory at Washington, under the superintendence of Lieut. Maury, soon followed. At Georgetown, D. C., an observatory was erected in 1844, and about the same time that at Cincinnati began operations with instruments of admirable performance. Here Prof. Mitchell, to whom the observatory owed its existence, has made a number of interesting discoveries, and has performed a valuable service by the remeasurement of Struve's double stars south of the equator. The corner stone of the building was laid in 1843 by the venerable John Quincy Adams. The observatory at Cambridge, established a year or two later, is furnished with one of the best equatorials in the world. By means of it Messrs. William C. and George P. Bond have added to the treasures of astronomical science a new satellite of Saturn, already alluded to; the fact of the semi-transparency of the inmost zone of the ring of the same planet; the conjecture, established by Prof. Peirce's demonstration, of the fluidity of the ring; improved accounts of the nebula; and observations of new planets, and of the satellites of Saturn, Uranus, and Neptune. At Ann Arbor, Mich., an observatory has been established (1854) on a very liberal scale, chiefly through the exertions of Chancellor Tappan of the university of Michigan. Dr. F. Brünnow is its able director. The most recent establishment of the kind is the Dudley observatory at Albany, Prof. Mitchell chief director since 1859. (See DUDLEY, CHARLES EDWARD.) In addition to the foregoing, celestial telescopes have been set up at Nantucket, Mass., where Miss Maria Mitchell has won a European fame; near Darby, a few miles from Philadelphia, by the late John Jackson; at Tuscaloosa, Ala.; at Charleston, S. C., by Prof. Lewis R. Gibbes; at New York city by Mr. Rutherford, and another by Mr. Campbell; at Newark, N. J., by Mr. Van Arsdale; at Philadelphia, by the Friends; at Amherst college; at Dartmouth college, due chiefly to the munificence of George C. Shattuck, Esq., of Boston; at Hamilton college; and at the Packer institute for young ladies in Brooklyn, L. I.—Apart from the

more elevating uses of the astronomical observatory in widening the boundaries of knowledge and in offering to the contemplation of mankind the most exalting views of nature, there are many considerations fitted to commend it to the attention of a commercial people. 1. It furnishes the only sure means of determining time with precision, and of accurately correcting chronometers, which are almost exclusively relied on at sea for ascertaining the longitude from day to day. 2. By extending a knowledge of the heavenly bodies, which are the unchanging beacons of the mariner on every water, it directly contributes to the security of commerce. 3. Its great office being to bring to light new truths, it is a living testimony against the contented retailing of other men's ideas, and thus stimulates the spirit of invention, discovery, and commercial enterprise, no less than of educational reform.

OBSIDIAN, lava that has become glassy by rapid cooling. It is usually composed of felspar, or that mineral and augite, but sometimes of others also. Its peculiar characteristics are its glassy lustre, high polish, and hardness sufficient to scratch glass. It occurs in immense quantities about volcanoes, active or extinct, and was known to the ancients. The Greeks called it *σφαιανός λίθος*, as is supposed by some from *σφαις*, in allusion to its translucence. Pliny, however, derives its name from one Obsidius, who is said to have brought it from Ethiopia. It was used by the ancients for mirrors, and for various ornamental purposes. It is the material which the Mexicans used under the name of *itztli* for their knives, razors, and serrated weapons, and implements with which they fashioned the alabaster and other stone work of their buildings. The pointed fragments were made into arrows, specimens of which as well as of their knives are to be seen in the collection of the New York lyceum of natural history, and in that of Columbia college. The stone has been used for ornamental purposes, particularly as mourning jewelry, and is esteemed chiefly on account of its high polish; but by reason of its brittleness it requires to be worked with particular care. It is made into ear rings, brooches, knife handles, snuff boxes, &c. The iridescent variety is sometimes cut in cabochon and set in rings. This commands a high price; its color is a peculiar greenish yellow. The colors of obsidian are numerous; but each piece commonly has but one shade.

OBSTETRICS (Lat. *obstetrix*, a midwife), the art and science of midwifery, or, as Velpeau defines the word, the aggregate of knowledge relative to the reproduction of the human species. It includes the anatomy, physiology, pathology, and therapeutics peculiar to women, together with the science of reproduction, its phenomena, and its consequences, parturition, and puerperal and infantile diseases. Its object is necessarily complex, for it appertains to two beings at the same time. It consequently has

a double mission: 1, to render possible, easy, and regular, exempt from all abnormal suffering and all danger, the accomplishment of the numerous functions which affect directly or indirectly generation from birth to the age when the procreative faculty becomes natural to the human female; 2, to direct and defend from all harm the delicate and precarious health of the infant during its early period of existence, and particularly during lactation. Thus far it appertains to medicine. But the operative duties of obstetrics are of a surgical character. Labor is a natural function, and happily the intervention of art is rarely demanded, so that no great amount of knowledge is necessary to assist as an intelligent spectator a spontaneous and happy parturition. But to foresee, prevent, or remove all possible dangers, to overcome serious obstacles when they exist, to resolve the many difficult and trying questions that may arise, demand not less acquirement or less judgment than the other departments of medicine. The important part which woman takes in generation consists in successive acts which are accomplished in her. One of the germs or ova, enclosed in the appropriate organ, the ovary, undergoes, after sexual intercourse, a modification by which it receives the power to grow and develop itself. This modification constitutes fecundation. The ovum is soon after transported to a hollow organ, the uterus. This organ, undergoing remarkable changes, retains the fecundated product, and furnishes it the indispensable materials for its nourishment and growth. This product itself gradually becomes a being like that from which it emanates, that is to say, first an embryo, and next a fœtus, when it acquires all the necessary powers for exterior life. This succession of the various phenomena constitutes gestation or pregnancy. When these powers are acquired, the new being is expelled by a spontaneous action of the same organ which has contained, protected, and nourished it; and during this expulsion, known by the name of labor or parturition, in order to come to the light, it is obliged to traverse a complex and resisting cavity, the pelvis, which is not accomplished without pain. But still another tie attaches the new being to the maternal organization, even after its birth, for it still requires for some time the aid of the breasts, organs designed only for this function, which furnish the necessary elements for its nutrition. This last act is lactation. The development of these phenomena is preceded and prepared for by particular modifications which the ovarian vesicles undergo. A bloody periodical discharge, called menstruation, of which the uterus is the source, ordinarily coincides with this modification of the ovarian vesicles.—This brief exposition of the principal and successive phenomena of generation in woman, proves that obstetrics includes: 1, anatomy, the organs which concur to the execution of the acts above described; 2, the physiological phenomena, the mode in

which these acts are performed; and 3, the pathology of these organs. As regards the anatomy, it is sufficient here to say, that the female organs subservient to generation are the ovaries, the principal function of which is the secretion of the ovule or female germ; the Fallopian tubes, designed to receive the ovule and conduct it into the cavity of the uterus; the uterus or womb, a kind of receptacle, whose office it is to contain the fecundated germ during its period of development, and to expel it immediately afterward; and finally the vagina, a membranous canal extending from the neck of the uterus to the external organs. Most of these organs are situated within a large cavity, the walls of which are composed of bones and soft parts; this is termed the cavity of the pelvis. The functions of these organs are menstruation, conception, gestation or pregnancy, and labor or parturition. These functions are limited to certain periods of life, *i. e.*, from about the 15th to the 45th or 48th year. Some few girls, however, menstruate as early as the 11th, and some women as late as the 54th year. The generative faculty in women coincides with the function of menstruation. The earliest age at which pregnancy is positively known to have occurred is 11 years. The latest period at which parturition at the full term of gestation is satisfactorily known to have taken place is probably 54 years. The most prolific period, according to Dr. Bland, is between the ages of 26 and 30 years. The signs of pregnancy may be divided into two classes: 1, those which result from the derangement of some functions, as suppression of the menses, nausea and vomiting, mammary pains, vitiated tastes, &c.; 2, those which are to be detected only by a physical examination, as the change of color around the nipple, called the areola, the enlargement of the abdomen, the movements of the fœtus, the position of the uterus in the abdomen, *ballotement* or reperussion, and the signs derived from auscultation, and those ascertained by touch, of the change in form, density, and position of the neck of the womb. There are some diseases which may give rise to an unjust suspicion of the existence of pregnancy, particularly those that produce enlargement of the abdomen. The chief of these are spurious pregnancy, a very curious and not very infrequent phenomenon, ovarian dropsy and dropsy of the abdomen, fibrous tumors and large polypi of the uterus, enlargement of the liver, kidney, spleen, &c., and distention of the cavity of the uterus with blood, water, or air.—It is usually admitted that the ordinary duration of pregnancy is 10 lunar months, or about 9 calendar months, or from 274 to 280 days. It has however long been a disputed point whether gestation may not be protracted beyond this point. The weight of authority is now in favor of the opinion that it may in some instances be prolonged to the 300th and even the 308th day. The abrupt termination of pregnancy by the premature expulsion of the product of con-

ception is of frequent occurrence, the number of mothers who pass through the child-bearing epoch of life without aborting once or oftener being small. The expulsion of the ovum may take place at any period of gestation. When it occurs during the first 16 weeks, it is termed an abortion; when between the end of this period and the 28th week, a miscarriage; and when after the latter period, but before the completion of the full term, a premature labor. It may be stated as a general law, that when the fœtus is expelled before the 28th week of pregnancy, it either dies immediately or soon after birth. The causes of abortion, miscarriage, and premature labor are very numerous, but they may be classified under 5 heads, *viz.*: 1, the accidental; 2, some deranged state of the mother's health; 3, some disease of the uterus or its appendages; 4, some disease of the embryo or fœtus or its membranes; 5, when induced for criminal purposes, or as a necessary therapeutic measure to preserve the life of the mother. The danger to the life of the mother depends somewhat upon the period when the abortion or miscarriage occurs. In the 1st or 2d month, the ovum with its appendages generally escapes without producing any noticeable illness. In the 3d and 4th months there is often considerable danger from hæmorrhage. The danger then becomes lessened after the 5th month. The cause of the abortion or miscarriage must also influence the prognosis. Thus, when it originates from some slowly operating maternal or fœtal disease, it is attended with much less serious consequences than when it is produced suddenly by an accident or by the exhibition of some irritating medicines, or by puncturing the membranes. Tardieu reports 84 cases of criminal abortion, in which the death of the mother resulted in no fewer than 22. So, too, an abortion occurring during the progress of an acute inflammation of the lungs, brain, heart, liver, or bowels, forms a highly dangerous complication.—The condition of pregnancy produces different results on the maternal system, according to the constitution and peculiarity of the individual. Occasionally, it results in a salutary change in the entire system, better health being then enjoyed than at any other period. In a majority, however, it induces disagreeable symptoms, amounting merely to discomfort in some individuals; in others, so great as to injure the health and even destroy life. The diseases of pregnancy have been ranged under the following heads, *viz.*: lesions of digestion, as anorexia or loss of appetite, vomiting, sometimes so persistent as to destroy life, constipation, diarrhœa; lesions of the circulation, as plethora, hydræmia, varices, hæmorrhoids; lesions of the secretions and excretions, as pytalism, albuminuria, anæmia, leucorrhœa, dropsy of the cellular tissue, dropsy in the great cavities of the body, dropsy of the amnion (a morbid collection of water in the uterus); lesions of locomotion, as relaxation of the pelvic articulations,

inflammation of the pelvic articulations; lesions of innervation, as modifications of the organs of sense, blindness, deafness, vertigo, syncope, pruritus of the vulva, and displacements of the uterus.—Labor or parturition is that function which consists in the spontaneous or artificial expulsion of a viable fetus through the natural parts. The phenomena accompanying the performance of this function may be divided into two classes, the physiological and the mechanical. Previous to the commencement of labor, there are some precursory phenomena, indicating its approach. These appear in some cases during the last fortnight of pregnancy, in others only 5 or 6 days before labor commences. They result from the dilatation of the internal orifice of the womb. The uterus, which before extended up to the stomach, sensibly sinks lower, the mechanical obstruction to respiration is removed, the stomach is no longer oppressed, but the bladder and rectum become irritable, and locomotion is more difficult. The physiological phenomena of labor are divided into 3 stages; the 1st stage ends with the dilatation of the mouth of the womb, the 2d with the expulsion of the fetus, and the 3d with the delivery of the placenta or after birth. The symptoms of the 1st stage are intermittent pains, resulting from the uterine contractions, discharge of a glairy mucus, formation of a bag of waters, and gradual dilatation of the neck of the womb. The pains of the 1st stage are usually borne with more impatience than those of the 2d. The cries which accompany them are sharp, and resemble those of any other species of suffering; those of the 2d stage seem to be suppressed like those of a person carrying a heavy burden. The use of the glairy discharge is to moisten and lubricate the parts over which the child has to pass, to increase their suppleness and extensibility, and make it more easy for the ovum to slide over the surfaces. Where these discharges fail to take place, the dilatation of the mouth of the womb is always more painful and slower, and the organs are more disposed to become inflamed. The name of bag of waters is given to a protuberance formed by the membranes in the upper part of the vagina during labor. During the presence of a pain, it is hard, tense, and elastic; after the contraction is over, it becomes wrinkled and contracts or disappears. It eventually breaks, sometimes early in the 1st stage, and in other cases not until late in the 2d stage, when the contained fluid escapes. The duration of labor is exceedingly variable, even when no obstacle opposes its natural course. Some women are delivered in an hour or two, while others are not for several days; and between these two extremes there is every intermediate grade. In the first confinement, the average length of labor is usually from 10 to 12 hours; but in at least one case in 5, it may not terminate under 15, 18, or even 24, and this without any injury whatever resulting either to the mother or child. Women

who have had children are delivered much sooner, only suffering, in ordinary cases, about 6 or 8 hours. The duration of the 1st stage is to the 2d as 2 or even 3 to 1; but this law is subject to many exceptions. The 3d stage ought to be completed within 30 minutes.—To understand the mechanical phenomena of labor, it is necessary first to define the terms presentation and position. We designate by the term presentation the part of the child that first offers at the entrance of the pelvic cavity; and by the term position, the relations of the presenting part to the different points of the entrance to the pelvis. The attitude of the child in the uterine cavity is in a great majority of cases such that the direction of the trunk is parallel with that of the mother, and one extremity forms the most dependent part. In by far the largest proportion of cases, it is some portion of the head which first offers at the entrance of the pelvic cavity. If the head is flexed, it is called a vertex presentation. If the head is extended back, the chin far removed from the breast, it is a face presentation. When the other extremity presents, the legs are usually flexed on the thighs and the latter on the abdomen; the whole breech may therefore offer at the entrance of the pelvis, or one or both feet or knees. As the mechanism of labor must be the same in all these cases, they are all included under the term pelvic presentations. But it may happen that, instead of one of the extremities offering, some portion of the trunk may offer, the child lying transversely in the uterus, and this may be either some point of the right half or of the left half of the trunk. We have then 5 primary presentations, one of the head, one of the face, one for the pelvic extremity, one for the right lateral plane, and one for the left lateral plane. The presentation of the head is incomparably more frequent than all the others. According to Mme. Boivin, in 20,857 cases it occurred in 19,780. The fetus presents by the face, on an average, once in 250 labors. The pelvic presentation occurs once in 30 or 35 labors. The trunk presentations are a little less rare than the face, occurring about once in 200 cases. As a law it may be stated that trunk presentations always demand the interposition of art to accomplish delivery. The other presentations generally terminate spontaneously. In order that a labor may terminate without foreign aid, a considerable number of conditions are required. On the part of the mother, there must be no fault or deformity of the pelvis, no serious affection of the womb, and the organ must possess a certain energy; the general powers of the system must not have been exhausted either by a profuse hæmorrhage or any long continued disease; there must be no affection making it dangerous for the woman to give herself up fully to the efforts that she is compelled to make; and no accident must supervene during the labor. On the part of the child, it is important that it

should descend with the head, the face, the feet, the knees, or the breech foremost, and that it should not be of a size disproportionate to the capacity of the pelvis. About one case in 80 requires in some form artificial aid to complete a happy delivery for the mother and child.—The obstetric operations required for cases of difficult and dangerous labor, either to save the life of the mother or child or both, are: 1, induction of premature labor, an operation of great importance and value in certain cases; 2, version or turning, that manual operation by which one presentation is substituted for another less favorable; 3, the vectis, to correct malpositions or aid the natural rotations of the head; 4, delivery by forceps; 5, craniotomy, an operation by which the life of the child is sacrificed in order to save the mother; 6, the Cæsarean section, in which the child is extracted through an incision in the walls of the abdomen and uterus. The dangerous complications which may arise in connection with labor are: prolapse of the cord or funis, an accident very fatal to the child; flooding or hæmorrhage; retention of the placenta; convulsions; rupture of the uterus; lacerations of the vagina or perineum; and inversion of the uterus.—The progress of obstetrical science and the improvement in the art have been very marked within a few years past. We have no means of knowing what proportion of women formerly died in childbirth. According to Tanner, "the 20th annual report of the registrar-general of births, deaths, and marriages in England, shows that in the year 1847 the birth of every 10,000 living children was the death of 60 mothers, whereas in 1857 it was only fatal to 42; hence 18 mothers are now saved in every 10,000 children born. Since 1848 the decline has been progressive, the numbers per 10,000 being 61, 58, 55, 52, 47, 47, 44, and 42 in 1857. That this happy result is not accidental, but is in a great measure due to the progress of science, cannot be doubted." Among the most striking modern improvements in obstetrical science and practice, may be mentioned the application of auscultation to obstetrics; a more perfect knowledge of the mechanism of labor, and of the management of placenta prævia; the introduction of chloroform; the induction of premature labor; an increased frequency in the use of the forceps, and a less frequent resort to craniotomy; and the substitution of version in some cases, where either craniotomy or the long forceps were formerly employed.

OCCAM, or OCKHAM, WILLIAM, an English scholastic philosopher, born in the village of Occam, in Surrey, in the latter half of the 13th century, died in Munich, April 7, 1347. He was educated in Merton college, Oxford; refused in 1300 the archdeaconry of Stowe; obtained in 1302 the first prebend of Bedford, and in 1305 that of Stowe, which he resigned in 1319; and after 1322 was provincial of the Franciscans in England. He was expelled from

Oxford for exciting tumults among the students, and repaired to Paris, being already eminent for erudition and scholastic subtlety. He joined the Franciscans, was a disciple of their chief Duns Scotus, and, having become a public teacher as professor of theology in the university of Paris, was immediately recognized as the head of the party which was assailing at once the traditions of politics, religion, and philosophy. He was styled "the invincible doctor," revived the doctrine of nominalism, and undertook the advocacy of King Philip the Fair in his contest with Pope Boniface VIII., maintaining the independence of princes in secular affairs. At Perugia in 1322 he argued that Christians neither individually nor in community should be the possessors of property. His manifesto, entitled *Disputatio super Potestate Ecclesiastica Prælati atque Principibus Terrarum Commissa*, was condemned by the pope; but, supported by Michel of Cesena, general of his order, he continued vehemently to assail the practices of the holy see. Summoned with his disciples in 1328 by Pope John XXII. before the court of Avignon, he escaped from penalty for his opinions by a precipitate flight to the court of the emperor Louis the Bavarian, who received him with the greater favor in consequence of his own quarrel with the pope. There he remained till his death, supporting the cause of the emperor against the papal claims, and saying to his associates: *Tu me defendas gladio, ego te defendam calamo*. He was in his age the champion of the Franciscans and the nominalists against the Dominicans and the realists. He caused the weight of ability, during the later and less flourishing period of scholasticism, to be with brief interruptions on the nominalist side. By denying the objective existence of universal conceptions, and maintaining that knowledge was subjective, he exposed himself to charges of scepticism and empiricism, which his opponents more than once successfully availed themselves of. Yet he threw off the despotism of scholastic dogmas, and introduced into philosophy a wider range and a freer spirit. In theology he rejected the scholastic proofs of the divine existence and attributes, which he regarded as matters of faith alone. Yet he proposed as a sufficient proof of the being and agency of God the fact of the continuance of all things in their original state. In psychology he refuted the current hypothesis of objective images which were deemed necessary to a theory of perception. In ethics he adhered to the Scotist doctrine that the ground of morality is the subjective will of God. His philosophical writings are: *Super Libros Sententiarum Subtilissimæ Quæstiones* (Lyons, 1495); *Quodlibeta Septem* (Paris, 1487); *Summa totius Logica* (Venice, 1591); *Quæstiones in Libros Physicorum* (Strasbourg, 1491); and *Expositio Aurea super totam Artem Veterem, videlicet in Porphyrii Prædicabilia et Aristotelis Prædicamenta* (Bologna, 1496).

OCCOOM, SAMSON, an Indian preacher, born in Mohegan, New London co., Conn., about 1723, died in New Stockbridge, N. Y., in July, 1792. When 19 years old he entered the Indian school of Mr. Wheelock at Lebanon, and remained there 4 years. In 1748 he kept a school in New London, but shortly after removed to Montauk, Long island, where he taught and preached to the Indians. In 1766 Mr. Wheelock sent him to England as an agent for Moor's Indian charity school. Being the first Indian preacher who had visited that country, he was successful in attracting large audiences and obtaining donations. After his return to America, Occoom preached at various places, passing his latter years within the bounds of the Albany presbytery. He wrote an account of the Montauk Indians, still in MS., and published a sermon on the execution of an Indian at New Haven in 1772.

OCCUPANCY, the possession of property. Property is acquired either by the natural or by the civil or positive law. The latter system determines the modes of derivative acquisition. Original acquisition must have been founded upon the law of nature. "That which belongs to no one," says Gaius, "is given by natural reason to him who takes possession of it; that is to say, to the occupant." Occupancy may therefore be defined as the title by which one acquires the property in an unowned thing by taking possession of it with the intention of appropriating it to his own use. Three elements are here to be observed: 1, that the thing to be acquired be *res nullius*, the property of no man; 2, that it be taken by the acquirer *corpore*, that is, actually into his power; and 3, that he take it *animo*, or with the intention of holding it and using it as his own. The principles which the Roman law applies to the acquisition of particular things, the law of nations applies to the acquisition of territory and jurisdiction by states. By the Roman law, as we have seen, property is acquired through occupancy when that is made *corpore et animo*, that is, by an outward act signifying the intention of possession. Yet, as possession or occupancy must always be adapted to the subject, and as physical contact is not always possible, but any act which imports ownership is sufficient, so a state may take possession of an entire vacant country without actual occupation of every part of it. But by a mere declaration to that effect, no state can take valid possession of territory which it cannot use and therefore does not, even constructively, occupy. Merely to set up a cross or to erect any other monument upon every coast which a navigator touches, is not to take such a possession as subsequent explorers are bound to respect. The law of nations will not acknowledge the propriety and sovereignty of a nation in uninhabited countries, unless it make actual use of them; for use most strongly imports an intention of ownership. The use which occupancy requires is of course various. Thus, provided other

racess do not require and demand the room, it is said that a pastoral nation may justly claim the ownership of a larger territory than one which is devoted to the pursuits of agriculture. They make a use of the land which is conformable to their mode of life; they occupy in their fashion and therefore possess the whole land, and no other nation has the right to dictate to them any other mode of using it. By this principle, if the English and French trappers and fur traders were regarded as mere hunters, the American Indians might justly have excluded them from their hunting grounds; for, as hunters, the Indians had the prior and superior right of occupancy. But as the newcomers were the forerunners of a higher civilization, their establishment of forts and trading stations, though a form of possession but little superior to that of the Indians, yet implied a more complete occupation, and, so far as the lands were needed by the whites, defeated at least the exclusive Indian use. Certainly, as against future settlers and other nations, this mode of occupancy of the traders gave them a preference; because it was then the only practicable exercise of proprietary acts, and indicated sufficiently that a beneficial use was intended to be made of the whole region through which their traffic was in this way extended. On these principles Great Britain claimed that the establishment of a few trading factories on the shores of Hudson's bay gave its subjects an exclusive right by occupancy as far as the Rocky mountains. As then the beneficial use is the criterion of occupation, this will vary with the character of the territory to be acquired. The occupation which we have just considered differs as widely from a pastoral as that does from an agricultural occupation; and the extent of contiguous country to which an actual settlement gives prior right will differ in all these cases. In regard to agricultural colonies like those on our Pacific coast, it has been argued in diplomatic correspondence with Great Britain that much depends on the magnitude and population of the settlement, and on the facility with which the vacant adjacent land may within a short time be occupied, settled, and cultivated by such population, compared with the probability of its being occupied and settled from any other quarter.—The principles of occupancy have a partial application in the American doctrine of preemption. Our preemption laws are expressly framed with the intention of giving preferences in the allotment of the public lands to "settlers" and "occupants." These words have been officially construed and declared to mean those who personally cultivate and reside on, or who personally cultivate, use, and manage the public lands. In short, to constitute a settler or occupant within the meaning of these laws, the party must have a direct personal connection with the land which he claims. Residence on the land is the best evidence of this, but this is not indispensable.

When a settlement and occupation is intended to be made, and is actually made, so far as circumstances permit, the requirements of the law are satisfied. Under the existing laws, an agricultural preëmtor may enter 160 acres or a quarter section of land, provided only he make improvements and erect a dwelling house upon it. Cultivation of the whole section is evidently not a precedent condition of the settler's right. Between the moment when he turns the first sod and that when the whole claim is enclosed and brought under actual cultivation, much time must necessarily elapse. But the occupant's right is fixed by his very first act of improvement done with the intention of ownership; and if he furnish sufficient *indicia* of this intent, this right and the benefits of prior occupancy will be assured to him.

OCEAN, the great body of salt water which surrounds the continents and covers more than three fifths of the whole surface of the globe. By the configuration of the lands which rise above its surface, it is partially separated into a number of divisions, known by distinct names, as the Atlantic, Pacific, Indian, Arctic, and Antarctic oceans, for a more particular account of which reference may be made to the separate articles under those names. The last named is divided from the Pacific, not by intervening bodies of land, but by the imaginary line of the Antarctic circle. The nearly landlocked arms of the ocean are designated as seas, bays, and gulfs. All these bodies of water are united together in one great system, and are kept of nearly uniform composition, notwithstanding numerous local causes of change, chiefly by means of great currents which circulate through them. Some of these currents are of vast extent, spreading over a large part of the oceans to which they belong, and with but slight variations they move without cessation in the great system of the circulation of the waters. Some are submarine, moving in one direction, while the waters at the surface move in another. They are set in motion by differences of temperature, by planetary attraction, rotation of the earth, the trade winds, &c. Prominent among the important objects they serve, beside that already named of equalizing the quality of the sea water itself, is the effect they have upon the climates of the globe, the waters warmed by the tropical heats carrying and diffusing their elevated temperature into colder regions, and those from the arctic seas spreading, with the icebergs which they float along, a portion of the excessive cold of those inhospitable climes over the temperate latitudes. In extreme latitudes, arctic or tropic, the sea acts in various ways to moderate the excessive cold or heat. It is the chief source of the vapors that are wafted over the earth and fall in rain, feeding the rivers, which in turn yield back to the ocean its waters. —A striking feature in the ocean is its saltiness. This is owing to the presence of chloride of sodium (common salt), which, with small quantities of sulphate of magnesia, sulphate and car-

bonate of lime, iodine, and bromide of magnesium, forms about $\frac{1}{10}$ of the total weight of the aqueous solution. The proportion of salt varies in different places, sometimes exceeding 4 per cent. It is large where the water is deepest, but does not increase with the depth. Though inland seas generally contain less salt, the Mediterranean contains more of it than the ocean itself; the specific gravity of its water east of the straits of Gibraltar has been found to be 1.0888, while that of water from the ocean west of the straits was 1.0294. The specific gravity of sea water near the equator is about 1.0277. The saline elements of the water may be derived from geological formations consisting in great part of such elements; but strata of this character always bear evidence of being deposited from ancient oceans, so that this derivation throws no light upon the real source of the salt. In different parts of the ocean various substances introduced by great rivers modify locally the composition of its waters; and from the strata beneath the sea there no doubt emanate mineral springs, such as appear upon the land. Springs of fresh water are known in many places to rise up through the salt water, and some of them even furnish supplies to vessels.—The color of the sea, commonly described as bluish green, is by no means uniform, and the reason of the changes of its hue is unexplained. In the tropics it is at one time an indigo blue, then a deep green, and again a slate gray; the clouds appear to have no influence in producing these changes. Upon some coasts a reddish or purplish hue is apparent, and elsewhere the water appears black, or white, or beautifully transparent. In the fiords on the coast of Norway the crystal clearness of the water is wonderful; at the depth of 20 or 25 fathoms small objects may be discerned upon the sandy bottom, apparently magnified by the water itself.—The depth of the ocean is very uncertain, and has been greatly overrated. The difficulties of deep sea soundings are referred to in the article ATLANTIC OCEAN; and they are of such a nature that little dependence can be placed on results exceeding 2,000 fathoms or 12,000 feet. Lines have been run out several miles, but the weights used could scarcely have drawn them down more than a mile and a half on account of the friction of the lines through the water. Currents of water at different depths act upon them, and carry them off from a vertical course. From calculations made by officers of the U. S. coast survey, based on observations of the time in which waves raised by an earthquake in Japan on Dec. 28, 1854, were transmitted to San Francisco and San Diego in California, the mean depth of the Pacific would be from 2,100 to 2,500 fathoms. With the depth the pressure increases at the rate of about 15 lbs. to the inch in every 34 feet. The water however is so little compressible, that the comparative weight of any body and of the water at different depths remains very nearly the same; what would sink therefore near the

surface should continue to sink at all depths. The pressure, however, becomes enormous far below, and porous bodies, as wood, which are sunk and drawn up, are entirely saturated with water, which, taking the place of the lighter air that filled them, causes the wood to sink. Soundings have proved that the bottom of the sea presents almost as irregular a surface as the land. Shoals are the more elevated plateaus in the ocean. Their surfaces slope away into the deep water, and in some localities the plummet sinks suddenly at their sides to great depths. The slopes of precipitous mountains in the sea, as those of St. Helena, are continued below the water, and at 150 feet from the apparent base of the precipitous cliffs no bottom has been found at 150 fathoms.

OCEAN, an E. co. of N. J., bordering on the Atlantic, and drained by Meteteunk and Tom's rivers and several creeks; area, about 550 sq. m.; pop. in 1860, 11,209. A sand beach from $\frac{1}{2}$ to 1 m. wide extends along the coast, and between it and the mainland are two lagoons, Barnegat bay and Little Egg Harbor inlet. The surface is level, and much of it covered with pine forests; the soil is light and sandy. Iron is found and manufactured in large quantities in the north. The agricultural productions in 1850 were 108,474 bushels of Indian corn, 22,083 of rye, 38,219 of potatoes, 6,679 tons of hay, and 78,059 lbs. of butter. There were 5 grist mills, 16 saw mills, 19 charcoal works, 22 churches, and 2,189 pupils attending public schools. Capital, Tom's River.

OCEANA, a W. co. of Mich., on Lake Michigan, drained by White and Maskegon rivers; area, 780 sq. m.; pop. in 1860, 1,766. It has an undulating surface and a good soil. Capital, Lackeminto.

OCEANIA, or OCEANICA, a name given by geographers to a fifth division of the world, which includes all the islands of the Pacific between Asia, the Indian ocean, the Antarctic ocean, and America. It comprehends the Indian archipelago, Australasia, and Polynesia.

OCEANIDS, in Grecian mythology, a class of nymphs, daughters of Oceanus and Tethys. They were 8,000 in number, and were said to have an equal number of brothers.

OCEANUS, a Grecian divinity, god of the water, which was believed to encircle the whole earth. According to Hesiod, he was the son of Uranus and Gæa (Heaven and Earth), and the eldest of the Titans.

OCELLUS LUCANUS, a Pythagorean philosopher, born in Lucania in Italy, and supposed to have flourished in the 5th century B. C. The works attributed to him were: "On Law," "On Kingly Rule and Piety," and "On the Nature of the Whole," the last of which, originally written in the Doric dialect, is the only one that has come down to us. This treatise, which Tennemann pronounces apocryphal, is divided into 4 chapters, in which he maintains that the whole (*το πᾶν*) has no beginning nor end, and that men have always existed.

The best editions are by A. F. W. Rudolphi (Leipzig, 1801-'8), and Mullach (Berlin, 1846). Ocellus was translated into English by Thomas Taylor in 1831.

OCELOT, an American group of medium-sized cats, of slender and elegant proportions, without tufts to the ears, and with more or less elongated and connected spots diverging in longitudinal rows backward and downward from the shoulders, of a yellowish color bordered with black. The common ocelot (*Felis pardalis*, Linn.) is about 3 feet long to the base of the tail, the latter being about 15 inches additional; the general color is grayish, with large fawn-colored, black-bordered spots forming oblique bands on the flanks; ears black, with a white spot below; chin and throat white, with a black bar beneath the former and another under the neck; 2 black lines on the side of the forehead and 2 behind each eye; under surface white, with irregular black patches; tail above black, with narrow bands of white. Specimens vary much in their markings, in the tinge of the tawny spots, in the chain-like character of the streaks, and in the spots and blotches on the legs. It is found in Brazil and Guiana, and in Mexico, Texas, and the south-western United States. The head is short, the neck long and thin, the body slender, tail moderate, and hair soft and not very thick. It is called leopard and tiger cat in Texas and Mexico, is rather nocturnal in habit, and climbs trees in pursuit of small animals and birds; though active and muscular, it is easily tamed, and is gentle and playful in captivity, unless fed on raw meat exclusively; it is very graceful and quick in its movements, and when pursued takes to a tree; it is seldom seen on the open plains, preferring woods and thickets. From its small size, it is little to be feared by the herdsman; but from the beauty of the skin, which is worth about \$2, it is always killed when an opportunity occurs. In the linked ocelot (*F. catenata*, H. Smith), by many considered a mere variety of the last, the markings are more lengthened, the ground color more reddish, and the body and limbs stouter. The long-tailed ocelot (*F. macroura*, Neuwied) is often grayish tawny yellow, paler below, with irregular unenclosed longitudinal markings on the body; of a total length of 44 inches, the tail forms about 19, and is semi-annulated, black at the tip. Another allied species, inhabiting, like all the above, South America, is the margay (*F. tigrina*, Linn.); it is 18 inches long, with a tail of 8 inches; the color is tawny yellow, with black lines and bands upon the head, neck, and throat; the open spots of the body enclose a reddish centre, and are surrounded by a black line; the limbs are spotted and the tail ringed with black.

OCHRA. See OKRA.

OCHRE, earthy oxide of iron employed with oil as a paint. When obtained as a native product it is intermixed with argillaceous or calcareous earth; and it is also prepared

by the decomposition and oxidation of pyritous ores. Deposits of it are produced about springs that flow from rocky beds which contain iron pyrites in a state of decomposition. The color of the material varies with the degree of oxidation of the iron, and may be changed by heat from yellow to brown and red. The earthy matters present also affect its color, and these may be partially or wholly removed by washing, the heavy sediments remaining behind. For the finer varieties of ochre these sediments are ground in mills. Ochres are sold under a variety of names. The coarser sorts are sometimes known as stone ochres. A kind from the Persian gulf is called Indian red. There are also the Spanish brown, a yellow variety known as the French ochre, the Oxford and Roman ochres of brownish yellow colors, and others distinguished merely by the names of their colors. Dr. Thomson states that the term ochre is applied to native oxides of cerium, molybdenum, lead, tungsten, chromium, and uranium.

OCHTERLONY, SIR DAVID, a British general, born in Boston, Mass., Feb. 12, 1758, died in India, July 15, 1825. At the age of 18 he entered the service of the East India company, became lieutenant in 1778, and rose through the intervening grades to the rank of lieutenant-colonel in 1803. After the conclusion of the Mahratta war of 1803-'4, he was appointed to the command of the fortress of Allahabad, in 1812 was made colonel, and in 1814 major-general. In the Nepaulese war he captured the almost inaccessible fortress of Mallown, and, receiving the chief command, brought the war to a close in March, 1816. For his services he was made knight commander of the bath, was created a baronet, and received from the East India company a pension of £1,000 per annum. In 1817 he also received the thanks of both houses of parliament for his conduct in the Nepaulese war, and, after having served in various other important posts, was appointed in 1822 resident and political agent at Rajpootana.

OOKLEY, SIMON, an English orientalist, born in Exeter in 1678, died in Swavesey, Cambridgeshire, Aug. 9, 1720. He was educated at Queen's college, Cambridge, in 1705 was presented to the vicarage of Swavesey, and in 1711 chosen professor of Arabic in the university of Cambridge. His principal work, compiled from Arabic MSS. in the Bodleian library at Oxford, was a "History of the Saracens" (2 vols. 8vo., 1708-'18). He dates the 2d volume from Cambridge castle, where he was imprisoned for debt. This work has a high reputation, and has been often reprinted. A good edition of it is published in Bohn's "Standard Library" (London, 1848). His other works are: *Introductio ad Linguas Orientales* (1706); "History of the Present Jews throughout the World," translated from the Italian of the Jewish scholar Leo Modena (1707); "The Improvement of Human Reason, exhibited in the Life of Hai

Ebn Yokdhan," from the Arabic (1708); "An Account of South-West Barbary" (1713); and a new translation from the Arabic version of the second "Apocryphal Book of Esdras" (1716).

OOCULGEE, a river of Georgia, about 200 m. long, formed by 3 branches, the South, Yellow, and Ulcofauhachee, which rise in the N. part of the state and unite at the S. corner of Newton co. It flows in a S. S. E. direction till toward its termination, when it sweeps round in a curve to the N. N. E. and joins the Oconee at the S. extremity of Montgomery co., where the two form the Altamaha. It receives the Little Ocmulgee, its principal tributary, about 10 m. from its mouth. It is navigable for steamboats of light draught to Macon, where there is a fall affording great water power.

OOCONEE, a river of Georgia, which rises in Hall co., in the N. E. part of the state, and flows in a S. S. E. direction until its junction with the Ocmulgee to form the Altamaha. Its total length is about 250 m., and it is navigable for small steamers to Milledgeville, 100 m. above its mouth.

O'CONNELL, DANIEL, an Irish orator, politician, and agitator, born at Carhen, near Cahirciveen, county of Kerry, Aug. 6, 1775, died in Genoa, May 15, 1847. He was the eldest son of Morgan O'Connell, a Catholic gentleman whose family was of very ancient and respectable standing in the south of Ireland, and who lived in seclusion on a small estate amid the romantic wilds of Kerry. A poor old hedge schoolmaster named David Malony taught Daniel the alphabet, and at the age of 13 the boy was sent to a school at Redington, Long island, near Cove, or Queenstown as it is now called. Here he remained about a year without giving much indication of superior talents, and in 1791 was sent to the Jesuits' college of St. Omer in France. The principal of this institution wrote of him at the end of a year: "I never was so much mistaken in my life as I shall be, unless he be destined to make a remarkable figure in society." In the following year O'Connell spent a short time at the English college of Douay; but the outbreak of the reign of terror compelling him to leave France, he returned home, and in 1794 entered himself as student of law at Lincoln's Inn, the penal laws against Catholics having been somewhat modified during his absence, and the legal profession having been thrown open to persons of that creed. Four years afterward he was called to the bar, and soon became distinguished as a brilliant and successful advocate. He kept aloof from politics at this time, and had no sympathy with the violent revolutionary spirit of the period, which in fact throughout his life he opposed, in accordance with his well known saying that "he would accept of no social amelioration at the cost of a single drop of blood." His first political speech was made at Dublin, Jan. 13, 1800, at a meeting of Catholics held to petition against the proposed

legislative union between Great Britain and Ireland; the meeting was broken up by the intervention of the military. From this period dates the commencement of his career as a public agitator. In 1802 he married his cousin Mary, daughter of Dr. O'Connell of Tralee, and in a few years was in good practice and had gained a high reputation as a barrister. He now became gradually absorbed in politics, and was soon the acknowledged leader of political reform in Ireland. He devoted himself with surprising force and energy to the Catholic question as it was called, that is to say, the question of the claims of the Roman Catholics of Ireland to political equality with Protestants. Alluding to this period of his life in a pamphlet published in 1842, he says: "For more than 20 years before emancipation, the burden of the cause was thrown upon me. I had to arrange the meetings, to prepare the resolutions, to furnish replies to the correspondence, to examine the case of each person complaining of practical grievances, to rouse the torpid, to animate the lukewarm, to control the violent and the inflammatory, to avoid the shoals and breakers of the law, to guard against multiplied treachery, and at all times to oppose at every peril the powerful and multitudinous enemies of the cause. At that period, and for more than 20 years, there was no day that I did not devote from one to two hours, often much more, to the working out of the Catholic cause, and that without receiving or allowing the offer of any remuneration, even for the personal expenditure incurred in the agitation of the cause itself." In 1815 Mr. O'Connell, having in one of his speeches applied the term "beggarly" to the corporation of Dublin, was challenged by Mr. D'Esterre, a member of the city government. A duel ensued, and D'Esterre received a wound of which he ultimately died. For this event he ever afterward expressed the deepest sorrow, and never again accepted or offered a challenge. In 1828 the agitation of the Roman Catholic emancipation bill reached its greatest height under the direction of the Catholic association. In June of that year Mr. O'Connell became a candidate for the representation of the county of Clare in parliament, and was elected by a large majority. On proceeding to take his seat, he refused as a Roman Catholic to take the test oaths which had been framed for the express purpose of excluding those who held his faith. His firm attitude on this point commanded general attention, and led to protracted and animated discussions both in parliament and before the people. The agitation in Ireland, under his skilful guidance, rose to such a formidable height that at length the great leaders of the conservative and Protestant party, Sir Robert Peel and the duke of Wellington, became alarmed and resolved to concede emancipation to the Catholics. Parliament met Feb. 6, 1829; the speech from the throne recommended a final, equitable, and satisfactory adjustment of the Catholic claims; in the

course of the session the last of the civil disabilities to which the Catholics had been so long subject were repealed; and in May Mr. O'Connell took his seat as a member of parliament. He was received by the house with marked coldness, and was both disliked and feared. In the course of time, however, he commanded the respect and admiration of his audience, and became one of the most attractive of parliamentary orators. In 1880 he declined the representation for Clare, and was elected by his native county of Kerry. Subsequently he represented Dublin from 1882 to June, 1885, and again in 1887. In the latter part of 1885 he was elected for Kilkenny, and in 1841 for the county of Cork, and in the same year lord mayor of Dublin. To keep alive the spirit and activity of his followers, which seemed likely to subside with the removal of the Catholic grievances, O'Connell proclaimed during his first year in parliament, that a repeal of the legislative union between Great Britain and Ireland was the only means of obtaining justice for the latter kingdom. Though he steadfastly maintained this position for the rest of his life, he does not seem to have had any expectation that the repeal would ever be effected, but used the agitation of it as a weapon with which to menace the English government and coerce it into measures of amelioration. To compensate him for the loss of income he had suffered by relinquishing his practice as a lawyer, and to reward his public services, an annual subscription was organized among the Irish people, under the denomination of "rent," and paid to Mr. O'Connell, a proceeding which involved him in much obloquy. In 1842 and 1843 immense gatherings, or monster meetings as they were called, were held by the repealers on the royal hill of Tara, the Curragh of Kildare, the Rath of Mullaghmast, and other places renowned in Irish history and in the songs and traditions of the people. Some of these assemblages were estimated at 500,000 persons, and nothing was spared to make them imposing in appearance as well as in numbers. The liberator, as O'Connell was now familiarly called, appeared at them, making speeches of the most violent and exciting character, but taking extreme care in action to keep his followers within the bounds of law. At length he called a monster meeting at Clontarf near Dublin on Sunday, Oct. 8, 1843; and the preparations for it, including a body of "repeal cavalry," had such a military air that the government thought it time to interfere. On Oct. 7 a proclamation was issued declaring the public peace to be endangered by these meetings, and warning all persons to keep away from Clontarf. O'Connell, who with all his violence of language was ever anxious to keep the peace, countermanded the meeting, and the people generally stayed away. On Oct. 14 he was arrested by order of the government, together with his son and 8 of his coadjutors, on charges of conspiracy,

sedition, and unlawful assembling. They were tried in the following February, and found guilty. O'Connell was sentenced to imprisonment for 12 months and to pay a fine of £2,000, and was bound over to keep the peace for 7 years. An appeal was made to the house of lords, and the decision of the Irish judges was reversed. This trial, however, gave a death-blow to the repeal association and the repeal movement, though for a while the monster meetings continued and the agitation for repeal was actively kept up. But very soon dissensions broke out between O'Connell and some of his associates who formed the party of "Young Ireland," who scoffed at his renunciation of physical force in seeking political reforms and were impatient for insurrection and war. A severe blow was struck at him in 1845, when it was shown by a thorough and careful investigation that, while holding forth against oppression in public, and drawing from the contributions of the peasantry a princely income on the ground of his exertions in behalf of their freedom and prosperity, he was himself a middleman, holding land on low leases from the landlord, and gaining profits out of a tenantry in "a lost, wretched, and neglected condition." He was furious at the exposure, but the facts were proved against him. He grew anxious and feeble and at length ill, and had to abandon political agitation altogether, to which indeed the famine now creeping over Ireland put a sudden stop. The distress of his country painfully augmented his own sufferings, and at length his physicians directed that newspapers should be kept from him and no one admitted to his presence who would speak of Ireland. Early in 1847 he set out on a pilgrimage to Rome, hoping to die at the holy city and under the blessing of the pope. But he sank too rapidly for this. He was carried to Paris and Marseilles, and lastly to Genoa, where he died. At his own request his heart was embalmed and carried to Rome, and his body taken back to Ireland, where it received a magnificent funeral.—Alison, the tory historian, who was once examined for 8 hours by Mr. O'Connell before a committee of the house of commons, thus describes his person and character: "In appearance he was striking; he would have been remarked among a thousand. His countenance was neither handsome nor commanding, but it had something in it which irresistibly attracted the attention. Strong and square-built, his figure conveyed the idea of great personal strength; quick, but evasive, his eye gave the impression of Jesuitical cunning. He scarce ever looked you in the face. In manners he was, when he chose, extremely pleasing; none could exhibit when he desired it more courtesy, or was a more agreeable companion; and none, when otherwise inclined, could let fly a more fearful volley of vulgar abuse. . . . He belonged to the age of Ignatius Loyola or St. Francis rather than that of the French revolu-

tion. Pope Hildebrand was not more devoted to the interests of the holy see; Peter the Hermit did not possess in a higher degree the art of rousing and violently moving the great body of the people. His abilities were of a very high order—no man does such things without great powers; but they were not of a cast superior to his achievements. *Par negotiis, non supra*, was his true characteristic. He was born an agitator, and there he was supreme; but he was neither more nor less. He had remarkable talents, but no genius, and still less taste or refinement. To great powers of oratory he united a marvellous faculty for moving the multitude. . . . With equal facility he addressed the house of commons in a powerful legal argument, and harangued the electors of Clare in strains of disgraceful ribaldry; with equal truth he in the same breath called the Irish 'the finest peasantry upon earth,' and heaped opprobrium upon the 'stunted corporal' who had delivered Europe, and the 'bigot Peel' who had endangered his own fame to strike the fetters of religious intolerance in Europe."—See the "Life and Speeches of Daniel O'Connell," by his son John O'Connell, M. P. (2 vols., London, 1846).

O'CONNOR, ARTHUR, a leader in the Irish rebellion of 1798, born in 1763, died near Nemours, France, April 25, 1852. He was admitted to the bar in 1788, became a member of the Irish parliament, and made a speech in favor of Catholic emancipation, which so offended his uncle, Lord Longueville, that he disinherited him. Subsequently joining the united Irishmen, he became one of their directory of five, and in 1796 was arrested on a charge of high treason, but was finally discharged. Having gone to France, he was arrested again on his return, tried, and acquitted; but being held in detention he escaped, and took up his residence in France. In 1804 he was created by Napoleon lieutenant-general, and subsequently general of division. About 1809 he married the daughter of the philosopher Condorcet, whose works he is said to have edited. He published "Letters to the Earl of Carlisle, in reply to Earl Fitzwilliam's two Letters on the State of Ireland" (1795); "Letters to Earl Camden" (1798); "The Present State of Great Britain" (1804); and, under the assumed name of Condorcet O'Connor, a volume against the Bourbons and monarchy in general (1830).

O'CONNOR, FEARGUS EDWARD, a leader of the chartists in England, born at Dangan Castle, co. Meath, Ireland, in 1796, died at Notting Hill, near London, Aug. 30, 1855. Early attaching himself to the radical party, he was in 1832 returned to parliament by the county of Cork. Re-elected in 1835, he was unseated on the ground of disqualification, and from that time agitated the rights of the lower classes so constantly, in public addresses and in his journal called the "Northern Star," that he came to be regarded as the head of the chartist party, and in 1847 was elected by it to parlia-

ment from Nottingham. The failure of his efforts (see *OBARTISM*) produced an unsettled state of mind; and during a visit to America, insanity became clearly developed. While still a member of parliament, he was taken to a lunatic asylum at Chiswick, and there remained till within a few days of his death, a jury finding, on an application for a commission of lunacy in 1853, that he had been of unsound mind on and since Jan. 16, 1852. His funeral was attended by an immense concourse of his admirers.

OCONTO, a N. E. co. of Wis., bounded N. E. by Michigan, from which it is separated mostly by the Menomonee river, and S. E. by Green bay; area, 2,268 sq. m.; pop. in 1855, 1,501. It is drained by the Oconto, Pishtego, Wolf, and other rivers, and is covered with pine forests. Capital, Jones's Mill.—The Oconto river rises in the N. E. part of the state, and flowing first southward and then eastward, falls into Green bay.

OCCOSINGO, a town in the Mexican state of Chiapas, 65 m. S. E. from Ciudad Real; pop. 4,000. It derives its principal interest from a series of extraordinary aboriginal monuments in its vicinity, which closely resemble those of Palenque, with which they seem to have been contemporaneous. They have been in part described by Mr. Stephens in his "Incidents of Travel in Central America," and by Capt. Dupaix in his report to the Spanish crown on the antiquities of Mexico.

OCTAVE. See *MUSIO*.

OCTAVIA, the sister of the emperor Augustus, and wife of Mark Antony, died in 11 B. C. She was married to Claudius Marcellus, from whom Julius Cæsar was anxious to have her divorced in order that she might be united to Pompey; but as the latter declined the proposition, she continued to live quietly with her husband until his death in 41 B. C. The alliance between Octavius and Antony was now strengthened by the marriage of Octavia to the latter. She accompanied her husband in his eastern expedition, and by her mediation effected a reconciliation between him and her brother in 36, when the prospect of an open rupture was imminent. Antony, now undertaking an expedition against the Parthians, fell again under the influence of Cleopatra; and when in 35 Octavia went to the East with reinforcements of men and money, he accepted the aid, but refused to meet her, requesting her to return after she had come so far as Athens. She would not, however, on her arrival home, take any part against her husband, but remained at his house and educated his children; yet in 32 Antony requited her conduct by sending her a bill of divorce. After his death, in spite of the wrongs received from him, she brought up his children by Fulvia, and even those by Cleopatra. Octavia had 5 children, 3 by Marcellus and 2 daughters by Antony; from the two latter were descended the emperors Caligula, Claudius, and Nero. She was pos-

sessed of great accomplishments, was virtuous in an age of licentiousness, and was universally considered the superior of Cleopatra in beauty. Augustus erected an important public building between the circus Flaminius and the theatre of Marcellus, which he named in honor of his sister Porticus Octavia.

OCTAVIUS. See *AUGUSTUS*.

OCTOBER (Lat. *octo*, eight), the 10th month of the year. In the Roman calendar it was originally the 8th month, whence its name, which it retained after the beginning of the year had been changed from March to January. In the Roman mythology October was sacred to Mars.

OD (Sanskrit *ea*, to blow; whence the old German *woodan*, all-pervading, *Odin*, the omniscient deity; and thus *od*, the all-pervading force), a supposed universal force of nature, which Baron Karl von Reichenbach claims to have discovered in the course of investigations commenced in 1844, but which is not recognized by scientific men generally as entitled to a place in established science. Without undertaking to discuss the subject, we shall place ourselves on Reichenbach's standpoint while describing his theory. *Od*, according to him, pervades all nature, and is akin to the great physical forces of electricity, magnetism, chemical affinity, heat, light, &c., and always accompanies them, so that wherever they are in action *od* is developed, and the strength of its most active development is often in proportion to the energy of their action. In living animals, in effervescing and fermenting liquids, in putrefying substances, in magnets, and in galvanic batteries, *od* is briskly generated. It radiates from the generators, and its rays pass through all kinds of matter, at a speed of about 100 feet per minute, slower than light and more rapid than heat. As in electricity and magnetism there is a polar dualism, so also there is in *od*; it has two poles, the positive and negative, which keep company respectively with the electric and magnetic positive and negative poles. These odic poles appear in all organic substances. The human body is *od*-positive on the left side and *od*-negative on the right. Amorphous substances are unipolar taken singly, but taken collectively they show an odic dualism, those having the strongest affinity for oxygen being *od*-negative, and oxygen and the substances having the least affinity for it being *od*-positive. This gradation of amorphous bodies from *od*-negative to *od*-positive is called the *od*-chemical order, and is found to correspond with the electro-chemical order established by Berzelius. The odic radiation can be felt and seen by certain persons called sensitives, who have a peculiar nervous susceptibility; while the majority of mankind, called non-sensitives, are entirely insensible to the odic influences and impressions. Odic sensitiveness has many symptoms, among which are liability to somnambulism, capability of being magnetized, inability to sleep on the left

side in the northern hemisphere, dislike of strong yellow colors, fondness for blue as opposed to yellow, dislike of crowds and close rooms, and dislike of fatty and fondness for sourish victuals. The meeting of like odic poles causes a disagreeable sensation to the sensitive, while an agreeable sensation follows the pairing of unlike poles. The points of quartz crystals and the north poles of magnets send out strong emanations of positive od, and cause a cool and agreeable feeling to the sensitive left hand; while the base of the crystal and the south pole of the magnet, being od-negative, cause a lukewarm and disagreeable sensation to that hand. The sensations caused by these opposite poles are the reverse on the positive right hand. The odic emanation is felt by the touch as though it were a breath; and it is also seen in the dark by the sensitive, but not in the light. The odic rays are perceived like a luminous vapor, and substances which generate od glow with their own od-light, and appear as if incandescent or semi-transparent. The od-light, like solar light, has a spectrum; the rays of positive od are blue, those of negative od yellow. These different colors are seen by sensitives in the odic emanations from the opposite poles of crystals, magnets, the human body, &c. The earth is strongly odic, being od-negative in the northern hemisphere, and od-positive in the southern. If a strong bar magnet be set upright, a stream of od will arise from it, and be distinctly visible in the dark to sensitives. If a circular iron plate be fastened horizontally on top of the bar, an odic rainbow will encircle the plate, caused by the radiation of the odic light from its circumference. The color will be blue in the north; green in the north-west; yellowish green in the west; yellow, orange, and red in the south; grayish red and gray in the east, changing again to blue in the north. The causes of many singular phenomena not hitherto understood are explained by the odic theory. The reason why many persons cannot sleep on their left sides (in the northern hemisphere) is because the northern pole of the earth, being od-negative, causes a disagreeable feeling to the od-negative left side. Similar influences govern the occasional dislike of yellow and fondness for blue. The discomfort caused by the proximity of a person looking over our shoulders arises from the pairing of like poles. The ghosts seen in grave yards are the odic emanations arising from putrefying corpses on fresh graves, and seen at night by sensitives. Motion of all kinds develops od, and the flowing of water underground may by that means be felt by sensitives; and here is the secret of the water finders, whose divining rod, whether consciously or unconsciously, moves only when the odic influence of the flowing water is felt in the sensitives' feet and legs. Od is the agent or force by which mesmerism or animal magnetism operates; and all the mesmeric phenomena belong within the domain

of od. Od is a universal force. Mesmerism is only its application to influence the animal frame in a peculiar way. Among the most important phenomena of odic influence as exerted on the human body are somnambulism and cramp, which are two opposite states of the nervous system, the former being entirely and the latter chiefly confined to sensitive persons. Somnambulism is an od-negative state; cramp, od-positive. In high sensitives the former can be created by a few downward passes of the hand over the whole length of the body; the latter by a few upward passes. —Such are the main phenomena of od as set forth in Reichenbach's works, the chief of which are "The Dynamics of Magnetism" (translated into English by Dr. Ashburner), "The Odic-Magnetic Letters," and "The Sensitive Man and his Relation to Od."

ODD FELLOWS, INDEPENDENT ORDER OF, a secret charitable society existing chiefly in Great Britain and the United States. The origin of this association has been ascribed by some writers to very remote periods and celebrated personages. According to one account, it was known among the Goths, Huns, and other northern nations in the 4th century; was established in Spain in the 5th century, in Portugal in the 6th, and in France in the 12th; and was carried from France to England by John De Neville and other knights, who formed there a "loyal grand lodge of honor," which in the 16th century was changed into the order of odd fellows. Other writers, yet more fanciful, ascribe its origin to the Roman soldiers in the time of Nero, and its name to the emperor Titus, who is alleged to have called them odd fellows from their singularity. Still another class of writers, anxious to make sure of the greatest possible antiquity, ascribe the origin of the order to Adam; and an emblem procured from an English lodge in 1828, now in possession of the grand lodge of the United States, represents the father of mankind in the act of laying the foundations of a lodge. These fables, however, have been totally discarded of late years by the authorities of the order, and have been pronounced absurd by the grand lodge of the United States. Its true history is the following. In the latter part of the 18th century lodges or societies of mechanics and laborers existed in London, calling themselves "Ancient and Honorable Loyal Odd Fellows." Their meetings were for convivial purposes, and were generally held in taverns. It became the custom for each member once a week to contribute a penny to form a fund for the relief of the poor among them, and especially to defray burial expenses, and to provide for widows and orphans. In 1788 James Montgomery wrote for a London lodge of this sort a song still current in the lodges of the order, beginning:

Where friendship, love, and truth abound
Among a band of brothers.

On the extension of the order to Liverpool the lodges united in a general system under the

title of the "Union Order of Odd Fellows," having London as its seat of government. The institution rapidly spread to other English cities, and in 1809 attempts were made to reform it and to abolish its convivial character. This innovation was opposed by the majority, and in 1818 a convention of the friends of reform was held at Manchester, when several lodges seceded from the union order and formed the "Independent Order of Odd Fellows." In 1825 a central standing committee was established in Manchester to govern the order in the interim between the sessions of the grand lodge or national movable committee, as it is termed. Dissensions arose which led to secessions, but the "Manchester Unity" remains to this day the main body of British odd fellows, and numbers about 500,000 members in its lodges. Odd fellowship in the United States owes its introduction to Thomas Wildey, an Englishman, a blacksmith by trade, who with 4 others instituted at Baltimore, April 26, 1819, Washington lodge No. 1, which soon afterward procured a charter from the Manchester unity as the grand lodge of Maryland and of the United States.—The organization of the order bears a general resemblance to that of the free masons. The primary body is the subordinate lodge, which derives its power from a charter granted by the grand lodge, and must comprise at least 5 members, who must be males of 21 years, of age or upward. *They make their own laws and manage their own pecuniary affairs, require dues from their members to the amount generally of from \$4 to \$10 a year, pay to the sick a weekly allowance, and assign a stated sum for the burial expenses of a member or a member's wife. A member may withdraw at any time on application, and by paying up all arrearages, either to unite with any other lodge, or entirely from the order. In due season after initiation he may apply for and receive certificates entitling him to receive the first 5 degrees of the order by paying certain sums. These degrees, in the order in which they are given, are termed: 1, the white degree; 2, the covenant degree; 3, the royal blue degree; 4, the remembrance degree; 5, the scarlet degree. There is beside the degree of Rebekah, or ladies' degree, which was instituted by the grand lodge of the United States in Sept. 1851, and is conferred on members of the scarlet degree and on their wives. The officers of a subordinate lodge are the noble grand, who presides, the vice grand, the treasurer, and the permanent and recording secretaries. The treasurer and the permanent secretaries are elected annually, the others for 6 months. A person who has filled the office of noble grand for 6 months is thereafter styled past grand, and a special degree exists to which they alone are eligible. The grand lodge of a state is formed of past grands not fewer than 5 in number. The grand lodge derives a revenue from fees for charters, dispensations, and a percentage on the revenues of subordinate lodges. Its presid-

ing officer is the grand master, who is elected annually. The grand lodge of the United States is composed of representatives elected biennially by the state grand lodges. Its presiding officer is the grand sire, who must also be a past grand master of a state lodge.—There is also within these lodges a separate institution called the grand encampment, whose members are termed patriarchs. Those only are eligible who have received the scarlet degree in the subordinate lodges. Superior to the encampments there is in each state a grand encampment. The elective officers of an encampment are a chief patriarch, who presides, a high priest, a senior warden, a scribe, a treasurer, and a junior warden. Grand encampments are composed of all past chief patriarchs in their jurisdiction, and in some states also of past high priests. The officers of a grand encampment are the most worthy grand patriarch, most excellent grand high priest, right worthy grand senior warden, right worthy grand junior warden, grand scribe, grand treasurer, and grand representative.—In 1860, according to the official returns, there were in the United States 8,548 lodges and 178,818 members. The amount paid for relief in that year was \$548,746.95, and for other charitable purposes \$72,450.95; and the total amount for 80 years is \$8,478,528.41.

ODE (Gr. ὁδῷ, a song), a lyrical poem of an elevated character, composed under circumstances of mental excitement, poetic exaltation, or other intellectual emotion. The Greeks called every short poem intended to be sung or accompanied by instruments an ode. Of antique odes, those of Pindar, Anacreon, and Horace have afforded the most prominent models to modern writers; and the Pindaric ode has proved the parent of countless varieties of so called irregular odes, on the supposition that the Greeks admitted an absolute license of metre in poems of this description. The odes of Pindar, however, as well as the elaborate choruses of the Greek dramatists, are constructed on a scheme of metrical regularity, not less perfect than that discernible in the fragments of Alcæus, Simonides, and Sappho, and the odes of Anacreon and Horace.

ODENSE, a seaport town of Denmark, capital of the island of Fünen, situated on a small river which falls into a bay of the same name about a mile from the town, 86 m. W. S. W. from Copenhagen; pop. in 1861, 11,122. It is a prosperous trading town, and one of the oldest places in Denmark. Its cathedral, founded in 1080, and completed in 1801, contains the tombs of several Danish kings. The town has breweries, distilleries, founderies, and woollen mills. It is said to have been founded by Odin, whose grave is pointed out in a place $\frac{1}{2}$ of a mile N. of the town.

ODENWALD, a mountain region of Germany in Hesse-Darmstadt, lying between the river Neckar, which separates it from the Schwarzwald, and the Main, which separates

it from Spessart. It includes the sources of various small tributaries of the Rhine, Neckar, and Main. The Bergstrasse, or mountain road, on which are the towns of Langen, Darmstadt, and Bensheim, passes along its W. border; and in various parts of the district there are many interesting ruins of the Roman period. The highest mountain of the Odenwald is the Katzenbuckel, which rises to the height of 2,800 feet above the sea, and among the other summits are Felsberg, Malchen, Oelberg, and Kaiserstuhl.

ODEON (Gr. *oideon*), a species of public building used by the ancient Greeks and Romans for contests in vocal and instrumental music, and occasionally for other purposes, such as philosophical disputations, or the administration of justice. In its general plan it was not unlike the theatre, and in some instances it served as a place of rehearsal for the choruses, previous to their public performances in the theatre. Hence it was smaller than the latter building, and was roofed over for the purpose of retaining the sound. The earliest structure of the kind was that erected by Pericles at the base of the S. E. part of the acropolis in Athens, and in the immediate vicinity of the great theatre. It was burned at the capture of the city by Sylla, and restored by Ariobarzanes II., king of Cappadocia. Athens contained two other odeons, one of which has sometimes been confounded with the Pnyx; the other, a magnificent building, capable of containing 8,000 persons, was erected by Herodes Atticus under the S. W. part of the acropolis, where its ruins are still visible. Corinth, Messene, Smyrna, and many other cities of Greece and its colonies also possessed buildings of this class, some of which were little inferior in extent and grandeur to those of Athens. The first odeon in Rome was built by Domitian, and his example seems to have been occasionally followed there and in other parts of Italy. In modern times the term odeon is sometimes applied to buildings devoted to dramatic or lyrical performances, or to purely musical entertainments, as the odeon in Paris, and that in Munich, which is used as a concert room.

ODER (anc. *Viadrus*), a river of Germany, rising in Moravia, about 14 m. E. N. E. from Olmütz, 990 feet above the level of the sea, and flowing through Prussian Silesia and Brandenburg in a tortuous but generally N. W. course to Oderberg, where it changes its direction to N. E. and flows through Pomerania and the Grosses Haff into the Baltic. Its whole course is about 550 m., and it is navigable for about 400 m. to Breslau for vessels of 50 tons, and for smaller craft to Ratibor, about 100 m. further. The chief tributaries from the right are the Malapane, Bartsch, and Wartha, and from the left the Oppa, Silesian Neisse, Weitritz, Katzbach, Bober, and Bohemian Neisse. The chief towns on its banks are Ratibor, Kosel, Oppeln, Brieg, Breslau, Glogau, Frankfort, Küstrin, and Stettin. It is connected by canals with the Elbe and the Vistula.

ODESCALCHI, the name of a noble family of Rome, the most distinguished of whom are the following. I. BENEDETTO. (See INNOCENT XI.) II. MARCO ANTONIO, cousin of the preceding, born in Como about 1620, died in Rome in 1670. He entered the priesthood, and after his cousin's promotion went to Rome to reside; but he refused all honors and preferments, and devoted himself to works of charity. Observing that, though there were so many hospitals in Rome, destitute strangers were obliged to pass the night in the porches of the churches and under the porticoes of the palaces, he turned his own house into a hospital in 1656, and received there the poor and the destitute of all nations. He subsequently bought some adjacent houses, and enlarged his hospital, until it contained 1,000 beds. He frequently went through the city in the evening in search of the houseless, whom he conveyed to this hospital. At his death he bequeathed all his property to it, and Innocent XI. not long afterward enlarged it to the capacity of 3,000 beds. It is now known as the hospital of St. Gallus. III. TOMMASO, a kinsman of the preceding, died in 1692. Having been appointed almoner of Innocent XI., he sought opportunities to do good with his own revenues, as well as with those of the pope. Among the poor and destitute, who were congregated at the hospital of St. Gallus, were many children for whom he determined to erect an asylum, where they might be taught to read, and learn some trade or employment. He began with 88 children, and through the liberality of the pope the number was soon increased to 70, most of them street boys and runaways. In 1686 he laid the foundation of a large hospital, which he named San Michele, to be occupied solely by vagrant boys, and those who were in the way of temptation. In this hospital they were to be educated and taught the weaver's trade. At his death he left considerable funds for its further endowment. In 1696 an almshouse founded in 1580, and an orphan asylum founded in 1582, were united with this establishment by Innocent XII., and there were added to it in 1703 a reformatory for boys convicted of crimes, in 1785 a female penitents' refuge, and in 1790 an asylum for young girls exposed to danger from the loss of parents or guardians.—The character of the family seems not to have been changed by the lapse of years, for in 1816 an industrial school for poor girls above 12 years of age, called the conservatory of the Virgin of Sorrow, was founded at Rome by a Cardinal Odescalchi.

ODESSA, a city and seaport of European Russia, in the government of Cherson, on the shore of a bay in the N. W. part of the Black sea, between the mouths of the rivers Dniester and Dnieper, 90 m. W. S. W. from Cherson, about 800 m. S. W. from Moscow, and 390 m. N. from Constantinople; lat. 46° 29' N., long. 30° 44' E.; pop. in 1857, 107,370. It stands upon a broad plateau about 80 feet above the sea, to which it descends almost

perpendicularly; and the town communicates with the beach by a wide stairway composed of 200 steps. In the rear the plateau spreads out into vast steppes almost destitute of vegetation, from which in summer dense clouds of dust are blown. The streets are wide and laid out at right angles, and there are several squares well planted with trees; but the streets are macadamized and not paved, and are covered with either dust or mud. The town is enclosed by a wall, and is defended by a fort at the S. E. extremity, and by several batteries along the shore; and the ground between the town and the harbor is occupied by a row of barracks. The roadstead is exposed to E. winds, but the anchorage is good, and an inner harbor capable of accommodating 300 vessels at the quays has been formed by 2 moles. The boulevard, running along the shore, is lined with many handsome edifices, and ornamented by several monuments, the most remarkable of which is a bronze statue of the duke of Richelieu, a French *émigré* who entered the service of the czar and was governor from 1803 to 1814, and materially improved the appearance and commercial prosperity of the town. The principal buildings are the cathedral and other churches, government house, admiralty, custom house, hospital, exchange, museum, opera house, and theatre. The houses are generally well built of soft calcareous stone. There are numerous schools, a college, 2 public and several circulating libraries, a botanical garden, and a museum for South Russian antiquities founded in 1825. The climate is generally considered healthy. The heat in summer, however, is very great, and in winter the port is generally closed by ice for about 2 months. Good water is exceedingly scarce, the surrounding country, with the exception of a narrow belt along the shore, being an arid steppe. The town is supplied from extensive reservoirs with water conveyed by an aqueduct about 20 m., artesian wells having been sunk 600 feet without success. There are but few manufactures, but Odessa is for most things a free port, and a very extensive trade is carried on. The soil of the districts bordering the steppes in the interior, particularly on the N. side, is exceedingly productive, and yields large crops of grain, especially wheat, which is for the most part exported through Odessa to the ports of the Mediterranean and Great Britain. In the year ending Sept. 30, 1859, there were exported 6,697,765 bushels of wheat, 1,935,981 of maize, 2,056,288 of rye, 3,371,338 of oats, 2,969,851 of barley, and 1,070,000 of linseed, beside considerable quantities of peas, beans, and rape seed, 47,060 cwt. of tallow, and 67,683 cwt. of wool. During the same period the value of the imports amounted to \$10,397,061, the principal items of which were manufactured goods, porter, oil, fruit, and machinery. The number of sailing vessels that arrived was 1,376, most of which were under the Austrian flag, and next in succession the British,

Sardinian, and Greek. Steamers ply from Odessa to the ports on the Danube and in the Crimea, Oherson, Constantinople, and England. The inhabitants are of mixed races, and consist chiefly of Russians, Greeks, Jews, and Germans; and the commerce is chiefly in the hands of Italians, English, French, and Armenians.—The origin of Odessa is of very modern date. In 1792 Catharine II. selected the site, which was then only occupied by a few houses, and called Khodja-bey. She changed the name to Odessus, which has since been Italianized into Odessa. The town was founded in 1794, and several regiments were employed in constructing public works, so that in the course of a few years considerable progress was made. Alexander I. continued the work, and reduced the import and export duties. In 1817 the port was opened, and the inhabitants declared free from taxes for 30 years. In consequence of the fort of Odessa having fired upon a British steamer under a flag of truce during the Crimean war, a French and English squadron bombarded the place on April 22, 1854; but the fire was directed chiefly against the batteries and the vessels in the harbor. In the following month the British steam frigate Tiger ran aground in the night during a fog, and was fired on by the Russians, and the crew made prisoners. The railroad which connects St. Petersburg with Moscow is to be continued to Odessa.

ODEVAERE, JOSEPHUS DIONYSIUS, a Flemish painter, born in Bruges, Oct. 2, 1778, died in Brussels in Feb. 1830. He studied painting in the academy of Bruges, and subsequently under Suvée and David in Paris. In 1804 he obtained the great prize of the French academy of painting for a picture of the death of Phocion, with a pension to study at Rome, whither he went in 1805, and remained about 7 years. In 1814 he settled in Brussels, where he passed the remainder of his life. His "Peace of Utrecht" and "Battle of Waterloo" brought him into considerable popularity; and the latter picture, with others of his works, was exhibited in many of the Netherlandish provinces during 1817 and 1818. About this time he acted as commissioner on the part of the Netherlands to recover the paintings taken from the national collections to Paris. Some of his pictures are of great size. He was esteemed the best modern Flemish painter of history.

ODILON BARROT. See BARROT.

ODIN, or WODIN, the principal deity of Scandinavian mythology. He was worshipped throughout the north of Europe as the creator and preserver of the world, and the god of war. He is known in the sagas by more than 100 titles, derived from his various attributes and from the countries in which he was acknowledged. He is represented with a raven upon each of his shoulders, the one Hugin (Mind), and the other Munnin (Memory), who whispered into either ear all they had seen and heard in their flight around the world. His wife, Frigga, was next in rank among the

Scandinavian deities; and among their children Thor and Baldur were of most importance and interest.

ODIN, a legendary Asiatic chieftain, the supposed archetype of the Scandinavian god of the same name. According to tradition, he flourished in the 1st century B. C., and was an ally of Mithridates the Great in the war against Pompey. He was driven by the Roman conqueror from his territory upon the Caspian sea to the north of Germany, where he began his conquests and founded his religion. He passed next into the Cimbric peninsula, overran the whole of modern Denmark, and built a city bearing his name (Odense) in the island of Fünen. Other regions of the Baltic came in turn under his sway, and he was soon the recognized monarch of the North. He established himself in Sweden, and built his capital Sigtuna on Lake Maelar, near Stockholm. Ruins of temples are still to be traced in this interesting old town, which bears one of the many titles (Sigge) of the founder. After he had reigned many years, perceiving the approach of death, he summoned his warriors, and informed them that it was his purpose to return to Scythia to be present at the banquet offered him by other gods. So saying, he inflicted upon his breast 9 wounds in the form of a circle, and left orders that the body, which he should leave to them in Sweden, should be burned. This great Scandinavian myth has left impressions in the north of Europe, which time and all the civilization of Christianity have not been able to efface. At the present day, in many districts, whenever unusual sounds are heard in the night, the peasants will say Odin walks there. They call the wintry sighing of the forest the wild hunt of Odin. "Go to Odin" is a common malediction. The hero was especially venerated as the inventor of runes. His armies are supposed to have been the Suiones of Tacitus, and the nations whom he found in possession of Sweden were the tribes of Goths, who had in like manner previously overrun the country. —Several other Odins of later date are mentioned in Scandinavian tradition.

ODOACER, commonly called king of the Heruli, and the conqueror of Italy, put to death, A. D. 493. He was the son of Edecon, a minister of Attila and chief of a tribe of Scyrr. Odoacer led a wandering life in Pannonia and Noricum, and then went to Italy, where he entered the service of the western empire, and speedily rose to high command. After the abdication of Nepos, and the elevation to the imperial throne of Romulus, called in derision Augustulus, the barbarians demanded as a reward for their services the third part of the lands of Italy. When this was refused, the soldiers chose Odoacer for their leader, who drove Orestes, the father of Augustulus, to Pavia, stormed that city, and compelled Augustulus to abdicate his crown (476). By this act an end was put to the western empire, inasmuch as Odoacer, though

styled king of Italy, never assumed the purple or the titles of Cæsar and Augustus, and had no coins struck in his name. But, possessing the supreme authority, he ruled the country mildly, enforced the laws, and protected the frontiers from the barbarians of Gaul and Germany. Although an Arian, he did not molest the church. The Roman possessions beyond the Alps, to the Rhine and the ocean, he ceded to Euric, king of the Visigoths. Crossing the Adriatic, he subdued the province of Dalmatia; crossing the Alps, he defeated Fava, the king of the Rugians, and brought him and a vast number of captives to Italy. At length Theodoric, leader of the Ostrogoths, descended from the Julian Alps, and defeated Odoacer near Aquileia, took Verona, and defeated a second army encamped on the banks of the Adige. Odoacer retired to Ravenna, and for 8 years held out against his rival, but finally capitulated on condition of ruling with equal authority with Theodoric over Italy. Only a few days had passed, however, when Odoacer was killed by the order of his associate, and his troops massacred.

ODOMETER (Gr. *odos*, a road, and *μετρον*, a measure), an instrument for determining the distances passed over in travelling, also known as pedometer, perambulator, &c. It is made in various forms, adapted either for the use of pedestrians or to be attached to wheels specially constructed for this purpose, or to the wheels of carriages. Odometers of the latter class were employed by the ancient Romans, as appears from the mention made of one adapted for a carriage by Vitruvius in his 10th book. In the 15th century they were in use in Europe, and the first attempt made in France to measure a degree of the meridian was by running one of these instruments over the road between Paris and Amiens. (See EARTH.) The principle upon which this kind of odometer is constructed is the recording by a mechanical contrivance the number of revolutions of a wheel (it may be one of those belonging to the carriage) in passing from one place to another. By multiplying this number by the number of feet and inches that make the circumference of the wheel, the distance is at once given. The apparatus for recording the revolutions is a simple train of wheels and index connected with the axle of the wheel, and placed in view of the person in the carriage. Such an instrument should give tolerably correct results upon level roads; but where the surface is very uneven, the actual distance must be much increased by the ascent and descent of the slopes. On account of the facility and rapidity of its work, it is much employed in the surveys of counties and towns, where extreme accuracy is not important, and upon the U. S. coast survey it is also used for filling up the details of roads, &c. In one form it is a wheel of 2 feet $7\frac{1}{4}$ inches diameter, and 8 feet 8 inches circumference, marking one rod in two revolutions. This is attached to a long

handle of which a person walking pushes it forward. Near the end of the handle is the box containing the index under a glass cover. It is made to point the number of miles and rods travelled over, or any other measures of distance.—The form of odometer carried by pedestrians, and designed for recording the number of steps, is generally called a pedometer. It resembles a watch in size and shape, and may be worn in the vest pocket. Its machinery is so constructed that by the rising and sinking of the body with each step a lever is made to vibrate, which moves the index hand connected with it. In London odometers have been contrived for hackney carriages to serve for the proprietors or for the passengers as checks upon the distance travelled. By one form of this apparatus, patented in 1851, the box containing the train of wheels attached to the side of the carriage is provided with two dials, one of which is outside for the use of the passenger or driver, and the other inside for the protection of the proprietor and accessible only to him.

O'DONNELL, LEOPOLD, count of Lucena and duke of Tetuan, a Spanish soldier and statesman, born in 1808. He is descended from an Irish family of considerable importance under the later Stuarts, which after the battle of the Boyne emigrated to Austria. Several of its members became distinguished in the imperial service, and one of them, finding his way to Spain, founded there a Spanish branch of the family. Leopold O'Donnell, the subject of this memoir, is a son of a Spanish general of some reputation in the early part of the present century, under whose influence he entered the army, and before the age of 25 attained the rank of colonel. The Carlist war, in which he sided with the young queen, first brought him prominently into notice; and for his services in raising the siege of Lucena he was created count of Lucena, and received from Espartero the appointment of chief of the staff and the command of the army of the centre. He subsequently attached himself to the cause of Queen Christina, with whom, upon the elevation of Espartero to the regency, he was obliged to take refuge in France. In 1841 he was permitted to return to Spain upon pledging his fealty to the established government; but he almost immediately joined the revolutionists who were endeavoring to overthrow Espartero. Defeated at Pampeluna, he again took refuge in France, whence, upon the retirement of Espartero in 1843, he returned to Spain, and was rewarded for his persevering efforts against the regent by being appointed captain-general of Cuba, where he is said to have amassed a fortune. After his return to Spain he busied himself again with political intrigues, and, upon threatening to exert his influence against the government, was appointed by Narvaez director-general of the infantry, which office he retained until 1851, when the jealousy of Narvaez caused his dismissal. He again joined the

opposition, and during the succeeding Sartorius ministry became so deeply implicated against the court and Queen Christina, that at the commencement of 1854 he was proscribed and obliged to conceal himself. In June he headed a revolt, was defeated in Vicalbaro, took refuge in Andalusia, and under the pressure of the moment sided with the *progresista* party and issued a manifesto, demanding the restitution of the constitution of 1837, the emancipation of Queen Isabella, the perpetual banishment of the queen mother, the amelioration of the laws regulating the elections and the press, the reduction of taxes, and other popular measures. At this crisis Espartero was invited by the queen to form a ministry; he accepted, and in company with O'Donnell made a triumphal entry into Madrid on July 29. O'Donnell soon after received the portfolio of the war department, and was appointed a marshal. But he had little sympathy for the liberal measures proposed by Espartero, and to his efforts the dismissal of that minister in July, 1856, is mainly ascribed. He succeeded him as president of the council, and inaugurated his administration by declaring Spain under martial law, closing the cortes, abolishing the national guard, and by other absolute measures. Insurrections followed, which, however, were generally suppressed; but Narvaez having successfully plotted against him, he was, in Oct. 1856, obliged to retire from office. He returned to power again in 1858, and in 1859 held the double position of prime minister and commander-in-chief of the forces engaged in the war in Morocco. (See Morocco.) For his services in the latter capacity he was created duke of Tetuan. He is a man of imposing presence, and of an aspect said to be more Irish than Spanish.

ODYSSEY. See HOMER.

ECOLAMPADIUS, or OXOLAMPAD, JOHANNES, the Græcized name of Johann Hauschein, but whose real name, according to recent investigations, was Hussgen or Heussgen, a German reformer, born in Weinsberg, Swabia, in 1492, died in Basel, Nov. 24, 1581. His father was a merchant, and at first intended him for the same career. But his mother "desired to consecrate her only son to learning and to God," and he himself was averse to business, and fond of literary pursuits. He entered the university of Heidelberg at 12 years of age, went thence to Bologna to study jurisprudence, and returned to Heidelberg, where he studied theology. He was afterward tutor to the son of the elector palatine, and then held a benefice founded by his parents, but resigned both functions in order to continue his theological studies at Tübingen and at Stuttgart. He had already while in Heidelberg formed a friendship with Capito, the preacher and reformer, and through him with Erasmus, for whom he had the most ardent admiration. After preaching for a short time with great success in Weinsberg, he was in 1515 invited to Basel, and while there

assisted Erasmus in his "Annotations on the New Testament." About the end of 1518 he was invited to Augsburg. He found the city excited by a recent conference between Luther and the papal legate. Obligated to choose one side or the other, he declared for Luther. A violent dispute ensued, and being constitutionally timid, and wanting as he thought in the qualities which make a successful minister, he retired in 1520 to a convent of the monks of St. Bridget, near Augsburg. But here his position was still more uncomfortable. He stood at this time midway between Luther and Rome, desiring a "certain purified Catholicism," but was inclining more and more toward the side of Luther. He left the convent, after having been there nearly two years, and took refuge in the castle of Ebernburg, where for a time he was preacher to Francis of Seckingen. In 1522 he went to Basel, where he became curate of St. Martin's, and subsequently professor of theology, drawing large audiences whenever he preached or lectured. He led the discussion at the conference in Baden, in 1526, against Eck, and was distinguished there for his mildness and ability. In Jan. 1528, he attended a conference in Bern. His mother dying soon after his return, he resolved to take a wife, having written against the celibacy of the clergy some years before. He married Wili-brandis, daughter of a knight of the emperor Maximilian; which gave occasion for the remark of Erasmus: "Luther's affair is called a tragedy, but I maintain it is a comedy, for each act of the drama ends in a wedding." He supported Zwingli in his dispute with Luther respecting the real presence in the Lord's supper, and published a treatise entitled *De Vero Intellectu Verborum Domini: Hoc est Corpus meum* (1525), in which he maintained the word *corpus* to be only symbolical. He took the same ground at the celebrated conference at Marburg in 1529, where with Zwingli he disputed against Luther and Melancthon. Although Luther differed so much from him, Ecolampadius was one of the few among his opponents whom he still loved. On the death of Zwingli he was invited to Zürich to take his place; but in a letter addressed to the great reformer, March 26, 1526, he complained of being a *perpetuus valetudinarius*, and died soon afterward. His name stood second only to that of Zwingli, and he was called the Melancthon of Switzerland. He was a tall, handsome man, of a patriarchal presence, taking more delight in studies and spiritual exercises than in active intercourse with the world, into which he was drawn only by the command of his conscience and the necessities of his times. His widow became the wife of Capito, and after his death she married Bucer. His principal works are: *Annotationes in Genesin*; *Exegemata in Librum Job*; *Commentariorum in Esaiam libri sex*; *De Ritu Paschali*; and *Quod non sit onerosa Christianis Confessio*. His life was written by Hess (Zürich, 1791), and by Herzog (Basel, 1843).

CECUMENICAL COUNCIL. See COUNCIL.

CEDEMA (Gr. *oedema*, from *oidea*, to swell), a swelling occasioned by the infiltration of serum into the areolar tissue of a portion of the body. The limits between oedema and anasarca are not very strictly defined, being those of degree merely. Anasarca, arising from disease of the heart or kidneys, commences with oedema, which as it becomes general assumes the name of anasarca. Any thing which interferes with the return of the venous blood from a part may produce oedema; thus in pregnant women the pressure of the uterine tumor upon the great veins within the abdomen, may cause oedema of the lower extremities; and the same result follows in feeble persons the long maintenance of the upright position, the blood having to return against the force of gravity. Obliteration of any of the large venous trunks by adhesive inflammation is followed by oedema of the parts whose blood was returned by the obliterated trunk; thus phlegmasia dolens is caused by inflammation and plugging up of the femoral or iliac veins. The pressure of an aneurism or other tumor within the chest, upon the vena cava or vena innominata, may produce oedema of one half or the whole of the upper part of the body. Paralyzed limbs frequently become oedematous from the venous circulation no longer being aided by the contraction of the muscles of the part. Certain conditions of the blood, such as occur in chlorosis and scurvy, are favorable to the occurrence of oedema. In all these instances the oedema is of a passive kind; but the same symptom occurs as an attendant on some forms of inflammation, particularly a variety of erysipelas, hence termed oedematous erysipelas. In all instances oedema is simply a symptom produced by different causes, and is to be treated according to the cause by which it is produced. Two varieties of oedema, that of the glottis and that of the lungs, from their importance arising from the nature of the organs affected, deserve special mention.—Oedema of the glottis may occur from exposure to cold and moisture, as a consequence of tonsillitis and other affections, the inflammation extending to the larynx, or in the course of various diseases, as erysipelas, typhoid fever, &c. The patient is conscious of an increasing impediment in his respiration, and of a sense of stricture about the larynx. There is a dry hoarse cough coming on in paroxysms, with fits of suffocation, while the voice is hoarse, whispering, and finally extinct. Inspiration is prolonged and difficult, while expiration is comparatively unaffected. Sometimes, but not invariably, there is soreness of the throat and difficulty of swallowing. The pulse, at first unaffected, as the difficulty of breathing increases becomes small and frequent, and the body is bathed in perspiration. Death from suffocation sometimes takes place a few hours after the commencement of the attack. On post mortem examination the cellular tissue underneath the mucous membrane lining the glottis is found infiltrated by

serum, narrowing the opening of the glottis and having a sort of valvular action in inspiration. When violent the disease rarely leaves much time for treatment. Schönlein of Berlin first suggested the operation in Europe, and Dr. J. O. Peters in America. But Dr. Gurdon Buck of New York was the first to carry it into effect, and has relieved numerous cases of this affection by nicking the oedematous mucous membrane, and thus giving exit to the effused serum which is the cause of the difficulty. For this purpose he has devised a peculiar narrow probe-pointed bistoury. The fore finger of the left hand being carried boldly down to the laryngeal opening and pressed upon this as a guide, several minute incisions are made in the mucous membrane of the glottis. When Dr. Buck's operation does not succeed, recourse must be had to tracheotomy.—Oedema of the lungs occurs in heart disease as a consequence of the embarrassed condition of the circulation through the lungs, in albuminuria (see ALBUMINURIA), in typhus and typhoid fevers, in anæmia, and in pneumonia and bronchitis. Its symptoms are difficulty of breathing, in some cases extreme, and a sensation of weight or constriction in the chest. There is teasing cough with a watery and sometimes viscid expectoration. On physical examination the percussion note is but slightly affected; auscultation gives a smooth, moist, fine, sub-crepitant rhonchus. The treatment, when treatment is necessary, is that of general dropsy.

OEDENBURG (Hung. *Soprony*), a town of W. Hungary, capital of a county of the same name, near Neusiedler lake, on a branch of the Vienna and Cilly railway, 87 m. S. S. E. from Vienna; pop. 15,000, chiefly Germans. It is neatly built, and has several fine churches, both Catholic and Lutheran, colleges of both creeds, convents, hospitals, barracks, a military academy, a theatre, and a curious watch tower which anciently formed part of its fortifications. It has manufactures of cotton, woollen, &c., and an active trade in wine.

ŒDIPUS, a mythological king of Thebes, whose life formed a favorite subject for the tragic poets of antiquity. According to the common form of the legend, he was the son of Laius, king of Thebes, and Jocasta. An oracle having informed Laius that he should be killed by his son, no sooner was Œdipus born than he was exposed on Mt. Cithæron with his feet pierced and bound together. In this situation he was found by a shepherd and brought to King Polybus of Corinth, who being childless adopted him as his own son and called him Œdipus from his swollen feet. He grew up in ignorance of his birth, and once being taunted with not being the son of the king, he consulted the oracle at Delphi. From it he received the answer: "Avoid the soil of thy country, or thou wilt be the murderer of thy father and the husband of thy mother;" and supposing Corinth was meant, he determined not to return. On the road between Delphi and Daulis

he met Laius, and being ordered by the charioteer of the latter to make way an affray ensued in which he killed both his father and the charioteer. At this time the sphinx was laying waste Thebes, proposing a riddle to every passer-by, and devouring all who were unable to solve it; and so great became the devastation, that a proclamation was made by the Thebans, offering the crown and the hand of Queen Jocasta in marriage to him who should free the country from the monster. Œdipus undertook the task, and the following riddle was given him: "A being with four feet has two feet and three feet, and only one voice; but its feet vary, and when it has most it is weakest." This he solved, saying the being was man, who in infancy crawls upon all fours, in manhood walks erect, and in old age supports himself by a staff. The sphinx hereupon destroyed herself, and Œdipus obtained the crown and married his mother, who bore him two sons, Eteocles and Polynices, and two daughters, Antigone and Ismene. A pestilence desolating the land on account of this incestuous alliance, the oracle ordered the expulsion of the murderer of Laius; and a proclamation was issued announcing a curse upon the unknown criminal, and declaring him an exile. Œdipus was hereupon informed by the prophet Tiresias that he himself was the parricide and the husband of his mother. Jocasta hanged herself, and Œdipus put out his eyes. After this, according to one form of the legend, Œdipus was driven from Thebes by his sons and Creon, his brother-in-law, and under the guidance of his daughter Antigone went to Attica. According to another, he became dependent upon his sons, on whom he imprecated a curse, praying to the gods that there might be endless war between them, and that they might perish each by the hand of the other. After Eteocles and Polynices had slain one another, Creon succeeded to the throne and drove out Œdipus, who finally reached the groves of the Eumenides, near Colonus in Attica, where he was received with distinguished honor by Theseus. There he died, and his burial place was concealed by the Eumenides, whose favor he had conciliated. The Homeric account of the tradition is different in several particulars. The tragedies founded upon this legend which Æschylus and Euripides wrote are now lost; but two by Sophocles remain, entitled *Œdipus Tyrannus* and *Œdipus Colonus*. Seneca also wrote one on this subject, and in modern times Corneille and Voltaire.

OEHLENSCHLÄGER, ADAM GOTTLÖB, a Danish poet and dramatist, born in Vesterbro, a suburb of Copenhagen, Nov. 14, 1779, died in Copenhagen, Jan. 20, 1850. His parents were of German extraction, and his father, the descendant of a long line of schoolmasters and organists established in Krusendorf, Schleswig, entering the service of Count Adam Gottlob Moltke (after whom the poet was named), was by the influence of that nobleman appointed

steward of the royal palace of Frederiksborg, situated about 2 miles from Copenhagen. In this building was passed the early life of young Oehlenschläger, who in his *Erindringer*, a minute autobiography coming down to a late period of his career, has described the impression which the place, its associations and surroundings, and the occasional presence of the court, made upon his boyish imagination. At 13 years of age he was placed in one of the public schools of Copenhagen, and soon after began to write verses and even plays, which were performed in one of the rooms at Frederiksborg by himself and some of his schoolfellows. At the same time he was a diligent reader of novels in the Danish language, over which he thereby obtained a remarkable mastery. When about 18 years of age he was possessed with the desire of going upon the stage; but finding his chances of success not very encouraging, he relinquished the idea, and under the influence of two young students, the brothers Oersted, who afterward gained distinction in the walks of natural science and jurisprudence, he commenced the study of the law in the university of Copenhagen. His literary tastes soon led his thoughts into other channels, and in 1803 he ventured before the public as the author of a volume of poems containing, among other things, the play of "The Eve of Saint John," which, with the drama of "Aladdin" published soon afterward, brought him into considerable notice, and procured for him in 1805 a traveling stipend from the government. Proceeding at once to Germany, he made the acquaintance of Goethe, Tieck, Wieland, Hegel, and other distinguished literary men, and cultivated the language of the country with so much success, that he was soon enabled to translate his works as fast as composed into German. At Halle he wrote his "Hakon Jarl," the first and one of the finest of his purely Scandinavian tragedies; and at Paris, whither he proceeded in 1806, and where he remained two years, he produced "Palnatoka," considered by some his masterpiece, and "Axel and Valborg," all dramas of powerful interest, not less on account of their national tone and spirit, than of the vivacity and variety of the action, and the picturesque manner in which the incidents, thoughts, and manners of distant ages are brought before the reader. He next visited Italy, and while residing in Rome in intimate personal relations with his countryman Thorwaldsen, he composed his "Correggio," an art drama founded on the life and character of the great painter of Parma, and originally written in German. It was subjected to severe criticisms from some of the author's most illustrious literary friends, but became an exceedingly popular acting play on the German and Danish stage. An English translation of it by Theodore Martin was published in 1854. After about 5 years' absence Oehlenschläger returned in 1810 to Denmark, the first of living Danish poets, and among the first of modern dramatists. He soon after ob-

tained the professorship of *aesthetics* at the university of Copenhagen, was married, and commenced an active literary career, which was continued, with few intermissions, until the close of his life. He wrote not merely dramas, but novels, poems, translations, and a great variety of miscellanies; and as he advanced in years he became the recipient of honors from his sovereign and countrymen, who gloried in his literary reputation, and from other European nations. Visiting Sweden in 1829 for the first time in his life, he was welcomed with an extraordinary ovation by the inhabitants of Lund, in which Bishop Tegner and other eminent men took part; and subsequent visits made by him to Norway and Sweden "were like triumphal processions of a sovereign in literature." On his 70th birthday a grand festival was given in his honor in the royal shooting gallery at Copenhagen, in which the chief poets of Denmark participated. In less than 3 months afterward he died, an extract from his own tragedy of "Socrates," in which Socrates speaks of death, having at his request been read to him during his last moments. His funeral was attended by 20,000 persons, including those most eminent in literature, art, science, and the public service. His tragedies, on which his fame chiefly rests, are 24 in number, 19 being devoted to Scandinavian subjects. Of the latter, in addition to those mentioned, the most striking are "Canute the Great," "The Varangians in Constantinople," "Land Found and Lost," illustrating the early voyages of the Northmen to America, "Dina," and "Tordenakiold." To these must be added a number of dramatic pieces in a lighter vein, the whole forming a series "which for extent and value no other author of the 19th century can rival." His remaining works of imagination, whether in poetry or prose, are of less merit, the best being the *Nordens Guder* ("Gods of the North"), published in 1819, in which he attempted with success to collect into one whole the scattered legends of the Eddas. An English metrical translation of this by W. E. Frye was published in Paris in 1845. Oehlenschläger also translated the "Midsummer Night's Dream" and Beskav's Swedish dramas into Danish, and Holberg's "Danish Theatre" into German. His collected works in Danish, including his *Erindringer* or "Recollections," an autobiography, amount to 41 vols.; those in German of all kinds to 21. A series of elaborate articles, by R. P. Gillies, on his dramas, accompanied by copious translations, appeared in "Blackwood's Magazine" in 1820-'71. Oehlenschläger was a man of great purity of heart and simplicity of character, and genial, childlike manners. Self-esteem was one of his chief characteristics; but apart from the fact that it was grounded on genuine merit, he is known to have regarded himself only as the medium through which an inspiration from a higher source spoke, and his poetry as the result of that inspiration.

OERSTED, ANDERS SANDØZ, a Danish statesman, born in Rudkjøbing, in the island of Langeland, Dec. 21, 1778, died in Copenhagen, May 1, 1860. He was educated with his brother Hans Christian at the university of Copenhagen, where he formed an intimacy with Oehlenschläger, whose sister he subsequently married. In 1799 he passed his examination for admission to the bar, and soon took rank as one of the ablest advocates in Denmark. After filling various public offices, he was in 1825 appointed attorney-general, in which capacity he drew up many of the important ordinances then constituting the laws of Denmark. After the revolutionary movements in Europe of 1830-'1, he assisted in framing the constitution demanded by the provincial states of the kingdom, at the assembly of which he for several years represented the king, as high commissioner, with great acceptance. Between 1841 and 1848 he held a seat in the Danish cabinet, and, in Oct. 1853, was appointed by Frederic VII. prime minister. The reactionary character of the propositions advanced by him, one of which was the right of the king to grant new constitutions to Holstein and Schleswig without consulting the diet, brought him into great disfavor, and the chambers clamored for his dismissal. He was sustained by the king; but after a severe constitutional struggle the latter was obliged to yield, and in Dec. 1854, the unpopular ministry was dismissed. Articles of impeachment were subsequently preferred against Oersted and his colleagues, who were tried by a commission composed of 8 members of the supreme tribunal (*høests ret*), and as many from the *landthing* or upper house of the diet, and acquitted, the votes for and against their conviction being equally divided. He afterward lived in retirement, engaged in completing a work of an autobiographical character entitled "Fragments of the History of my Life and Times," of which the 4th volume appeared in 1856. As a jurist he established a considerable reputation by the publication of several law treatises, and as editor of three successive legal periodicals. He also produced several works on philosophy, in which he adhered to the school of Hegel. Among his latest publications was a work on "Scandinavian Politics in Modern Times" (8vo., Copenhagen, 1857).

OERSTED, HANS CHRISTIAN, a Danish natural philosopher, brother of the preceding, born at Rudkjøbing, Aug. 14, 1777, died in Copenhagen, March 9, 1851. He was the son of a druggist in moderate circumstances, whom at the age of 12 he assisted in his business. Possessing a fondness for the physical sciences, he repaired in 1794, in company with his brother, to the university of Copenhagen, where, pinching themselves in the matter of food and lodging, they pursued their studies with singular earnestness. Hans Christian, at the same time, became imbued with the modern German philosophy, then first promulgated in the Dan-

ish capital through the lectures of Steffens, and competed successfully for the university prize medal on the subject of the "Limits of Poetry and Prose." In 1799 he took his doctor's degree, presenting for the occasion his "Architectonics of Natural Metaphysics," in which were embodied the fruits of a patient study of the laws of physics and of their higher relations as the products of reason. In 1800 he took charge of an apothecary's shop, and, devoting his attention to galvanism, made important discoveries with respect to the action of acids during the production of galvanic electricity. He was one of the first to show the opposite conditions of the poles of the galvanic battery, and that acids and alkalis are produced in proportion as they neutralize each other. In 1801-'3 he studied and travelled in Germany, France, and Holland, and upon returning to Copenhagen lectured on electricity and the cognate sciences. About the same time he commenced a series of articles on "Acids and Bases" in Gehlen's "Journal," and produced a number of scientific papers in German and Danish, a selection from which, showing the poetico-philosophical tendency of his mind, has been reproduced in English by the Misses Horner, under the title of "The Soul in Nature, with Supplementary Contributions." In 1806 he became professor of physics in the university of Copenhagen, and in 1809 published the first edition of his "Manual of Mechanical Physics." In 1812 he revisited Germany, and at the suggestion of Niebuhr published at Berlin a work tending to show the identity of chemical and electrical forces, which is considered to have unfolded the germ of his subsequent discovery in electro-magnetism. The latter was made in the winter of 1819-'20, while Oersted was engaged in a special study of the connection of magnetism and electricity. He was lecturing one day to a class of advanced students, when it occurred to him, as a means of testing the soundness of the theory which he had long been meditating, to place a magnetic needle under the influence of a wire uniting the ends of a voltaic battery in a state of activity. He tried the experiment upon the spot, and found that the needle tended to turn at right angles to the wire, thus proving the existence of electro-magnetism, or the relation of electricity and magnetism as mutually productive of each other, and as evidences of a common source of power. Previous to this time the identity of magnetism and electricity had only been suspected. For several months Oersted prosecuted experiments on the subject, and in July, 1820, promulgated his discovery in a Latin tract entitled *Experimenta circa Efficaciam Conflictus Electrici in Acum Magneticam*, in which he contended that "there is always a magnetic circulation around the electric conductor, and that the electric current, in accordance with a certain law, always exercises determined and similar impressions on the direction of the magnetic

needle, even when it does not pass through the needle, but near it." The principal experimenters of Europe immediately busied themselves in the verification of this discovery. Testimonials were showered upon Oersted from every European capital; the French institute presented him with a prize worth 8,000 francs; the royal society of London bestowed upon him the Copley medal; and by common consent he was elevated to the first rank of scientific men. For a number of years subsequent he pursued his inquiries in the wide field of miscellaneous physics, the fruits of which appeared in numerous papers and scientific memoirs. At intervals he undertook scientific missions to various parts of Europe, and founded the magnetic observatory of Copenhagen, and also the Danish society for the diffusion of natural science, one object of which was to send forth a body of popular lecturers over the kingdom. In 1844 appeared the 2d edition of his "Manual of Mechanical Physics," which, among other valuable additions, contained accounts of his experiments on the compressibility of water and air. Amid his engrossing scientific studies he also found time to cultivate Danish literature and politics, and, beside producing a lyrical and didactic poem called "The Balloon," was a frequent contributor of important information to the newspapers, and the intimate associate of the chief literary men of Copenhagen. He was a friend of liberal constitutional ideas, and in 1835 aided in founding a society for securing the freedom of the press, although his position and inclinations as a man of science afforded him few opportunities for direct action in political life. Honors crowded upon him during his latter years, and the 50th anniversary of his connection with the university of Copenhagen (Nov. 7, 1850) was celebrated by an extraordinary jubilee, in which deputations from the king and ministry and the chief scientific institutions of the country participated. His death in the succeeding spring called forth a universal expression of sorrow, and his funeral was attended by one fourth of the population of Copenhagen, the procession being headed by the representative of the king and by the crown prince. Throughout his scientific career Oersted labored to show that the laws of nature must harmonize with reason, even representing the practice of science to be a religious worship. He engaged in several warm controversies on this topic. Sir Humphry Davy, who visited him in Copenhagen, considered him a man of simple manners and not of extensive resources; but Niebuhr, viewing his character in another light, declared that he "scarcely knew another natural philosopher with so much intellect and freedom from prejudice and *esprit de corps*." His manners were eminently pleasing and simple, and in all the relations of life he sustained an unblemished reputation. As a lecturer he possessed great merit, and was one of the first to give popular

lectures to ladies on scientific subjects, and to urge the establishment of female colleges.

OESSEL, an island in the Baltic, at the mouth of the gulf of Riga, comprised in the Russian government of Livonia, between lat. 57° 40' and 58° 14' N., and long. 21° 40' and 23° E.; length about 60 m., breadth from 8 to 50 m.; area, 1,200 sq. m.; pop. 40,000. It has a bold, high coast, and a diversified surface. The climate is more temperate than on the mainland, but violent storms happen frequently in spring and autumn. The soil, though not naturally fertile, is watered by many small streams and capable of being easily improved. A great part of the island is covered with forests, and a considerable extent of it is used as pasture ground. Grain is raised for exportation. The only important manufacture is tar. The fisheries on the coast, chiefly of seals, are valuable. The chief town is Arensburg on the S. E. side. The majority of the people are Lutherans. Oessel at one time belonged to the Teutonic knights, but was seized by the Danes at an early period, and ceded by them to Sweden in 1645. In the beginning of the 18th century Russia took possession of it, and in 1721 it was formally ceded along with Livonia to that power.

OETTINGER, EDUARD MARIA, a German miscellaneous author of Jewish parentage, born in Breslau, Nov. 19, 1808. After studying at a private school he went to Vienna to complete his education. Having adopted the Roman Catholic religion, he entered upon the career of a journalist, and afterward edited journals, mostly of a humorous and sarcastic character, in Berlin, Munich, Hamburg, Mannheim, and Leipsic. In 1852 he was living in Paris, whence he removed in 1853 to Brussels. Oettinger has written several romances, among which the most noteworthy are "The Ring of Nostradamus" (1838); "Uncle Zebra" (1842-'3); "Sophie Arnould" (1847); "Potsdam and Sans-Souci" (1848); and "Jerome Napoleon and his Capri" (1853). Several of his poems have become very popular. His writings are marked by an unmistakable talent for sarcasm, and by a playful vivacity, which is especially apparent in the "Grammar of Marriage" (1844), and in the "Art of Becoming a Gentleman in 24 Hours" (1852). In the department of bibliography his works are noteworthy; among them are *Archives historiques* (1841), *Bibliotheca Schahiludii* (1844), *Iconographia Mariana* (1852), and *Bibliographie biographique* (1850; 2d edition enlarged, Brussels, 1854).

OFEN. See BUDA.

OFFENBACH, the chief manufacturing town of Hesse-Darmstadt, on the S. bank of the Main, 4 m. S. E. from Frankfurt; pop. about 18,000. It has manufactories of cotton and woollen fabrics, carriages, cards, musical instruments, jewelry, &c.

OG, king of Bashan, one of the two kings of the Amorites who withstood the invasion of the Israelites under Moses. He was utterly defeated at Edrei, and all his cities, threescore

in number, were taken, and his kingdom was given to the half tribe of Manasseh. In stature he was a giant, his bedstead, which was kept in Rabbath-Ammon, being 9 cubits in length and 4 in breadth.

OGDEN, AARON, governor of New Jersey, born in Elizabethtown, N. J., Dec. 8, 1756, died in Jersey City, April 19, 1839. He was graduated at Princeton college in 1778. In 1777 he joined the army, and served with distinction during the whole revolutionary war. After the war he practised law; was a presidential elector in 1800, and was appointed one of the commissioners for adjusting the disputed boundary between the states of New York and New Jersey. From 1801 to 1808 he was U. S. senator; in 1812 was governor of New Jersey; and for the remainder of his life was engaged in the practice of his profession.

OGDENSBURG, a village of Oswegatchie township and port of entry of St. Lawrence co., N. Y., on the St. Lawrence river, at the mouth of the Oswegatchie, opposite Prescott, C. W., and 210 m. N. N. W. from Albany; pop. in 1860, 7,418. It is at the foot of sloop navigation upon the great lakes and the St. Lawrence, and is the W. terminus of the northern railroad extending to Rouse's Point, at which there are connections with New York and Boston. It has an active coast trade and some manufactories, the Oswegatchie river furnishing water power. It contains a custom house, town hall, an armory, an academy, and several churches. The exports for the year ending June 30, 1859, amounted to \$356,251, and the imports to \$1,017,281; clearances 283, tonnage 146,405, of which 136 were American, tonnage 115,106; entrances 282, tonnage 145,355, of which 135 were American, tonnage 114,201. The aggregate tonnage of the district is 7,979. The village is connected with Prescott by a steam ferry.

OGGIONE, or UGGIONE, MARCO DA, an Italian painter, born in Oggione, near Milan, about 1470, died in 1530. He was a pupil of Leonardo da Vinci, and according to Lanzi one of the best painters of the Milanese school. He worked in oil and in fresco. His chief works are the frescoes executed for the church della Pace in Milan, and now deposited in the Brera in the same city. At the present day he is perhaps best known by his celebrated copy of Da Vinci's "Last Supper," executed about 1510 for the refectory of the Certosa di Pavia, and now in the royal academy in London. Having been painted when the original was in a perfect state by a favorite pupil of Da Vinci, it is justly considered to give a far better idea of Leonardo's masterpiece than the few remains of the work itself that are visible.

OGILVIE, JAMES, a Scotchman of noble family, born about 1760, died in Aberdeen, Sept. 18, 1820. Emigrating to America, he became embarrassed in his resources, and founded a classical academy at Richmond, Va., where he taught many pupils who after-

ward became celebrated. Among these were Gen. Scott, General and Commodore Jones, the Hon. William S. Archer, and others widely known in the national councils. After some years spent in Virginia, he retired to the backwoods of Kentucky, where, alone in a rough log cabin, he composed a series of striking lectures which were repeated with great applause in Virginia and throughout the Atlantic states. At this time he publicly renounced the infidel opinions which he had previously held, but probably returned to them eventually. His relative, the earl of Findlater and Airy, dying without children, he returned to Scotland, and claimed the title. On his way he lectured in London before the Surrey institution, his fame in America having reached England. The attempt ended however in failure. The habitual use of narcotics had undermined his intellect, and he retired in confusion from the hall. Soon after reaching Scotland, worn out in body and mind, he perished probably by his own hand.

OGILVIE, JOHN, a Scottish divine and poet, born in Aberdeen in 1738, died in Midmar, Aberdeenshire, in 1814. He was educated at the Marischal college in Aberdeen, and in 1759 was settled as minister of the parish of Midmar, with which he remained connected during the remainder of his life. He wrote "The Day of Judgment," a poem (1758); "Providence, an Allegorical Poem" (1763); "Solitude, or the Elysium of the Poets" (1765); "Paradise," and other poems; and also various critical and theological works, including "An Inquiry into the Causes of Scepticism and Infidelity in all Times" (1783), "The Theology of Plato compared with the Principles of the Oriental and Grecian Philosophers" (1798), &c. He was a man of undoubted genius, but, according to one of his biographers, used his powers with little effect, and "wasted his intellectual wealth and industry in huge and unhappy speculations."

OGILVY, JOHN, a Scottish poet and geographer, born in Edinburgh in 1600, died in London, Sept. 4, 1676. While a boy he removed with his parents to London, where he subsequently adopted the profession of dancing master, in which capacity he was employed by the duke of Buckingham and other noblemen. Through the influence of the earl of Strafford he was appointed master of the revels in Ireland; but the civil wars having ruined his prospects in that country, he returned to England, and to remedy the defects of his early education went through a course of study at Cambridge. In 1649 he published a metrical translation of Virgil; in 1651 "The Fables of Æsop, paraphrased in Verse," with commendatory verses by Sir William Davenant and James Shirley; in 1655 a second volume of translations from Æsop, with some original poems; and in 1660 a metrical translation of Homer, which was a favorite with Pope in his younger days, and may have suggested his own

translation. In the last named year he produced a fine edition of the Bible accompanied by plates. At the restoration he was reappointed master of the revels in Ireland, but was ruined by the fire of London, and being named cosmographer and geographic printer to the king, published 9 volumes of a great descriptive "Geography of the World," and obtained the privilege of disposing of them by lottery; of these, "America" (fol., London, 1671) is curious and valuable.

OGINSKI, a princely family of Lithuania, various members of which have played an important part in the history of Poland, especially in the 18th century. At the beginning of that century, when Charles XII. of Sweden, in his war against Peter the Great and his allies, invaded the country, a bloody feud of the family against the rival house of the Sapiehas was terminated by a victory of the latter. The following Oginskis distinguished themselves in a more recent period. I. MICHAŁ KAZIMIERZ, born in Warsaw in 1781, died there in 1803. He lived for some time on his estate at Slonim, surrounded by a circle of scholars and artists, of whom his own accomplishments, especially in music, made him a worthy compeer. He subsequently joined the patriotic movement of the confederation of Bar against the Russians, and became an exile at the first division of Poland in 1772; but having in 1776 gained liberty to return, and recovered a part of his confiscated estates, he was still able to construct at his own expense the canal which bears the name of his family, dying shortly before its completion. This canal connects an affluent of the Niemen with an affluent of the Pripetz, the tributary of the Dnieper, and thus forms a link for direct navigation between the Baltic and Black seas. II. MICHAŁ KŁEOFAS, nephew of the preceding, born in Warsaw in 1765, died in Italy in 1831. He was deputy to the Polish diet, envoy extraordinary to the government of the Netherlands, and in 1794, on the outbreak of the revolution under Kosciuszko, commander of a regiment of volunteers equipped at his own expense. After the fall of Praga and the final extinction of Polish independence, he made unsuccessful attempts to gain the assistance of the French republic and the Porte in projects for the regeneration of his country. In 1802 he accepted an amnesty of the emperor Alexander, and subsequently also a place as secret councillor and senator in his service. In 1815 he settled with his family in Italy, where he acquired great celebrity as a musical composer, especially of polonaises, and also as the author of *Mémoires sur la Pologne et les Polonais depuis 1788-1815* (2 vols., Paris, 1826), an important contribution to the history of that memorable period.

OGLETHORPE, a N. E. co. of Ga., bounded N. by the Broad river and two of its branches, and S. W. by the Oconee, and drained by a number of creeks; area, 480 sq. m.; pop. in 1859, 11,820, of whom 7,649 were slaves. It

has a hilly surface and a generally fertile soil. The productions in 1850 were 445,575 bushels of Indian corn, 99,771 of oats, 76,407 of sweet potatoes, and 12,249 bales of cotton. There were 6 saw mills, a grist mill, 2 tanneries, 23 churches, and 350 pupils attending public schools. It is intersected by the Athens branch of the Georgia railroad, which passes near the capital, Lexington.

OGLETHORPE, JAMES, the founder of the colony of Georgia, born in Godalming, Surrey co., England, probably in Dec. 1668, died at Oranham hall, Essex, June 30, 1785. He was entered of Corpus Christi college, Oxford, but seems to have been early attracted toward a military career, in which two of his brothers had embarked. In 1714, having for several years held the rank of ensign, he was commissioned an officer in the queen's guards, in which capacity he made so favorable an impression on the duke of Marlborough by his personal beauty, courage, and manly bearing, that the latter recommended him to Prince Eugene, by whom he was appointed one of his aides-de-camp. With Eugene he participated in the campaigns against the Turks in 1716-'17, and took an active command at the celebrated siege and battle of Belgrade. Although invited to remain in the imperial service, he returned in 1722 to England, and in the same year was elected to parliament from the borough of Hazelmere, which he continued to represent during a period of 32 years. The native benevolence of his character was soon after displayed in his successful efforts in parliament to improve the condition of the poor debtors confined in the London prisons, a graceful allusion to which was made by Thomson in his "Winter." Stimulated by his success in this instance, he began to mature a plan for a colony in North America, which should afford an asylum for the oppressed Protestants of Germany and other continental states, "and for those persons at home who had become so desperate in circumstances, that they could not rise and hope again without changing the scene and making trial of a different country." A definite shape was soon given to this enterprise, the credit of originating which belongs wholly to Oglethorpe, and the unoccupied territory lying between Carolina and Florida was selected for the experiment. In June, 1732, 21 "trustees for founding the colony of Georgia" were incorporated by letters patent; and in Jan. 1733, a party of colonists, under the guidance of Oglethorpe, who was appointed governor of the colony, arrived at Charleston. The narrative of his career in Georgia until his final return to England in 1743 will be found in the article GEORGIA. Charges were brought against him for the failure of the enterprise which he had conducted against St. Augustine, but he was honorably acquitted; and during the invasion of the young pretender in 1745 he was appointed a major-general. He followed the enemy on their retreat with considerable activity, but failed to overtake them. His conduct

having again become the subject of official inquiry, he was again honorably acquitted. The remainder of his career, though less marked by active exploits, was rendered conspicuous by the social position which he occupied, his friendship with eminent men, and his vigor of mind and body, which to the very close of his long life gave no indications of decay. Boswell says of him: "This extraordinary person was as remarkable for his learning and taste as for his other eminent qualities; and no man was more prompt, active, and generous in encouraging merit;" and Dr. Johnson thought so highly of his character and public services, that he offered, if furnished with materials, to write the general's life. In 1765 he received the rank of general of all his majesty's forces, and for many years before his death he was the oldest general on the staff. It is said that at the outbreak of the American revolution the post of commander-in-chief of the British forces in America was tendered to him, but that he declined unless authorized to assure the colonies that they should be justly dealt with; whereupon the command was given to Sir William Howe. His interest in American affairs never abated; and he was one of the first to wait upon Mr. Adams, after his arrival in England as ambassador, and express his esteem and regard for America, and his gratification at the termination of the difficulties between Great Britain and her colonies. Of the impression which in extreme old age he made upon strangers the following extract from a letter written by Hannah More in 1784, a few months before his death, will give a favorable idea: "I have got a new admirer; it is Gen. Oglethorpe, perhaps the most remarkable man of his time. He was foster brother to the pretender, and is much above 90 years old; the finest figure you ever saw. He perfectly realizes all my ideas of Nestor. His literature is great, his knowledge of the world extensive, and his faculties as bright as ever. . . . He is quite a *preux chevalier*, heroic, romantic, and full of the old gallantry." Not quite half a century before Pope had spoken of him with equal approbation; and nearly every eminent literary man of the age bore testimony to his noble qualities. A memoir of him by the Rev. W. B. O. Peabody is contained in "Sparks's American Biography," second series, vol. ii.

OGLIO (anc. *Ollius*), a river of northern Italy, flowing through Lombardy. It rises in the Rhetian Alps at the foot of Mount Tonale, in the N. E. part of the province of Bergamo, flows S. W. and afterward S. E., passes through Lake Iseo, and after separating the provinces of Bergamo and Cremona from those of Brescia and Mantua, and receiving the waters of the Mello and the Chiese from the N., joins the Po at Torre d'Oglio, 10 m. S. W. from Mantua. It is 130 m. long. During the winter season it overflows the surrounding country.

OGOBAY, a large river of W. Africa discovered by Mr. Du Chaillu in 1856. Previous to

his explorations the Nazareth, Mexias, and Fernand-Vaz rivers, which fall into the Atlantic respectively in lat. $0^{\circ} 41'$, $0^{\circ} 56'$, and $1^{\circ} 17'$ S., were supposed to be three independent streams; but he has shown that they are all connected with one another, and that the first two are the mouths of a large interior river called the Ogobay, which also feeds in part the Fernand-Vaz through the Npoulounay and Ogooree. The last two have a course of about 20 m., and join the Fernand-Vaz at the distances of 10 and 15 m. from its mouth. Ascending them, Mr. Du Chaillu reached the Ogobay, which here had a W. N. W. course, and attempted to follow it up to its source. After proceeding about 80 m. he came to a lake 40 m. in circumference, called the Anengue, communicating with the river on the right bank by an outlet 5 m. in length. It has low shores, dotted with several villages, and its surface is diversified with elevated and beautiful islands. In the dry season its waters are shallow. Ranges of hills were seen in the distance, but the adjacent country is level, and the outlet of the lake, in which the current was so strong that the canoes could hardly stem it, frequently overflows. The course of the river here changes from S. W. to W. N. W. About 20 m. above the outlet of the lake Mr. Du Chaillu's guides refused to conduct him further lest he should interfere with their trade, and he was compelled to retrace his steps. He learned enough however from slaves to be satisfied that the river was formed about 100 m. further up by the union of two very large main branches, one coming from the N. E. and the other from the S. E.

OGYGES, a king of Thebes or of Attica, the account of whose life belongs more to mythology than to history. He flourished about 1700 B. C., and during his reign the deluge occurred which is called after him the Ogygian. According to one tradition, he was the son of Boeotus, was king of the Ætienes, and the first ruler of Boeotia, which was named from him Ogygia. The oldest gate of Thebes was called the Ogygian gate. He is likewise connected with the Attic legends, and is described as king of Attica, and father of Eleusis and also of Dæira, usually mentioned as the daughter of Oceanus. By Strabo and Polybius he is spoken of as the last king of Achaia, and some legends made him out an Egyptian monarch.

OHIO, one of the north-western states of the American Union, lying between lat. $38^{\circ} 17'$ and $41^{\circ} 57' N.$, and long. $80^{\circ} 34'$ and $84^{\circ} 40' W.$; extreme length 255 m., extreme breadth 180 m.; area, 39,964 sq. m., or 25,576,960 acres. It is bounded N. by Michigan and Lake Erie, E. by Pennsylvania and Virginia, S. by Virginia and Kentucky, and W. by Indiana. The Ohio river extends along half of its E. and the whole of its S. boundary, having a course along the borders of the state of 436 m. The lake shore of Ohio has an extent of 230 m., giving the state a whole navigable water frontier of 666 m. Ohio is

divided into 88 counties, viz.: Adams, Allen, Ashland, Ashtabula, Athens, Auglaize, Belmont, Brown, Butler, Carroll, Champaign, Clarke, Clermont, Clinton, Columbiana, Coshocton, Crawford, Cuyahoga, Darke, Defiance, Delaware, Erie, Fairfield, Fayette, Franklin, Fulton, Gallia, Geauga, Green, Guernsey, Hamilton, Hancock, Hardin, Harrison, Henry, Highland, Hocking, Holmes, Huron, Jackson, Jefferson, Knox, Lake, Lawrence, Licking, Logan, Lorain, Lucas, Madison, Mahoning, Marion, Medina, Meigs, Mercer, Miami, Monroe, Montgomery, Morgan, Morrow, Muskingum, Noble, Ottawa, Paulding, Perry, Pickaway, Pike, Portage, Preble, Putnam, Richland, Ross, Sandusky, Scioto, Seneca, Shelby, Stark, Summit, Trumbull, Tuscarawas, Union, Van Wert, Vinton, Warren, Washington, Wayne, Williams, Wood, and Wyandotte. The chief cities and towns are Columbus (the capital), Cincinnati, Cleveland, Chillicothe, Dayton, Hamilton, Newark, Portsmouth, Sandusky, Springfield, Steubenville, Toledo, and Zanesville. The population of Ohio in 1800 and at subsequent decennial periods was as follows:

Census years.	Whites.	Colored.	Total.	Increase per cent.
1800.....	45,098	887	45,985
1810.....	223,661	1,899	230,760	409
1820.....	576,573	4,893	581,434	152
1830.....	923,829	9,574	937,908	61
1840.....	1,502,123	17,845	1,519,467	62
1850.....	1,955,060	95,279	1,980,329	80
1860.....	2,346,000	18

Of the white population in 1850 (98.72 per cent. of the whole), 1,004,117 were males and 950,938 females; and of the colored (1.28 per cent.), 12,691 were males and 12,588 females. Of the whole, 1,757,556 (88.75 per cent.) were American born, 1,219,482 being natives of Ohio; 218,512 (11.08 per cent.) were of foreign birth; and of 4,261 the origin was not ascertained. Of the foreign-born inhabitants, 111,257 were natives of Germany, 51,562 of Ireland, 25,660 of England, 11,081 of Scotland and Wales, 7,875 of France, 5,889 of British America, and 5,697 of other countries; and of 4,393 the places of birth were unknown. There were 295,458 natives of Ohio residing in other states of the Union. The population was distributed into 848,514 families, occupying 836,098 dwellings. Density of population, 49.55 to the square mile (in 1860, 58.70); proportion to the total population of the Union, 8.54 per cent. There were 947 deaf and dumb, 665 blind, 1,352 insane, and 1,399 idiotic persons. There were 1,077,598 under 20 years of age, 876,108 between 20 and 70, 25,944 between 70 and 100, 58 over 100, and 626 of ages unknown. Occupations of 580,792 males over 15 years of age: 142,687 in commerce, trade, manufactures, mechanic arts, and mining; 270,362 in agriculture; 92,766 in labor not agricultural; 4,109 in lake and river navigation; 9,001 in law, medicine, and divinity; 8,268 in other pursuits requiring education; 1,218 in government civil service; 1,167

in domestic service; and 1,219 in miscellaneous pursuits. Births, 56,884 (2.87 per cent. of the total population); marriages, 22,328 (1.18 per cent.); deaths, 28,949 (1.46 per cent.).—The surface of the state is somewhat diversified, though it has no mountains, presenting on the whole the aspect of a lofty table-land, sinking from 1,000 feet near the centre, where a ridge of low hills forms the water-shed between the rivers of Lake Erie and those of the Ohio, to 600 or 800 feet above the sea on the N. and S. borders. About lat. 40°, a little S. of the middle of the state, there is another range of hills, S. of which lies the most broken part of the state. The belt of land situated between these two ridges is generally flat and in some places marshy. There are prairies toward the N. W. The lake shore is not much indented, though it affords several good harbors, among which are Maumee bay and Sandusky bay. There are several islands in the lake belonging to Ohio. The chief rivers which flow into this great sheet of water from Ohio are the Maumee at Maumee bay, navigable 18 m. by lake steamers; Portage, navigable 12 m.; Huron, navigable 14 m.; Vermilion, Black, Cuyahoga, Rocky, and Chagrine. The smaller streams are principally valuable for their water power, but generally have good harbors at their mouths. The most important tributaries of the Ohio from this state are the Great Miami, which joins it at the extreme S. W. boundary; the Little Miami, Brush, Scioto, Hockhocking, and Muskingum. Several of these have considerable tributaries, and as most of them have moreover long courses, the whole state is abundantly watered. The Great Miami is navigable 75 m., the Scioto 180 m., and the Muskingum 80 m., or at high water 110 m.—The range of the geological formations of Ohio, excepting the drift or boulder formation found in the northern portion of the state, and the alluvium of the rivers and low lands, is included between the coal measures as the upper limit, and the Black river, birdseye, and Trenton group of limestones as the lower limit. The formations are spread over the state in strata so nearly horizontal or gently undulating, that the dip is perceptible only by the passing of one group under another, as the formations are followed over their lines of outcrop. The western half of the state is covered almost exclusively with limestone strata, belonging chiefly to the Niagara group and the lower portion of the Helderberg limestones. In Ohio these formations come together by the disappearance of the Onondaga salt group, which in New York separates them, with its beds of shales, marls, and gypsum of about 1,000 feet in thickness. To this outspread of calcareous strata the western half of Ohio owes its great fertility. In the S. W. corner of the state appear limestones of the lower calcareous group, which are the oldest rocks between the Alleghanies and Missouri. They spread out over a circular area comprising a

few counties in Ohio, Indiana, and Kentucky, and disappear in every direction beneath a narrow belt of shales of the Utica slate formation, which intervenes between these older limestones and those of the Niagara group. The E. limit of the great limestone tract is marked by a line passing from Lake Erie through the central portion of Erie co., across the S. E. corner of Seneca co., and thence a little W. from a southern course to the Ohio river in Adams co., nearly opposite Clarksburg, Ky. East of this succeeds a narrow belt of country occupied by the slates and limestones of the Hamilton group, and next to this the shales and flagstones of the Portage and Chemung group spread over a district from 80 to 40 m. in width, its eastern line crossing the Ohio at Portsmouth in Scioto co. Toward the N. this line bends around in a N. E. direction, passing by Cuyahoga falls, and thence through the S. part of Crawford co., Penn. Thus the whole southern coast of Lake Erie for 30 to 50 m. S. E. from the lake is occupied by this group of shaly strata, which further E. forms the chief part of southern New York. It is from these strata that the material of the clay banks along the southern shore of the lake is derived, and the muddy sediment which after heavy storms from the north discolors the waters of the lake far out from the shore. The red sandstones of the upper devonian and the carboniferous limestones do not appear in Ohio, and the conglomerate or millstone grit, the lowest member of the coal measures, is found overlying the Chemung shales. It enters the state from Pennsylvania in the N. E. corner of Trumbull co., and is thence traced in a narrow belt to Cuyahoga falls, where its beds attain altogether a thickness of about 100 feet. The outcropping edge of this rock, which forms the margin of the coal measures, and indeed the basin itself in which the great Appalachian coal field is contained, is traced S. W. through Wayne and Holmes cos., the S. E. corner of Knox co., and across Licking, Fairfield, Hocking, Jackson, and Scioto cos., to the Ohio river a little above Portsmouth. Along its range it forms frequent vertical cliffs upon the summits and sides of the hills. As it sinks toward the E. the coal measures succeed, and gain in depth as the eastern dip continues into Virginia and Pennsylvania. The lowest beds of coal, with their accompanying beds of slates, sandstones, limestones, and iron ore, are thus found near the line of the conglomerate through the range traced out above, and in an easterly direction pass successively beneath the surface, giving place to higher beds which occupy the hills, and disappear in their turn toward the east. The lower portion of the coal measures contains several valuable beds of bituminous coal, and also strata of iron ore and limestone; and it has been estimated that the resources of this portion of the state in coal and iron ore cannot be exhausted in many thousand years. Though the thickness of the coal beds is not

great, ranging only from 2 to 9½ feet, the quantity of coal they contain is enormous from the extent of the surface they cover, the whole formation overspreading in eastern Ohio about 10,000 sq. m., and that portion of the coal field bordering on Pennsylvania and Virginia including several workable beds, both above the level of the streams and also at different depths below the surface. One of the most productive beds, which is 9½ feet thick, is worked near the dividing lines of Perry and Hocking cos. The iron ores are worked very extensively in the Hanging Rock district near the Ohio river in Lawrence co., and thence N. in the counties lying E. of the outcrop of the conglomerate. In the more northern of these counties the supplies of ore are not so abundant as in the same measures near the Ohio river; and the deficiency is there made up and the furnaces are kept in blast by the Lake Superior ores delivered at Cleveland, and thence transported by canal and railroad into the interior. (See IRON, and IRON MANUFACTURE.) One important member of the lower coal measures has been referred to in the article BURESTONE. This rock accompanies some of the beds of iron ore, and crops out around the steep slopes of the hills in many of the counties from the Ohio river to Stark co., and thence through Mahoning into Pennsylvania. The width of the belt thus occupied by it is from 12 to 20 m., and the thickness of the stratum is from 2 to 9 feet. The rock is a fossiliferous flinty quartz, cellular and excessively hard, of light gray color, and of stratiform structure. It was employed very largely by the Indians for knives, spear heads, and arrow points, and from Jackson to Muskingum co. are innumerable pits made by the aborigines in extracting the hard stone. The quarries of it in the towns of Richland and Clinton in Jackson co. and in Elk in Athens co., and others in Licking and Muskingum cos., have proved very profitable ever since the year 1807, when the stone was first used for millstones. From 1814 to 1820 stones 4½ feet in diameter sold for \$350 a pair, and a pair 7 feet in diameter for \$500. In 1834, 4-foot stones sold for \$150. The rock goes under the Muskingum river two miles above Connellsville in Morgan co.; and at Connellsville it is bored through 110 feet below water, and 650 feet still deeper is found the salt-bearing rock, which for 12 m. further down the river maintains about the same depth below the surface. In this portion of the state and of the coal measures are many salt wells, and in some places the salt water oozes out in springs at the surface. Such springs are found in the valley of Monday creek in Perry and Hocking cos. In 1853 the product of the salt wells at Pomeroy in this vicinity amounted to 1,000,000 bushels. An inflammable gas issues from some of the springs with the salt water. In Southington and in Wethersfield, Trumbull co., burning wells have been opened from which the gas has issued freely, continuing to burn for days together.

These were in the sandstone strata which underlie the coal formation. Natural oil is also found about Mecca, Trumbull co., and wells have recently been sunk for the purpose of collecting it. (See PETROLEUM).—The soil of Ohio is fertile almost without exception. The marshy tracts are capable of being drained, and when this is done are found very productive. The hills are cultivated to their summits, and scarcely any of the land is too rough for tillage. The river bottoms are particularly rich. The climate is temperate on the whole, though the winters are occasionally severe, and tornadoes occur in summer. The average temperature, owing to the elevation of the surface, is several degrees lower than that of the Atlantic states in the same latitude. The valley of the Ohio is less subject to cold and changes of temperature than the interior. Except in some of the marshy districts the climate is healthy, the ratio of mortality, according to the census of 1850, being lower than it is in Connecticut, Kentucky, Louisiana, Maryland, Massachusetts, Missouri, New York, Rhode Island, or the district of Columbia, and about equal to that of Texas. The gradual draining of the swamp lands, which prove particularly fatal to new settlers, has probably done much to lessen the rate of mortality. In judging from the census returns of the state in general, allowance must be made for the high ratio of deaths in some of the large cities, the proportion in Cincinnati for instance being in 1850 as 1 to 37.—Of the wild animals which formerly abounded in this state, very few are now left. The wolf and bear are occasionally seen in the unsettled parts. Deer, raccoons, several smaller animals, and many kinds of feathered game are plentiful.—Ohio was originally covered with heavy forests of oak, walnut, maple, poplar, ash, beech, and cherry, a large part of which still remain, not more than one half of the state being cultivated or fenced. The cypress is almost the only evergreen tree. All kinds of cereals grow in perfection. Indian corn is more at home in the Ohio valley than in any other part of the United States. Wheat has been produced in larger proportion than in any other state of the Union, though for several years past a variety of diseases and a change (supposed to be only temporary) in the climate have greatly diminished the crop. All the small grains have been raised in large quantities, and the cultivation of the grasses, flax, tobacco, and sorghum has been attended with great success. Peaches and other fruit are abundant and excellent in quality. The culture of the grape has received careful attention, and excellent wines are made at and near Cincinnati. (See CATAWBA WINE.) In 1860 the average size of farms was 84 acres; the number of land owners 810,000; the quantity of improved land 18,105,945 acres, an increase of 38 per cent. in 10 years. In 1859 there were 9,851,921 acres of plough land, 8,754,024 of meadow and pasture, and 12,210,184 of wood or uncultivated. Of the plough land

5,229,988 acres were planted in crops, and 800,000 in orchards, gardens, &c. The average price of land of all kinds was \$21 per acre, or nearly equal to the value of land in the best parts of the Atlantic states, and the average sales were 2,024,000 acres per annum. In 1850 Ohio contained 143,807 farms, including 17,997,498 acres (of which 9,851,498 were improved), valued at \$358,758,608; and the value of implements and machinery thereon was \$12,750,585. The principal crops per acre for a series of years past have been as follows: Indian corn, 84 bushels; wheat, 12 bushels; oats, 24 bushels; hay, 1.86 tons. The total products of these crops have been:

Of the minor crops in 1859 there were 576,274 bushels of rye, 1,688,577 of barley, 3,042,176 of buckwheat, and 5,000,000 of potatoes. The aggregate production of grain in 1860 was 183,100,178 bushels, an increase in 10 years of 44,648,049 bushels, or 50 per cent. In 1859 the total cereal product was 107,884,740 bushels, on 5,229,988 acres of ploughed land, or an average of 20 bushels per acre. This is $\frac{1}{4}$ more than the average product of France, and greater than that of the best grain-growing countries of Europe. The number of domestic animals in Ohio at different periods was as follows:

Animals.	1820.	1840.	1860.
Horses and mules	490,527	466,990	702,807
Cattle	1,317,874	1,358,947	1,903,779
Sheep	2,023,401	2,942,929	2,263,174
Swine	2,092,746	1,964,770	2,242,614
Total	5,876,548	7,732,466	6,212,374

The average annual value of farm and dairy products was estimated by the bureau of statistics in 1857 as follows: Indian corn, \$36,000,000; wheat, \$20,000,000; oats, \$6,000,000; other grain, \$2,000,000; potatoes, \$2,000,000; hay, \$20,000,000; fat cattle, \$8,000,000; fat hogs, \$5,400,000; marketable horses, \$6,000,000; marketable sheep, \$400,000; increase of animals, \$2,000,000; wool, \$8,000,000; dairy produce, \$8,500,000; poultry and eggs, \$2,000,000; fruit, wine, sugar, and honey, \$2,000,000; tobacco, \$800,000; flax, vegetables, seeds, and other articles, \$4,000,000; total, \$128,100,000.—According to the census of 1860, there were 54 iron furnaces, which manufactured 106,000 tons of pig metal; an increase of 100 per cent. in 10 years. The quantity of coal mined was 48,000,000 bushels (increase 600 per cent.),

and of salt made 2,000,000 bushels (increase 800 per cent.). The aggregate value of mining products was \$8,880,000, an increase of 400 per cent. In 1850 there were 10,622 establishments engaged in mining, manufactures, and the mechanic arts, employing a capital of \$29,019,538, giving occupation to 51,489 persons, paying \$13,467,660 in wages, consuming \$34,677,987 worth of raw material, and producing \$62,647,259 worth of goods annually. In 1857 the values of the various manufactured products were as follows: iron, \$20,000,000; clothing, \$10,000,000; furniture, \$4,000,000; carriages and wagons, \$1,500,000; spirits, beer, and wine, \$6,000,000; cotton, \$1,500,000; woollen, \$1,500,000; earthenware, \$800,000; animal fat, \$6,000,000; animal meats, \$12,000,000; agricultural machines, \$1,500,000; leather, \$3,000,000; grain, \$8,000,000; wood not included above, \$1,000,000; other articles, \$43,000,000; total, \$119,800,000. The surplus produce of Ohio is exported to the Atlantic markets, nearly $\frac{1}{2}$ of it by railroad and the remainder by the Mississippi river and the great lakes. Their value exceeds \$60,000,000 annually. The principal articles exported, according to the statistical report for 1858, were 2,607,118 bushels of wheat, 2,987,262 of other grain, 1,800,979 bbls. of flour, 877,507 of whiskey, 59,071 of alcohol, 20,427 of beef, 464,457 of pork and bacon, 84,175 of lard, 45,525 of lard oil, 8,785,124 lbs. of butter, 6,786,122 of cheese, 156,096 boxes of candles, 51,728 of soap, 764,560 lbs. of tallow, 740,600 of grease, 118,000 head of cattle, 7,400 horses, 841,595 hogs, 220,657 sheep, 7,572,763 lbs. of wool, 8,700,000 bushels of coal, 20,925,000 lbs. of

tobacco, and 18,000 bbls. of eggs. The state carries on a considerable foreign commerce through the ports of Toledo, Cuyahoga (Cleveland), and Sandusky on Lake Erie, and Cincinnati on the Ohio. During the year ending June 30, 1859, the exports amounted to \$268,011, \$147,057 being in American and \$115,954 in foreign vessels, and the imports to \$267,846, \$196,031 being in American and \$71,815 in foreign vessels. The clearances were 226 American vessels, tonnage 38,058, and 190 foreign vessels, tonnage 22,832—total, 416 vessels, tonnage 60,890; and the entrances were 238 American vessels, tonnage 39,824, and 209 foreign vessels, tonnage 23,605—total, 447 vessels, tonnage 63,429. The tonnage of the state was 125,067, of which 6,548 was registered and 118,509 enrolled and licensed. During the year 52 vessels were built, having an aggregate capacity of 8,580 tons. Of these, 19 were steamers and 28 sloops and canal boats. In addition to a good system of turnpike roads, Ohio has 4 canals constructed by the state, viz.: the Ohio, from Portsmouth at the mouth of the Scioto to Cleveland on Lake Erie; the Miami, from Cincinnati to Toledo; the Hocking, in the valley of the Hocking river; and the Muskingum improvement in connection with the Muskingum river; and there are two canals built by incorporated companies, viz.: the Sandy and Beaver and the Ohio and Pennsylvania. The aggregate length of canals and river improvements is 849 m.; of turnpike and plank roads, 3,100 m.; of common roads, 67,000 m. The railroads lying wholly or partly in the state, in 1858, as reported by the commissioner of statistics, were as follows:

Name.	Terminal.	Length in miles.	Aggregate cost.
Bellefontaine and Indiana.....	Gallion and Union City.....	118	\$3,180,694
Central Ohio.....	Wheeling and Columbus.....	141	6,687,287
Cincinnati, Hamilton, and Dayton.....	Dayton and Cincinnati.....	60	3,682,800
Cincinnati, Wilmington, and Zanesville.....	Zanesville and Morrow.....	181	6,250,841

* Nearly finished to Union City, 80 miles further.

Of these roads 2,983 m. were within the state limits. Their aggregate capital paid in amounts to \$70,638,215. The management of the canals and similar public works is intrusted to

a board o. works consisting of 8 members, one elected annually for 3 years. The estimated cost of the public works at the time of their completion was \$14,627,549; and the net expense of maintaining them for the 5 years ending with 1860, has been annually a little less than $\frac{1}{4}$ of 1 per cent. on this cost, as shown in the subjoined table:

Years.	Receipts.	Expenditures.	Excess of expenditures.
1856.....	\$494,767	\$495,479	\$70,712
1857.....	845,720	863,937	18,267
1858.....	297,854	373,524	75,170
1859.....	257,520	363,606	105,796
1860.....	308,985	385,899	76,964

—The banking system of Ohio comprises the state bank (a nominal institution) with 36 branches, having in Nov. 1860 a capital of \$4,104,500 and a circulation of \$7,408,659; 7 independent banks, capital \$632,264, circulation \$575,685; and 11 free banks, capital \$1,124,600, circulation \$655,248. Total capital, \$5,861,364; total circulation, \$8,634,887.—The present constitution of Ohio was adopted in 1851. The right to vote is secured to every white male citizen of the United States 21 years of age, who has resided in the state one year next preceding the election. The general elections are held every 2 years on the 2d Tuesday of October. The general assembly consists of a senate of 35 members and a house of representatives of 100 members, both elected in districts for 2 years. The executive officers are a governor chosen for 2 years (salary \$1,800), lieutenant-governor (\$2 a day during the session of the legislature as president of the senate), secretary of state (\$1,400), auditor (\$1,600), treasurer (\$1,500), comptroller of the treasury (\$1,200), attorney-general (\$1,400), and commissioner of schools (\$1,500). The judiciary comprises a supreme court of 5 judges chosen by the people for 5 years, one every year, having original jurisdiction in quo warranto, mandamus, habeas corpus, and procedendo, and appellate jurisdiction in other matters; and 43 judges of common pleas, elected for 5 years. The state is divided into 10 common pleas districts, each of which is subdivided into 3 parts, each part electing one or more of the judges. Courts of common pleas are held by one or more of the judges in each county, and district courts by the common pleas judges of each district, with one judge of the supreme court. There are also superior courts of Cincinnati, Montgomery co. (Dayton), and Franklin co. (Columbus); probate courts in every county, and justices' courts in every township of the state. The judges of the supreme court receive a salary of \$1,700 each, of the courts of common pleas \$1,500, of the superior court of Cincinnati \$3,500, and of the superior courts of Montgomery and Franklin cos. \$1,500. The receipts and expenditures of the state during the financial year ending Nov. 15, 1860, according to the governor's annual message, were as follows:

Sources.	Receipts.	Disbursements.
General revenue.....	\$305,792 40	\$301,223 58
Sinking fund.....	1,364,664 18	1,349,885 66
Canal fund.....	431,874 62	417,125 54
Common school fund.....	1,283,596 72	1,250,838 17
School library fund.....	82,719 78	73,895 71
National road fund.....	14,061 88	14,045 81
Three per cent. fund.....	19 04
Total.....	\$3,977,718 13	\$3,911,508 97

Leaving a balance in the treasury of \$66,209.15. The value of real estate in 1860 was \$639,894,811; value of personal estate, \$248,408,290; total value of taxable property, \$888,302,601; increase in one year in the value of real estate not in cities and villages, \$54,158,987; decrease in the value of real estate in cities and villages, \$8,878,680; net increase in the value of real estate, \$45,780,307; decrease in the value of personal property, \$3,387,657; net increase in the value of taxable property, \$42,392,650. The state levy for all purposes is 89 $\frac{1}{4}$ cents on \$100 of valuation, making for 1861 \$3,503,712.93, and the local taxes for the same year amount to \$7,318,968.41; the total amount of tax levy for 1861 being therefore \$10,817,676.34. The state debt in 1860 was: foreign, \$13,978,023.53; domestic, \$277,210.36; irreducible, \$2,677,600.32; total, \$16,927,834.21.—The public institutions of Ohio, with their statistics in Nov. 1858, are the following:

Name.	Location.	Date of opening.	No. of inmates.	Annual expenses.
Central Lun'c Asylum	Columbus..	1853	570	\$100,698
Northern " "	Newburg..	1855		
Southern " "	Dayton....	1855		
Hamilton co.	" "	" "	150	21,423
Deaf and Dumb	Columbus..	1829	100	16,000
Inst'n for the Blind	" "	1837	26	17,150*
Asylum for Idiots and Imbecile Youths...	" "	1837	693
Penitentiary	Lancaster.	1838	120†
Reform schools	Fairfield co.	1858	120†

The number of convicts in the penitentiary, Nov. 1, 1860, was 932. The actual expenditures during the year were \$97,610, and the earnings \$97,905, leaving a balance in favor of the prison of \$295. Each prisoner under the age of 21 and without a common English education receives 3 hours' teaching a day, and each prisoner over 21 one hour's teaching. Corporal punishments are not used, the penalty for disorderly conduct being solitary confinement. Regular good conduct shortens the term of imprisonment. The number of paupers supported by the state in 1859 was 15,148; and the number of criminals convicted was 1,495, exclusive of 8,567 police offences in cities. According to the report of the commissioner of statistics in 1860, there were 5,237 churches in Ohio, viz.: 584 Baptist, 305 'Disciples', 83 Episcopal, 75 Evangelists', 98 Friends', 516 Lutheran, 1,915 Methodist, 877 Presbyterian, 190 Roman Catholic, 308 United Brethren's,

* Over and above \$62,700 earned by the convicts.

† In Nov. 1859.

68 Universalist, and 228 of minor denominations.—The state has always devoted great attention to education. The school fund consists of the proceeds of the congressional grant to the territory of every 36th section of land for common schools, and of two townships, comprising 69,120 acres, for the establishment of colleges. The state also levies a tax for school purposes, and there are local taxes by townships for sustaining high schools, for buildings, &c. During the year ending Aug. 31, 1860, the receipts and expenditures were as follows:

RECEIPTS.	
Balance on hand, Sept. 1, 1859.....	\$582,790 57
Fines, licenses, and miscellaneous sources.....	69,775 13
Irreducible school funds.....	170,640 45
State tax.....	1,944,155 89
Local taxes.....	1,482,589 99
Total.....	\$3,506,901 58
EXPENDITURES.	
Teachers' salaries.....	\$2,046,000 92
Sites, buildings, and repairs.....	457,543 31
Fuel, and all other contingent expenses.....	257,125 44
Total.....	\$2,760,669 67

The value of school houses in 1855 was \$2,229,911; in 1859, \$4,409,122; in 1860, \$4,707,227. In 1860 the number of school houses was 10,422; public high schools, 161; pupils enrolled in schools, 685,177; average daily attendance, 405,592; teachers employed, 20,731; pupils enrolled in high schools, 13,183; teachers employed, 819. In addition to these are the following institutions:

Character.	Institutions.	Teachers.	Pupils.
Theological.....	11	38	209
Legal.....	2	5	60
Medical.....	10	60	1,110
Commercial.....	10	20	800
Academies and seminaries.....	90	404	8,231
Private and parochial schools.....	185	316	16,139
Universities and colleges.....	22	139	8,878

The principal collegiate institutions with their dates of foundation are: the Ohio university, at Athens, 1804; Miami university, at Oxford, 1824; Franklin college, at New Athens, 1824; Western Reserve college, at Hudson, 1826; Kenyon college, at Gambier, 1826; Denison college, at Granville, 1832; Oberlin college, at Oberlin, 1834; Marietta college, at Marietta, 1835; St. Xavier college, at Cincinnati, 1840; Wittenberg college, at Springfield, 1845; Urbana university, at Urbana, 1850; Antioch college, at Yellow Springs, 1852; the Ohio Wesleyan university, at Delaware, 1854; the theological department of Kenyon college, 1827; Lane theological seminary, at Cincinnati, 1829; theological departments of Western Reserve college, 1830; of Denison college, 1832; of Oberlin college, 1835; theological seminary of the Associate Reformed church, at Oxford, 1839; Wittenberg theological seminary, 1845; biblical department of Ohio Wesleyan university, 1849; law school of Cincinnati college, at Cincinnati, 1833; medical college of Ohio, at Cincinnati, 1819; medical department of Western Reserve college, at Cleveland, 1844; Star-

ling medical college, at Columbus, 1847; western college of homœopathic medicine, at Cleveland, 1850. There are many well endowed female colleges. A tax of $\frac{1}{10}$ of a mill for school libraries was suspended in 1857, but resumed in 1858, and amounted to \$83,920. Exclusive of the school libraries, there are in the state collections and various literary institutions about 150,000 volumes. The state library was established in 1817, and the entire expenditures for its increase and management up to Nov. 15, 1860, were \$58,543. The number of volumes is 22,798. The public press in 1850 comprised 261 periodicals, circulating 80,000,000 copies annually. Of these, 26 appeared daily, 10 semi-weekly or tri-weekly, 201 weekly, 23 semi-monthly or monthly, and 1 quarterly.—The first explorations in the territory which now constitutes the state of Ohio were made by the French, the discoveries of La Salle in this region dating from about 1680. The object of the French adventurers, however, seems to have been trade rather than settlement. They were soon involved in disputes with the English, who, having obtained from their sovereign a grant covering part of the territory claimed by the French, sent out surveyors, and established trading posts in the Ohio valley. It was in the war which broke out in consequence of these conflicting claims that Washington first became known; but neither his abilities nor the operations of a powerful force sent out under Gen. Braddock could overcome the French, who kept possession of the country until Canada and the whole country W. to the Mississippi were surrendered by the treaty of 1763. After the war of the revolution disputes arose between several of the states respecting the right of soil in this territory, which were only allayed by the cession of the whole to the United States, Virginia reserving 3,709,848 acres near the rapids of the Ohio for her state troops, and Connecticut a tract of 3,666,921 acres near Lake Erie. In 1800 jurisdiction over these two tracts was relinquished to the federal government, the states retaining the right to the soil, and disposing of it in small lots to settlers (from which sales Connecticut obtained her magnificent school fund), while the Indian titles to the rest of the state were bought up by the general government. In 1787 congress undertook the government, and in 1788 the first permanent settlement was made at Marietta. The first years of the North-West territory, as it was called, were harassed by Indian warfare, which was not terminated until after the signal victory of Gen. Wayne in 1794. In 1799 the North-West territory was organized, and shortly afterward Ohio formed into a separate government. It was admitted into the Union as a state in 1803.

OHIO. I. A N. W. co. of Va., bounded E. by Pennsylvania and W. by the Ohio river, and drained by Wheeling and other small creeks; area, 140 sq. m.; pop. in 1850, 18,006, of whom 164 were slaves. Its surface is hilly and its

soil fertile, especially along the Ohio. Most of the land is well adapted to pasturage. Mines of bituminous coal are found among the hills and are extensively worked. The productions in 1850 were 214,020 bushels of Indian corn, 57,709 of wheat, 76,767 of oats, 4,111 tons of hay, 98,590 lbs. of wool, and 104,722 of butter. There were 9 grist mills, 8 saw mills, 4 iron foundries, 2 cotton, 1 woollen, 8 nail, and 5 glass factories, 17 collieries, 8 paper and 2 planing mills, 15 churches, and 8,529 pupils attending public schools. The value of real estate in 1856 was \$5,101,088, showing an increase of 26 per cent. since 1850. Capital, Wheeling. II. A W. co. of Ky., bordered on the S. by Green river which is here navigable by steamboats, and intersected by Rough creek; area, about 500 sq. m.; pop. in 1850, 9,749, of whom 1,182 were slaves. It has an undulating surface and a fertile soil, and contains iron ore and coal. The productions in 1850 were 521,128 bushels of Indian corn, 10,607 of wheat, 18,780 of oats, 1,543,692 lbs. of tobacco, and 22,555 of wool. There were 10 grist mills, 5 saw mills, 6 tanneries, 28 churches, and 899 pupils attending public schools. Capital, Hartford. III. A S. E. co. of Ind., separated from Kentucky on the E. by the Ohio river, and bounded N. W. by Laughery creek; area, about 90 sq. m., being the smallest county in the state; pop. in 1860, 5,475. The surface is considerably diversified, rising in some places into high hills, but it is only in very few places that it is too much broken for cultivation. The soil, resting mainly on blue limestone, is fertile both on the hills and in the bottom lands. The productions in 1850 were 269,085 bushels of Indian corn, 45,479 of wheat, 9,718 of oats, 2,023 tons of hay, and 5,801 lbs. of wool. There were 2 saw mills, 2 tanneries, 15 churches, and 2,022 public school pupils. Capital, Rising Sun.

OHIO RIVER, the largest branch of the Mississippi river from the east, known to the early French settlers as *la belle rivière*, and famed for the uniform smoothness of its current as well as for the beauty and fertility of its valley. It is formed in the W. part of Pennsylvania by the junction at Pittsburg of the Monongahela and Alleghany rivers. By the latter the drainage valley of the Mississippi is extended into the southern part of the state of New York, and in Potter co., Penn., reaches a point where over an extent of a few acres it is a mere chance whether the water that falls upon the surface reaches the ocean by the gulf of Mexico, the gulf of St. Lawrence, or Chesapeake bay. The course of the Ohio and of all its tributaries, from their sources W. of the Alleghanies to the outlet of the river in the Mississippi, is through a region of stratified rocks, little disturbed from the horizontal position in which they were deposited, and nowhere intruded upon by uplifts of the azoic formations, such as in other regions impart grandeur to the scenery and variety to the valleys of the rivers. Over an area of drainage

of the Ohio and its branches estimated at 202,400 square miles, the topography is uniform in its principal features, and, though often beautiful, still for the most part tame. The valleys are depressions below the general summit level of the country; all of them were eroded by currents of water, and the piles of strata presenting no portions that could resist the action of these, the descent of the river beds is gentle, with no sudden breaks or precipitous falls. The banks, however, are often steep, and in many places, especially upon the smaller rivers, the waters have worn a narrow passage between vertical cliffs of limestone to the depth of several hundred feet from their summits. Generally the rivers spread out to considerable width, and in dry seasons become shoal to the serious impediment of navigation. An interesting feature in the banks of the river is the succession of terraces often noticed rising one above another at different elevations, and sometimes spreading out in broad alluvial flats. Though they are often 75 feet or more above the present mean level of the river, they were evidently formed by fluvial deposits made in distant periods, when the river flowed at these higher levels. Evidence is altogether wanting to fix the date of these periods. Upon the lower branches of the river, at the level of present high water, are mounds and earth works wonderful in their numbers and extent, which were constructed, as far as can be ascertained from various proofs, full 2,000 years since, the fact being thus established that the river must have flowed at its present level at least so far back. The city of Cincinnati stands upon two of these terraces, the upper one 60 feet above the lower, and this 60 feet above low water of the river. In the gravel of the upper one have been found the teeth of an extinct species of elephant. Shells which have been found at corresponding elevations are of recent species, such as are still common to the waters in the neighborhood.—The total length of the Ohio river is about 950 m.; but from Pittsburg to the mouth of the river in a straight line it is only about $\frac{1}{3}$ of that distance. Its course till it passes out of Pennsylvania is a little W. of N. to Beaver, and thence W. to the line of the state of Ohio. It then flows S. between Ohio and Virginia, passing Wheeling, the W. terminus of the Baltimore and Ohio railroad, 92 m. below Pittsburg. The general course of the river is W. S. W. After passing between Ohio and Virginia, it borders the whole length of Kentucky, separating that state from Ohio, Indiana, and Illinois on the N. The width of the river varies from 1,200 to 4,000 feet. Its depth at different seasons is very fluctuating, the range between high and low water being often 50 and sometimes 60 feet. During portions of the summer season and in the autumn, when the water is low, the larger steamboats ascend no further than Wheeling, and even below this point they pass with difficulty, or are arrested

by the sand bars, which, with the low sandy islands, called tow heads, badly obstruct the navigation. At the lowest stage the river may be forded at several places above Cincinnati. In the winter it is often frozen over, and for several weeks floating ice prevents its navigation. The rate of its current varies with the stage of the water from 1 to 8 m. an hour. The only rapids are at Louisville, and these are not insurmountable to all the steamboats. In 2½ m. the fall is about 22 feet. A canal was long since constructed past these rapids at Louisville, but being only 16 feet deep it is not sufficiently capacious for the largest boats. —The country bordering the Ohio is for the most part a thriving agricultural region, and many prosperous towns and cities have grown up within the present century on its banks. Manufactures are encouraged by the mines of coal and iron ore that abound in the country traversed by this river and its tributaries, and the products of these add largely to the immense transportation carried on by the boats. The character and extent of these operations are particularly noticed in the descriptions of the several states and large towns on the borders of the river. (See also COAL, and IRON.) —The tributaries of the Ohio from both sides are numerous, and many of them are important rivers, as the Muskingum, Scioto, and Miami of Ohio, the Wabash of Indiana and Illinois, the Sandy, Kentucky, Green, Cumberland, and Tennessee of Kentucky.

OIDIUM ALBICANS. See EPIPHYTES, vol. vii. p. 246.

OIL BIRD. See GUACHARO.

OIL CLOTH. See FLOOR CLOTH.

OIL OF BRICK, an oily preparation used by lapidaries as a vehicle for the emery by which stones are cut. It is made by distilling from a brick the oil in which it has been soaked, and collecting the product.

OIL OF VITRIOL. See SULPHURIC ACID.

OILS (Lat. *oleum*), a class of fatty substances existing in various parts of vegetable and animal bodies, sometimes in a solid form, when they are commonly known as fats, and again in a fluid state, when they are called oils; the fats, however, by increase of temperature become fluid, and most of the oils by increased cold assume in part a solid consistency. The fats are comparatively rare in plants, and abound in warm-blooded animals; but fish and cold-blooded animals produce oils. In plants oil abounds most in the fruits, and especially in the dicotyledonous seeds; and it may generally be separated from the cells of the tissue by simple pressure. Heat may be applied to the bruised seeds to facilitate the separation by making the oil more fluid; and in case of its existing in the form of vegetable fat, boiling the portions of the plant that contain it in water causes the oil to separate and rise upon the surface in a scum, which becomes solid on cooling. By destructive distillation of vegetable matters, and even of the bituminous coals and

shales derived from them, the elements hydrogen and carbon may be made to unite to form oils of the class called carbohydrogens or hydrocarbons; and such are elaborated upon a great scale by nature, as is seen in the oil wells of different parts of the world. (See CARBOHYDROGENS, and PETROLEUM.) Beside this class of oils are the two great groups of the fixed and the volatile or essential oils. The former are distinguished by their not evaporating until the temperature is raised to about 500° F., or nearly to their boiling point; and then they give off vapors which are not condensable into oil again, but are new products derived from the decomposition of the oil. The volatile oils readily evaporate, and are generally obtained by distilling with water the substances in which they exist. By ultimate analysis the fixed and most of the volatile oils are reduced to the elements carbon, hydrogen, and oxygen, the proportions of which are not very different in the different oils, ranging generally from 74 to 80 per cent. of carbon, 10 to 18 of hydrogen, and 9 to 12 of oxygen. Nitrogen when detected is supposed to be derived from impurities. In their proximate composition the fats and oils are mixtures of three substances of similar properties; two of them at ordinary temperatures are solid, and are called stearine and margarine, which are themselves compounds respectively of stearic and margaric acids with glycerine; and the third is a fluid body called oleine, also a compound of glycerine with oleic acid. The last named, according to the proportion in which it is present, gives softness and fluidity to the compound. Mutton fat contains a large proportion of the solid ingredients, and the liquid oils are chiefly composed of oleine. The solid ingredients make their appearance in these when they are exposed to cold, as when castor and olive oils become thick in winter, and deposit a white substance beneath the liquid oleine. Hence the difference between winter-strained and summer-strained oils, the latter necessarily retaining more of the stearine and less of the pure oil. The following are some of the marked properties that distinguish the fatty oils, not including the hydrocarbons. They are bodies which leave upon paper a greasy stain, rendering it semi-transparent. In a liquid state, when pure, they are clear and transparent, and sometimes slightly viscid. They are colorless, or if tinged with yellow this disappears by bleaching in the sunlight or by treatment with animal charcoal. If they have a taste or odor, it is owing to the presence in minute quantities of certain acids peculiar to the body from which they are derived. Their specific gravity at ordinary temperatures is for the most part included between .918 and .970; this varies greatly with the temperature of the substance; thus castor oil at 58° has a density of .970, and at 200° it is only .908. They congeal at various temperatures, olive oil at about 82° F. and almond oil at —18°. They are highly

inflammable, and their chief use is for illuminating purposes, being used either in the liquid form or in candles prepared from their solid ingredients. (See CANDLE.) Exposed to the air, some of the oils absorb oxygen, thicken, and are finally converted into a solid substance; these are used to mix with paint to hasten its drying and give it solidity. (See DRYING OILS, and LINSEED OIL.) When such oils are scattered even in very small quantity upon heaps of vegetable fibre, as hemp, cotton, paper, or straw, the absorption of oxygen goes on rapidly, especially in a warm place or in the sunlight, and the chemical action is liable to generate heat sufficient to set the mass on fire. Thus have occurred many cases of spontaneous combustion. (See COMBUSTION, SPONTANEOUS.) Their drying property is greatly increased by heating them with about $\frac{1}{10}$ of their weight of litharge, which is dissolved in the oil. The oxide of manganese may be used for the same purpose. Linseed oil thus treated is called boiled oil. Another class of oils by exposure thicken and become acid and rancid, emitting an offensive odor. This is owing to their containing mucilaginous and albuminous matters, which decay and react on the oil, setting free the fatty acids and decomposing the glycerine. By removing the mucilaginous matters in the process of purifying the oils, this change may be prevented. When the fat oils are mixed with water, the two fluids soon separate, the oil rising upon the surface of the water. Some of the impurities of the oils may be separated by shaking the two liquids together, when they remain with the water. Ether, oil of turpentine, and benzole particularly are solvents of oil, and the last named has recently come into use for removing greasy stains from fabrics. In alcohol the fatty oils are soluble only to a certain extent. Ammonia unites with them, forming a soapy liquid, called volatile liniment, used in medicine as a rubefacient. When heated with potash or soda the fatty bodies are decomposed, their acids uniting with the alkali, and the glycerine base being set free. This is the process called saponification or soap making, and the soap is the compound of the acids of the fat with the alkali introduced. (See SOAP, and GLYCERINE.) Beside the uses already named for oils, they are employed in manufactures for dressing cloth, and for lubricating machinery. (See LUBRICANTS.) In medicine a great number obtained from as many different sources are variously exhibited, both externally in different preparations, and also internally.—Most of the important oils are described under their own names in this work, together with the manner of collecting and using them.

OINTMENT, in pharmacy, a mixture of fatty and waxy substances of the consistency of butter, used as a dressing for sores, blisters, &c., and also as a vehicle for the application of other substances as rubefacients or caustics. To preserve the whiteness of lard ointments, as well as to prevent their becoming rancid, it

is recommended to add 4 parts by weight of powdered benzoin to each 100 parts of melted fresh lard. This also protects the lard from the action of any alkaline ingredients of the ointment. The infusion of $\frac{1}{4}$ part of poplar buds in the ointment causes it to resist oxidation.

OISE, a department in the N. E. of France, formed from parts of the old provinces of Isle de France and Picardy, and bounded N. by Somme, E. by Aisne, S. by Seine-et-Marne and Seine-et-Oise, and W. by Eure and Seine-Inférieure; area 2,218 sq. m.; pop. in 1856, 396,085. The chief rivers are the Oise, from which the department is named, and its tributaries the Serre, Lette, Aisne, and Nonette, all of which join it from the left. Beside these, the Epte passes through the W. and the Ourcq through the S. E. The surface is low and undulating, and the soil consists in general of strong clay, but there are sandy barrens. The wine produced is of inferior quality, and the vineyards are decreasing. Woollens, linen, canvas, beet root sugar, &c., are manufactured. The Oise, Aisne, and Ourcq are navigable in the department for 82 m.; there are two canals having a total length of 21 m.; and a railway traverses the department for 43 m. Capital, Beauvais.

OISE (anc. *Isara*), a river of France, which rises in the province of Hainaut in Belgium, near the French frontier, flows S. W. through the departments of Nord, Aisne, Oise, and Seine-et-Oise, and joins the Seine on the right bank, 12 m. below Paris, after a course of about 140 m. Its principal tributaries are the Noirieu, Brèche, and Thérain on the right, and the Ton, Serre, Lette, Aisne, Autonne, and Nonette on the left. The Oise communicates by canals with the Somme, the Sambre, and the Scheldt.

OJIBWAYS. See CHIPPEWAS.

OKA, a river of central Russia, one of the principal tributaries of the Volga. It rises about 40 m. S. W. from Orel, in the government of the same name, passes that town, and flowing with a swift current N., N. E., S. E., and N. E. through the governments of Tula, Kalooga, Moscow, Riazan, Tambov, Vladimir, and Nijni-Novgorod, joins the Volga at the town of Nijni-Novgorod. Its total course is 650 m., for almost the whole of which it is navigable. It has several considerable tributaries. The Ivanovska canal connects it with the Don.

O'KEEFFE, JOHN, an Irish dramatist, born in Dublin, June 24, 1747, died in 1838. He was originally designed for a painter, but early turned his attention to dramatic composition and acting, and at the age of 15 wrote a comedy. Having obtained an engagement at the Dublin theatre, he acted there and in adjoining towns for 12 years. About 1780 he went to London, but, failing of employment as an actor, applied himself to writing, and between 1781 and 1798 composed nearly 50 comedies, comic operas, and farces. Several of these were very popular, especially "The Castle of Andalusia,"

"Wild Oats," "The Poor Soldier," "The Young Quaker," and "Peeping Tom." In his 50th year O'Keeffe became blind. In 1826 he published his "Recollections, or Autobiographical Memoirs."

OKEN, LORENZ, a German naturalist, the founder of the transcendental or physio-philosophical school of natural science, born in Bohlsbach, Württemberg, Aug. 1, 1779, died in Zürich, Aug. 11, 1851. His real name was Lorenz Ockenfuss, which he abridged to Oken when he became a private teacher at Göttingen, having previously studied natural history and medicine at the university of Würzburg. In 1802 he published his *Grundriss der Natur-Philosophie* (8vo., Frankfurt), in which he reduced to a system the materials which Fichte and Schelling had previously undertaken, but with little success, to arrange; in this he maintained that animal classes are simply a representation of the organs of sense, and divided the animal kingdom accordingly into 5 classes. In *Die Zeugung* (Frankfort, 1806) he advanced the doctrine that all organic beings originate from and consist of vesicles or cells, remarkably agreeing with the results of recent microscopical science. In his *Beiträge zur vergleichenden Zoologie, Anatomie und Physiologie* (Würzburg, 1806) he demonstrated that the intestines originate from the umbilical vesicle, and that this corresponds to the vitellus or yolk bag, which C. F. Wolff had before proved in the chick; he in the same work described the *corpora Wolffiana* or primordial kidneys. In 1807 he accepted the appointment of extraordinary professor of the medical sciences in the university of Jena, giving for his inaugural discourse the famous essay *Ueber die Bedeutung der Schädelknochen*, or "On the Signification of the Bones of the Skull;" the origin of this idea of the cranial vertebrae, and the other doctrines above alluded to, may be found in the articles COMPARATIVE ANATOMY and PHILOSOPHICAL ANATOMY. This lecture was delivered in the presence of Goethe, from whom Oken has been most unjustly accused of borrowing its central idea; for an account of the controversy on this subject, and for a complete vindication of Oken, see the sketch of his life by Owen in the "Encyclopædia Britannica" (1858). Oken's lectures at Jena embraced almost every department of natural science, and were highly esteemed. In 1808 he announced the propositions that organism is a combination of the activities of the universe within a single individual body, and that world and organism are one in kind; that light is only a polar tension of the ether evoked by a central body in antagonism with the planets, and heat only the motion of this ether—thus anticipating the doctrine of the correlation of physical forces. He extended his system also to the mineral world. The 1st edition of his *Lehrbuch der Naturphilosophie* was published in 1809-'11, a 2d in 1831, and a 3d in 1843; the last was translated into English by Dr. Tulk (London, published

by the Ray society, 1847). In 1810 he was made court councillor, and in 1812 ordinary professor of natural sciences at Jena. In 1816 he commenced the publication of his celebrated periodical, the *Isis*, devoted principally to natural science, but occasionally commenting on the politics of the German states; the criticisms on the latter led to complaints, and the court of Weimar required him either to suppress the *Isis* or to resign his professorship; he chose the latter alternative, and published his journal (prohibited at Weimar) at Rudolstadt uninterruptedly until 1848. A further attempt was made to crush his independent spirit by accusing him of being a member of a forbidden secret democratic society; he was tried and acquitted, and thereupon retired to private life, occupying himself with his scientific pursuits, and publishing several important works, beside his numerous contributions in the *Isis*. In 1821 he originated the annual general meetings of German naturalists in different cities, the first of which was held at Leipsic in 1822, and which have been continued to the present time; the British and American associations for the advancement of science have been since then instituted more or less after the German model. In 1828 he resumed his occupation of private teacher in the newly established university at Munich, and was soon after appointed professor in the same. In 1832, on the proposition of the Bavarian government to transfer him to a provincial university, he resigned his appointments and left the kingdom; he retired to Switzerland, and in 1833 was appointed professor of natural history in the recently established university of Zürich, which position he retained, contributing largely to his favorite science, until his death. A statue has been erected in his honor in the university of Jena. His views on philosophical anatomy, as illustrating the all-in-all and the all-in-every-part, will be found under that title.

OKHOTSK, a Russian province of eastern Siberia; pop. about 7,000. It is a narrow tract along the shore of the sea of Okhotsk, from 80 to 200 m. broad and about 1,000 m. long. Its coast line is indented by several arms of the sea, and its interior is traversed nearly throughout its length by the chain of the Stanovoi mountains. The climate is severe, but there are large tracts of heathy pasture and scattered clumps of trees, chiefly of alder and birch, frequented by numerous animals valuable for their furs. The coasts are well supplied with fish. The only domestic animals are reindeer and dogs. The territory is chiefly used as a penal settlement for the most hardened offenders, and the inhabitants consist for the most part of them or their descendants.—OKHOTSK, a town in the above province, is situated on a narrow tongue of land projecting into the sea, at the mouths of the Okhota and Kukhtui rivers, lat. 59° 21' N., long. 142° 45' E.; pop. 957. It consists of a collection of ill built log houses, standing on a low shingly beach; there are a

government house, hospital, church, and storehouses. It is a station of the Russo-American trading company, who bring furs hither from America, on their way to Kiakhta to exchange for Chinese goods. There is a yard for repairing ships, but the harbor is very inferior.

OKHOTSK, SEA OF, an arm of the N. Pacific ocean, between Kamchatka and Siberia. It is about 1,000 m. long and 500 broad, and contains several islands, the largest of which, Saghalien, is situated near its S. W. shore. There are numerous gulfs in this sea, and several rivers fall into it, the greatest of which is the Amoor. The shores are covered with ice from November to April, but the main expanse continues open throughout the year. It is generally deep, without shoal or sand bank, and is subject to fogs and storms. The sea of Okhotak is annually visited by numbers of American whale ships, in pursuit of whales, which are sometimes found here in great abundance.

OKRA (*Abelmoschus esculentus*, Wight and Arnott), a plant, the unripe pods of which are used in some parts of the United States as a vegetable, being sliced and added to soups to render them more glutinous. It is the same as the gombo of the West Indies, being there employed both for the thickening of soups and as a vegetable, or even for pickling like capers. Another species with similar properties is employed for the same purposes in the East Indies, both belonging to the natural order of *malvaceae*, the prevailing quality of which is mucilaginous. The okra has a smooth stem 4 to 5 feet high, cordate, 5-lobed, toothed leaves; deciduous, spathaceous, 10-bracted calyx, bursting on one side; pale yellowish flowers; and a 5-celled pod about 6 inches long, opening into 5 loculicidal valves, and filled with many roundish seeds, which when ripe and roasted are sometimes ground and used for coffee. The okra is raised by sowing the seeds from April till June, in drills an inch deep, dropping the seeds about 8 inches from one another, and earthing up the plants 2 or 3 times in the season.

OLAF, a saint and king of Norway, killed in battle, Aug. 31, 1030. He was the son of Harald Gränske, and grandson of the famous Harald the Fair-Haired, and was educated by Sigurd Syr, the chief of an upland district, who married the young prince's widowed mother. At the age of 12 Olaf was intrusted with the command of a piratical expedition to the British coasts, where he assisted the Anglo-Saxons in opposing the Danes; and at the age of 16 he had been engaged in 9 great battles. In the course of his career as a viking or sea rover, he was led to Sweden; and on one occasion, being blockaded by the Swedes within the Maelar lake, he effected his escape by cutting a canal to the sea. For the next two years he infested the shores of France and Spain; and at length returning to Norway during the absence of Eric, then engaged in the wars of Canute in England, he took possession of the throne (1014), to the great joy of the Chris-

tians, and soon rendered the kingdom independent of both Sweden and Denmark. In his zeal for the Christian faith, into which he had been baptized in infancy, he burned the heathen temples, erecting churches on the ruins, and marched through his dominions at the head of an army, compelling submission to the new faith. He forbade all piracy, and enforced his law so rigorously that, although the vikings were sons of his most powerful subjects, he punished the offenders with loss of life or limb. His severity could not fail to provoke rebellion. While engaged in quelling this, he was suddenly attacked in his capital, Drontheim, by Canute the Great of England and Denmark, who laid claim to the crown of Norway, landed an army at Drontheim, and effected an easy conquest of the kingdom. Olaf fled with his infant son Magnus to Russia; but two years afterward (1030), assisted by his wife's brother, the king of Sweden, he entered Norway from beyond the N. W. frontier, gave battle to the Danish faction near Drontheim, and fell in the thick of the fight, with most of his followers and kinsmen. The body of the king was discovered by one of his faithful adherents, and secretly buried. It was afterward disinterred and deposited in a chapel, which Olaf had built at Drontheim upon the ruins of the temple of Thor, and which was the foundation of the present cathedral. The spot upon which the king fell was long marked by a rude cross, which has been replaced by a monument erected by the society of northern antiquaries. The tomb and the battle field became the resort of pilgrims from all Europe, and miracles were reported as performed at his tomb.

OLAND, or OELAND, an island in the Baltic belonging to Sweden, from which it is separated by a narrow strait called Calmar sound; area, 600 sq. m.; pop. 33,000. The island contains several villages, of which Borgholm, the capital, is the chief. The E. shores are high and steep, and the W. low. The interior is diversified by sand hills, and in the N. there are a few small lakes. A great part of the surface is covered with fine forests; and a strip of land along the coast is cultivated. Cattle and sheep are extensively reared. Oland is famous for its breed of diminutive ponies. The people are chiefly employed in fishing and navigation. There is an alum mine which employs about 300 hands.

OLBERS, HEINRICH WILHELM MATTHIAS, a German physician and astronomer, born in Arbergen, near Bremen, Oct. 11, 1758, died in the latter place, March 2, 1840. His life was devoted to the practice of medicine and the study of astronomy, the latter of which he pursued in an observatory erected by himself in Bremen, which was at the time of its construction one of the most complete in Germany. His writings on either subject were few and of little importance in comparison with his observations, particularly in astronomy. A series of these on the comet of 1779 first brought

him into notice, and he subsequently discovered a method of calculating the orbits of comets, which was considered superior to those previously in use. By this method he computed the orbits of the comets of 1781, 1795, 1798, 1799, 1802, and of the great one of 1811. Of still greater importance were his investigations respecting the existence of the small planets whose orbits lie between Mars and Jupiter. Kepler had suggested that a planetary body might occupy this space; and with a view of verifying this suggestion by actual examination, an association of 24 astronomers including Olbers was formed, who divided up the zodiac among themselves for independent scrutiny. On Jan. 1, 1801, the small planet Ceres was discovered by Piazzi of Palermo, who was not a member of the association, moving in an orbit between Jupiter and Mars; and on March 28, 1802, Olbers discovered in the northern part of the constellation Virgo the planet Pallas, having a mean distance from the sun about the same as that of Ceres. This led Olbers to conjecture that they were fragments of a larger planet once existing there, and that probably other portions might be found moving in nearly the same orbit. He accordingly set himself to exploring carefully, every month, the two opposite regions of the heavens in which the orbits of the new planets intersected, and where he supposed the fragments of the shattered planet must pass. In Sept. 1804, M. Harding of Bremen accidentally discovered a 3d planet, Juno, the nodes of whose orbit were nearly coincident with those of Pallas. This confirmed Olbers in his hypothesis, and he continued his search with renewed ardor. Rarely has so bold a conjecture been so well rewarded; for on March 29, 1807, he discovered a 4th, Vesta. The additional asteroids since discovered seemed at first to confirm the hypothesis of Olbers, but it is now shown that such an origin is scarcely possible. In March, 1815, he discovered near Perseus a comet having no visible nucleus, and in 1826 published a dissertation on the possibility of a collision between a comet and the earth. He subsequently proposed a re-formation of the constellations and a revision of the nomenclature of the stars.

OLD MAN OF THE MOUNTAIN. See **BATENITES**.

OLD POINT COMFORT, a post village and watering place of Elizabeth City co., Va., situated on James river, at the entrance of Hampton roads, 12 m. N. of Norfolk. It is much resorted to in summer for sea bathing, and has commodious hotels. The point is a low, narrow, sandy neck of land, on the extremity of which is Fort Monroe, a formidable structure covering 60 acres of ground. A redoubt thrown forward from its N. W. bastion defends the strip of land which connects the point with the mainland. One mile S. from Fort Monroe, on the other side of the entrance to Hampton roads, an artificial island has been formed upon a mud bank originally covered

with 17 feet of water, and upon the foundation thus obtained a fort has been erected.

OLD RED SANDSTONE. See **GEOLOGY**.

OLD TOWN, a township of Penobscot co., Me., on the Penobscot river and on the Bangor, Old Town, and Milford railroad, 12 m. N. from Bangor, and 70 m. N. E. from Augusta; pop. in 1850, 8,087. It contains 4 villages, Upper Stillwater, Great Works, Pushaw, and Old Town. Its principal business is connected with the timber trade. A large boom was placed across the Penobscot some years ago at a cost of \$100,000, to prevent timber from floating out to sea. In 1855, 181,000,000 feet of timber was rafted, employing over 800 men, and at one time 600 acres of logs were in the boom. The town has a bank and 7 churches.

OLDCASTLE, **SIR JOHN**, Baron Cobham, an English reformer, born in the reign of Edward III., put to death Dec. 14, 1417. He acquired the title of baron through his wife, the granddaughter and heiress of Lord Cobham. He fought with distinction in France in the reigns of Henry IV. and Henry V., and was a favorite companion of the latter monarch. Having become a convert to the doctrines of Wycliffe, he employed himself in collecting, transcribing, and circulating them among the people. The rapid progress which the Wycliffite movement made was owing in a large measure to his influence, and Henry V. was more than once importuned to have him arrested for heresy, but refused out of personal regard for him. The king undertook to reason with him, but he found Oldcastle firm in his opinions. "Next to God," he said, "I profess obedience to my king; but as to the spiritual dominion of the pope, I can pay him no obedience." Henry's toleration could go no further. The nobleman was confined in the tower and condemned to the flames, but made his escape into Wales, and it was reported that 20,000 Lollards would rise in arms under his command. A bill of attainder was thereupon passed against him, a reward of 1,000 marks offered for his head, and exemption from taxes promised to any town that should secure him. He eluded capture for 4 years, but at last was discovered and carried to London, where he was hanged in chains on a gibbet in St. Giles's fields, and roasted to death by a fire kindled under him. He wrote "Twelve Conclusions addressed to the Parliament of England," beside several religious tracts and discourses.—See "Chronicle of the Examination and Death of Sir John Oldcastle," by Bishop Bale (London, 1554; reprinted, 1729).

OLDENBURG, a German grand duchy, comprising the following separate territories:

Division.	Area in sq. m.	Pop. in 1855.
Duchy of Oldenburg.....	2,125	287,188
Principality of Lübeck.....	170	21,685
" " Birkenfeld.....	148	85,486
Total.....	2,448	294,859

The duchy of Oldenburg is situated on the left bank of the river Weser, which forms its N. E. boundary. It is bounded N. by the North sea, a deep inlet of which forms the Jahde bay; and on the E., S., and W. it is surrounded by the territory of the kingdom of Hanover. The whole country is a perfect level, intersected by several rivers, none of which, with the exception of the Weser, are navigable. Of a number of lakes the largest and most picturesque is the Zwischenahmer sea. One seventh of the area consists of the most fertile bottom land, upon which all kinds of grain, fruit, potatoes, beans, peas, &c., thrive luxuriantly; the remainder of fair arable soil and pasture. Oldenburg is almost exclusively an agricultural country, and its industry is of no great importance. The principality of Lübeck is enclosed by the duchy of Holstein. It consists of the city of Eutin, and one borough and 82 villages grouped around the banks of the lake of Eutin. Up to 1802 it was an independent bishopric. The principality of Birkenfeld lies in the southern part of the Rhenish province of Prussia, on the left bank of the Rhine. (See **BIRKENFELD**.)—The grand duchy has a common constitution for its three component parts. In the committee of the whole of the German diet it casts one full vote; in the executive committee it casts a vote only in conjunction with the duchies of Anhalt and the principalities of Schwarzburg. Its peace establishment is 8,700 officers and men, forming, together with the quota of the three Hanse towns, the 8d brigade of the 2d division of the 10th army corps of the German federal army. The state debt is \$2,800,000. The revenue of the duchy of Oldenburg is \$650,000, and its expenditure \$700,000 (including its quota of the expenses of the general government of the grand duchy, which amounts to \$275,000). The movement of shipping in the grand duchy in 1859 was as follows: vessels entered, 8,818, tonnage 419,030, of which 8,079 vessels and 235,316 tons were foreign; vessels cleared, 8,894, tonnage 456,128, of which 8,122 vessels and 249,528 tons were foreign. The merchant shipping of the duchy in 1859 amounted to 632 vessels, with an aggregate burden of 70,434 tons.—The present territory of Oldenburg proper was originally inhabited by the Chauci, and was afterward overrun by the Saxons. In 1180 the counts of Oldenburg obtained their independence from the dukes of Saxony. In 1448 a son of the late count was elected king of Denmark. The Oldenburg line having become extinct, the country fell to Denmark in 1667. In 1773 Denmark exchanged it for the possessions and claims of the Holstein-Gottorp family in Schleswig-Holstein, and it became an independent state once more. Having been annexed to France in 1811, it regained its independence in 1813, and obtained some territorial accessions (including the principality of Birkenfeld) from the congress of Vienna, which also raised the prince to the rank of

grand duke. In consequence of the revolution of 1848 the people obtained a liberal constitution, which however was curtailed in 1852. The present grand duke, Peter, succeeded his father Feb. 27, 1858.

OLDHAM, a parliamentary borough and market town of Lancashire, England, situated on an elevation near the W. bank of the Medlock and the source of the Irk, 7 m. N. E. from Manchester, with which it communicates by railway and canal; pop. of the town in 1851, 52,820; of the parliamentary borough, including Chadderton, Crompton, and Royton, 72,357. Oldham is situated in the midst of a rich coal field, and owes its growth, which is comparatively recent, to its manufacturing facilities. It has a number of handsome churches and other public buildings; a blue coat school with an endowment of more than £100,000; a free grammar school; a lyceum, a mechanics' institute, and a subscription library. The principal branch of industry is cotton spinning, there being in the town and vicinity over 150 mills, mainly for this process. Fustians, velveteens, corduroys, hats, brass and iron castings, rope, leather, and other articles are also made.

OLDHAM, JOHN, an English satirical poet, born in Shipton, Gloucestershire, Aug. 9, 1653, died at Holme Pierpoint, Dec. 8, 1683. He was graduated at Oxford in 1674, was patronized by Lord Rochester, the earl of Dorset, and Sir Charles Sedley, went to London in 1681, and finally devoted himself to poetry and the pleasures of the town. He satirized the Jesuits, was called the "English Juvenal," and was eulogized by Dryden. A new edition of his "Poetical Works," edited by R. Bell, was published in London in 1854.

OLDMIXON, JOHN, an English author, born in 1673, died in London in 1742. After producing several unsuccessful plays, he turned his hand to political writing, and was rewarded by the whigs with the post of collector of the customs at the port of Bridgewater. In the interest of his party he compiled a "Critical History of England," "History of England during the Reigns of the House of Stuart," and "History of England during the Reigns of William and Mary, Anne, and George I.," which have little or no merit. He superintended the first edition of the collection of English historians which appeared under the name of Bishop Kennett. In his "Prose Essay on Criticism" and "Arts of Logic and Rhetoric" (an adaptation from Bonhours), he attacked Pope, who made him conspicuous in the "Dunciad."

OLÉRON (anc. *Oliarius*), an island of France, in the bay of Biscay, separated from the mainland by a strait which in its narrowest part is 1 m. wide, and lying opposite the mouth of the Charente, the N. W. point being in lat. 46° 3' N. and long. 1° 24' W.; greatest length 18 m., greatest breadth 7 m.; pop. 16,000. It belongs to the department of Charente-Inférieure, and possesses 5 ports, La Flotte, Saint Martin, La Conarde, Loix, and Ars, be-

side the towns of Château and Pierre d'Oléron, the former of which is fortified. Except on the W. side, where it is much exposed, the island is generally fertile, producing grain, vegetables, and wine. The inhabitants are engaged chiefly in ship building, salt making, and trade in salt, wine, brandy, and grain. The island was successively the property of the counts of Anjou, the dukes of Aquitaine, the English, the French crown, and the opposite contending parties in the wars of the league.

OLÉRON, LAWS OF. See LAW MERCHANT, vol. x. p. 357.

OLIN, STEPHEN, D.D., LL.D., an American clergyman, born in Addison co., Vt., March 7, 1797, died in Middletown, Conn., Aug. 16, 1851. He was graduated at Middlebury college, Vt., and having visited the South for the benefit of his health, was appointed president of the Abbeville seminary, S. C. He subsequently abandoned the study of law, to which he had begun to apply himself, and entered the ministry of the Methodist Episcopal church. He was admitted a member of the South Carolina conference in 1824, and for two years was stationed in Charleston, at the end of which time the state of his health obliged him to desist from preaching. In 1827 he had a supernumerary relation granted him, and was stationed at Athens, Ga. Being relieved entirely from ministerial labors in 1828, his health became partially restored, and he was readmitted into the Georgia conference and appointed professor in Franklin college. In 1833 he was transferred to the Virginia conference, and elected president of Randolph Macon college, where he remained until he sailed for Europe in hopes of recruiting his health by travel. His tour extended over western Europe, Egypt, and Palestine. In 1840 he returned to the United States somewhat improved in health, and in 1842 became president of the Wesleyan university at Middletown, Conn. He was an impressive preacher, and a prominent advocate of the evangelical alliance. He wrote "Travels in Egypt, Arabia Petrea, and the Holy Land" (2 vols. 8vo., New York, 1843), and "Greece and the Golden Horn" (8vo., New York, 1854). His "Works," comprising sermons, sketches, and addresses, appeared in 1852 (2 vols. 12mo., New York), and his "Life and Letters" in 1853 (2 vols. post 8vo.).

OLIPHANT, LAURENCE, an English author and traveller, born in 1832. He is the only son of Sir Anthony Oliphant, C. B., who is descended from an ancient Scottish family of distinction in Perthshire, and was appointed chief justice of Ceylon in 1838. Mr. Oliphant was educated in England, and at an early age went to Ceylon, where he made the acquaintance of Jung Bahadoor, the Nepalese ambassador to London, who visited Ceylon in 1850 on his way home, and was invited to accompany him to Catmandoo, the capital of Nepal. On his return from that country he published "A Journey to Katmandu" (London and New

York, 1859), a work remarkable for vivacity and for a maturity of thought scarcely to be expected from so youthful an author. He soon afterward came back from India, studied law at the university of Edinburgh, and was admitted to the bar in Scotland and subsequently in England. In the latter part of 1852 he visited Russia, descended the Volga, traversed the country of the Don Cossacks, and spent some time in the Crimea. His second work, "The Russian Shores of the Black Sea" (London, 1858), appearing on the eve of the Crimean war, was well received by the public, and passed through 4 editions in a few months. Mr. Oliphant was soon after appointed civil secretary to the earl of Elgin, then governor-general of Canada, and went to Quebec, where he was made superintendent of Indian affairs. He travelled extensively both in the United States and in Central America, and gave his impressions on the north-western states of the Union in "Minnesota, or the Far West" (London, 1855). He also published anonymously at this period a pamphlet entitled "The Coming Campaign," in which he gave his views upon the best mode of conducting the war with Russia. This work he republished in 1855, under the title of "The Trans-Caucasian Provinces the Proper Field of Operations for a Christian Army." After his return from America he went to Turkey, and as a correspondent of the press accompanied Omer Pasha in a campaign, of which he gave an account in "The Trans-Caucasian Campaign of Omer Pasha" (London, 1856). In 1857, when Lord Elgin was sent as minister plenipotentiary to China, Mr. Oliphant became his private secretary, and on his return published a "Narrative of the Earl of Elgin's Mission to China and Japan" (London and New York, 1860), an entertaining and instructive account not only of the embassy but of the manners and customs of the Chinese and Japanese. He has since been appointed secretary of legation to Japan. His latest work is "Patriots and Filibusters, or Incidents of Political and Exploratory Travel" (London, 1861). Beside his books of travel, Mr. Oliphant has contributed largely to "Blackwood's Magazine," the "Cornhill Magazine," &c.

OLIPHANT, MARGARET (WILSON), a Scottish authoress, born about 1820. She has gained a considerable reputation as a novel writer by the production of a number of tales of Scottish life, distinguished by truth of detail, pathos, and a skilful delineation of character. They include "Passages in the Life of Mrs. Margaret Maitland of Sunnyside" (1849), "Merklund" (1851), "Adam Græme of Mossgray" (1852), "Harry Muir" (1853), "Magdalen Hepburn" (1854), "Lilliesleaf" (1855), a sequel to the first mentioned, and "Zaidee," the scene of which is laid in England. She has also written two shorter tales, "Katie Stewart" and the "Quiet Heart."

OLIVAREZ, GASPARO DE GUZMAN, count, a Spanish statesman, born in Rome, Jan. 6, 1587,

died in Toro, July 12, 1645. His father was ambassador at the papal court of Sixtus V. He studied at the university of Salamanca, and through the influence of his uncle, the duke of Uceda, was appointed gentleman of the bed-chamber to the prince of Asturias, afterward Philip IV., who soon after his accession to the throne in 1621 bestowed upon Olivarez the title of duke of San Lucar, and appointed him minister in place of his uncle. The new minister proved a despotic ruler, dismissing some of the best servants of the state to make room for his own creatures, and curtailing government expenses only to obtain the means of gratifying his taste for pomp and splendor. He gave some encouragement to manufactures, and in his foreign policy aimed at reconquering the provinces which Spain had recently lost, and restoring the kingdom to her old supremacy in Europe; but in this attempt he had to encounter the superior skill of the French minister, Cardinal Richelieu. Availing himself of the expiration of the truce with Holland concluded in 1609, he reopened hostilities with the Dutch in 1621, and sent Spinola to attack them by land; but the success of this distinguished commander was counterbalanced by the Dutch victories at sea; the Spanish colonies were almost ruined, and the Dutch, assisted by French subsidies, stood their ground so manfully that their enemy was forced to retire from the contest. Meanwhile Spain had been obliged by a coalition between France, Savoy, Venice, and the pope, to which England finally adhered, to give up the Valtelline, which was secured to the Grisons. Olivarez, nevertheless, attempted to make her influence felt in Italy and Germany, while he fostered troubles and conspiracies in France; but in these attempts he signally failed. Spinola, harassed by an unsuccessful campaign in Italy and the reproaches of the Spanish court, died of grief; the Spanish troops sent to assist the Austrians in their struggle against the German Protestants, were worsted at nearly every point; and finally the flame of insurrection, fanned by Richelieu's intrigues, broke out within the Spanish dominions. The province of Catalonia rebelled in 1640, and invoked the assistance of the French; at the same time Portugal threw off the Spanish yoke, and elected Duke John of Braganza king. Olivarez attempted to make light of the latter event in announcing it to the king; but Philip now began to understand that Olivarez had brought his kingdom to the verge of ruin. When, at the end of two years, he saw that all exertions to recover Portugal were fruitless, and that the last attempt of his minister against Richelieu had failed in the abortive conspiracy of Cinq-Mars, he resolved to dismiss the man who in his name had misruled Spain for nearly 22 years (1621 to 1648). Olivarez was supplanted by his nephew, Don Luiz de Haro, as he himself had supplanted his uncle Uceda. Having published an indiscreet defence of his administration, he was banished to Toro.

OLIVE (*olea Europaea*, Linn.), a branchy, glaucous, evergreen tree, growing about 80 feet high, found wild in the south of Europe, but extensively cultivated, and yielding a very valuable oil. It belongs to the natural order of *oleacea*, comprising trees and shrubs, natives chiefly of the temperate latitudes, such as the ash, the lilac, fringe tree, &c. The wild olive has lanceolate, opposite, entire leaves, of a paler color beneath, flowers in short, axillary, compound racemes, 4-toothed calyx, and 4-cleft corolla. From this original type, cultivation has produced varieties and sub-varieties, similar to what are found in the apple and in other fruit trees. The cultivated olive is, however, said to have been brought from Asia into Spain and Italy, in which countries, as well as in all those bordering on the Mediterranean, it has been under culture from time immemorial. Mr. London cites 6 principal sorts, of which he distinguishes the long-leaved chiefly cultivated in France, and the broad-leaved in Spain. In some portions of Italy little else is cultivated, and immense olive groves cover the country. The olive tree has in all ages been held in high estimation. In early times a branch of it borne to the ark by the returning dove, signified to Noah that the waters on the face of the earth were subsiding. Among the Greeks and Romans wreaths of its leaves adorned the brows of conquerors, and it has ever been regarded as the symbol of peace. In the Holy Land and other parts of Syria olive trees abound, and attain to a great age. The fruit is a smooth oval plum of a green or violet color, with a fleshy pericarp, containing a hard nut. It is bitter and nauseous to the taste, but when pickled it loses these properties, and is highly esteemed and extensively used as an article of diet. The pickled olives are chiefly the unripe fruits of a sub-variety known as *pignola*, the *O. oblonga* of DuRoi; these are repeatedly steeped in water, to which some alkali is added to hasten the process, and then taken out and bottled in salt and water with or without an aromatic.—The soils best adapted to the growth of the olive tree are those found upon schistous calcareous declivities situated near the sea. The olive was introduced into the southern part of the United States nearly two centuries ago from Portugal and the Bermudas; and as it is less tender than the orange tree, there is reason to hope that the cultivation of it may be widely extended. Already some success has repaid the labors of those who have given their attention to this matter. The islands on the coast of Georgia and Florida, and the seaboard of South Carolina, are well suited to the cultivation of the olive. The olive tree is raised by sowing the seeds, from cuttings, which grow easily and readily, and from little swellings or knobs called *uvols*, which are excrescences upon the bark containing embryo buds. These are similar to bulbs, because they are capable of producing new plants. They are carefully separated from the trunk

and planted in the ground where intended to grow. Olive trees begin to bear when but 2 or 3 years old, but are not very productive until about 6 years old, when they are of great value. From this period they yield abundantly for many years, even after the trunk becomes quite hollow. One tree near Nice, not long since famous for its remarkable size and great longevity, is said to have measured 88 feet in circumference at the bottom of the trunk, and to have been recorded in 1516 as one of the oldest trees in the neighborhood. Another celebrated tree at Pescio was said to be 700 years old; and there are plantations supposed to have existed since the time of Pliny.—Unlike most other vegetable oils, which are obtained from the seeds of plants, olive oil is contained in the pericarp, and is carefully extracted from it before the seed is pressed. Sometimes the fruit is gathered before it is fully ripe; at others it is allowed to fall from the trees. In the latter case there is danger of its being bruised, when unless used directly the oil has an unpleasant flavor. The olives are crushed in a mill of very simple construction, when the workmen remove the pulp, put it into sacks, and subject it to a very gentle pressure. The first oil extracted, and used for culinary purposes, is of the purest quality, and is called virgin salad oil. The pulp is next thrown into boiling water, from the surface of which the oil is skimmed. Even after this second process a certain quantity is left among the refuse, but being of a very inferior sort it can be used only in making the coarser soaps, plasters, &c. The virgin oil, as soon as it is obtained, is conveyed to a reservoir, where it is kept until required for shipment. The port of Gallipoli, from which so much of the best oil is obtained, owes much of its celebrity to its being built on a rocky island, where fine reservoirs are easily excavated, in which the oil soon clarifies and may remain for years without becoming rancid. In 1843 the province of which Gallipoli is the principal port produced nearly 22,000 tons of oil. In the southern countries of Europe olive oil is extensively used as an article of food, in the arts, and in medicine, and is thought when rubbed into the skin to afford protection to some extent against the plague. The finest sorts are used by watchmakers, as they become viscid more slowly than any other vegetable oil. The best oil is distinguished by its greenish color, and is usually imported from Italy and France in glass bottles, or in flasks covered with a network of grass, called Florence flasks. It has but little smell and a slightly sweetish taste, but by exposure to the air or heat it becomes rancid and disagreeable. Its specific gravity is 0.9153. At 88° F. it congeals in part, but a portion, which is uncombined oleine, remains liquid. The more solid part is a definite compound of oleine and margarine. Olive oil is often adulterated with the cheaper fixed oils, the presence of which is indicated when the

oil is reduced to the freezing temperature, the oils used as adulterants not congealing as does the olive oil. Castile soap is made of olive oil mixed with alkalies. A manufacture of this article is carried on at Marseilles. The imports of olive oil into the United States for the year ending June 30, 1859, amounted to \$585,975, of which \$388,685 worth was from France, and the rest chiefly from Italy.—There is a species of olive tree (*O. fragrans*, Thunberg) much cultivated in China and Japan for its flowers, which are remarkably sweet-scented, and said to be used in giving flavor to tea. The Cape olive (*O. buxifolia*, Miller) is a tall tree, with coriaceous, oblong, dense, and rigid leaves. The devil wood of the United States (*O. Americana*, Linn.) is a beautiful shrub or small tree, 15 to 20 feet high, with oblong or obovate-oblong, smooth, coriaceous, and shining, light green, perennial leaves, narrowing into a petiole and 3 to 6 inches long; small, pale yellow, strongly scented, and fragrant flowers, and round purplish blue fruit, consisting of a drupe as large as a pea, which is bitter and astringent to the taste. It occurs in light rich soils near the coast of southern Virginia and southward, flowering in April and May.

OLIVER, ANDREW, lieutenant-governor of Massachusetts, born in 1707, died in Boston, March 8, 1774. He was graduated at Harvard college in 1724, became a member of the general court, and afterward of the council, and in 1756 was appointed secretary of the province. When the stamp act was passed by the English parliament, he made himself obnoxious by accepting the office of distributor of stamps, and on Aug. 14, 1765, was hanged in effigy from the "liberty tree," emblems of Bute and Grenville being suspended beside the figure. Gov. Hutchinson ordered the sheriff to remove the images, but the citizens said: "We will take them down ourselves in the evening." Accordingly, in the evening of the same day, the mob cut down the effigy, and burned it in front of Oliver's house. Oliver was so much alarmed that he appeared the next day before the people under the "liberty tree," and publicly resigned his office. In 1771 he was appointed lieutenant-governor. He was thought to be much under the influence of Gov. Hutchinson, his brother-in-law, and he pursued the same public course, promoting as much as was in his power the designs of the British ministry, as was proved by his letters, which were obtained by Franklin in England, and sent back to America in 1772. When therefore the general court petitioned the king for the removal of Hutchinson, they included Oliver's name also.—PETER, chief justice of Massachusetts, brother of the preceeding, born in 1712, died in Birmingham, England, in Oct. 1791. He was graduated at Harvard college in 1730, afterward filled several stations in Plymouth co., and in Sept. 1756, was promoted to the chief justiceship of the superior court. In March, 1774, the house of representatives, voting the

judges of the superior court sufficient salaries from the colonial treasury, ordered them to refuse any gifts from the king. Four of them complied, but Oliver refusing, the house impeached him, and suspended him from his functions till the conclusion of his trial. He incurred general odium by his conduct, siding openly with the tories; and when the British troops evacuated Boston, he went with them, and finally removed to England, where his salary, or more likely a pension, was given him by the crown. He was a writer of some talent, and contributed to a tory paper called the "Censor." He was an enthusiastic antiquary, transcribing with his own hand the MS. history of William Hubbard, and carrying away with him when he left America, records and papers which he had collected concerning the early settlement of Plymouth colony.

OLIVES, MOUNT OF, or MOUNT OLIVET (Arab. *Jebel et-Tur*), a mountain of Palestine celebrated in biblical history. It is situated a few hundred yards E. of Jerusalem, separated from it by the valley of Jehoshaphat, through the bottom of which flows the brook Kidron. It is a ridge rather than a single hill, having 3 summits. The centre, a little rounded top on which stands the village of Tur, is 2,786 feet above the sea and 458 above the valley; and being 190 feet higher than the most elevated part of Jerusalem, and only half a mile from the walls, it is before one's eyes from nearly all the streets, and affords the most favorable view of the city. The sides are partly cultivated in terraces, streaked here and there with bare rock, and dotted with the olive trees from which the mountain has its name. It was from this central summit that a very old tradition reports the ascension of Jesus to have taken place; and a church was built here by the empress Helena on the site of one now occupied by the Armenians. The garden of Gethsemane lies on the declivity near the foot of the hill. The central summit is apparently the highest, though according to Maundrell the northern is the highest. Toward the N. the ridge sweeps around to the W. and spreads out into the high level tract of the city. On the S. it sinks down into a lower ridge over against the "well of Nehemiah," now called by the Franks the "Mount of Offence," in allusion to the idolatrous worship established by Solomon "in the hill that is before Jerusalem." From this summit the Dead sea may be seen. On the E. the Mount of Olives overlooks the "wilderness of Judaea," which stretches over a succession of desolate hills for a distance of 10 m., and is then bounded by the valley of the Jordan. The road to Bethany passes over Mt. Olivet. The Saviour used to sit here with his disciples, and retire hither alone to rest and pray. It was here that he delivered some of his parables, and passed the last night before he was seized and delivered up to Pontius Pilate. Many sacred spots are now pointed out to pilgrims on and about the mountain.

OLIVIER, GUILLAUME ANTOINE, a French entomologist, born in Fréjus in 1756, died in Lyons in 1814. He was graduated M.D. at Montpellier, afterward gave his attention exclusively to the natural sciences, and undertook to write an illustrated account of the *coleoptera* for a projected entomological history, and a natural history of insects for the *Encyclopédie méthodique*. These labors were interrupted by the French revolution, and in 1792 Olivier and Bruguière were sent by Roland, then minister of the interior, on a commercial and scientific mission to Persia. On his return from his eastern journey, which lasted 6 years, Olivier published a *Voyage dans l'empire Ottoman, l'Égypte et la Perse* (3 vols. 4to., Paris, 1802-7). The first part of his *Histoire naturelle des coléoptères* appeared in 1789, and the work was brought to a conclusion in 1808, in 6 vols. 4to. with 863 plates. His more bulky *Dictionnaire de l'histoire naturelle des insectes* (9 vols. 4to., 1789-1819) was in such a state of forwardness at his death as to permit his coadjutors Mauduyt, Latreille, and Godard to complete it. He was elected a member of the academy of sciences in 1789.

OLLA PODRIDA (Span., putrid mess), the name of a Spanish national dish, consisting of several kinds of meat cut up into small pieces, and stewed with a variety of vegetables. The dish is a great favorite with the poor, and is kept so long that its odor and flavor become highly offensive, and from this it has derived its name. It also signifies a vase of flowers of various kinds, and is commonly used, like *pot-pourri*, metaphorically to denote a medley.

OLMSTED, DENISON, LL.D., an American savant, born in East Hartford, Conn., June 18, 1791, died in New Haven, Conn., May 13, 1859. His father died when he was only a year old, but he was carefully instructed by his mother. From his 12th to his 16th year he was a member of Gov. Treadwell's family, and a part of the time a clerk in a store of one of the governor's sons. He was graduated at Yale college in 1809, and almost immediately took charge of the union school at New London. In 1815 he was chosen a tutor in Yale college, soon after which he began the study of theology with a view to the ministry. His plans were changed, however, by his appointment in 1817 to the professorship of chemistry, mineralogy, and geology in the university of North Carolina. Here he distinguished himself by proposing and executing the first state geological survey ever attempted in this country. Though made by authority of the state, his services were rendered gratuitously. The report was published in 1824 and 1825. In the latter year he was appointed professor of mathematics and natural philosophy in Yale college; in 1836 the professorship was divided at his request, and he retained the department of natural philosophy. In 1831 he published the first volume of a treatise on natural philosophy which he had prepared for his classes, and which soon be-

came a popular college text book. The 2d volume followed a little more than a year later, and very soon after a "School Philosophy," abridged from the larger book, which has had a very large sale. In 1889 he published a treatise on astronomy for college use, and the next year a "School Astronomy." In 1842 appeared his "Rudiments of Natural Philosophy and Astronomy," intended as a primary book, and not long after his "Letters on Astronomy," prepared at the suggestion of the Massachusetts board of education. At the time of his death he had made considerable progress in a revision of these text books, demanded by the subsequent progress of science. In addition to his professional duties, he devoted much time to the prosecution of other kindred branches of physical science. As early as 1830 he prepared and published an elaborate theory of hail storms, which called forth much discussion, but finally received the general approbation of meteorologists. The extraordinary shower of shooting stars which fell in Nov. 1833, attracted his attention, and he pursued his investigations into their history and phenomena for many years, till he had satisfactorily demonstrated their cosmical origin. In 1835 Prof. Olmsted and Prof. E. Loomis, then a tutor at Yale, were the first American observers of Halley's comet. Prof. Olmsted made a series of observations for several years on the aurora borealis, the results of which are given in the 8th volume of the "Smithsonian Contributions to Knowledge." Possessing a considerable degree of mechanical talent, he used it in promoting and perfecting the inventions of others, and occasionally in the invention of articles which would enhance the comfort or convenience of the community. Very few of these inventions were secured by patent. One was a stove, long known as the Olmsted stove.

OLMSTED, FREDERICK LAW, an American author and landscape gardener, born in Hartford, Conn., Nov. 10, 1822. He studied engineering and the sciences bearing on agriculture during parts of 1845 and 1846, at Yale college, and then engaged himself as a laborer on a farm in central New York, with the view of learning the practical details of farming. Subsequently he managed a farm of his own on Staten island, at the same time writing for periodicals on rural subjects, and enjoying the friendship of Mr. Downing and others, who were then drawing public attention to the arts of landscape gardening and domestic architecture. In 1850 he made a pedestrian journey through Great Britain and portions of the continent, with the purpose of observing closely the agriculture and the ornamental grounds of those countries. Some of the results of this journey were embodied in a little work called "Walks and Talks of an American Farmer in England" (New York, 1852). In 1852-'3 he made extended journeys in the southern and south-western states, mostly on horseback, with the view of examining the agricultural resources

of those states, and of studying the effects of slavery upon agriculture. His observations and conclusions have been published in three different works: "A Journey in the Seaboard Slave States, with Remarks on their Economy" (New York, 1856); "A Journey through Texas, or a Saddle Trip on the South-Western Frontier, with a Statistical Appendix" (1857); and "A Journey in the Back Country" (1860). In 1855 he made another tour through France, Italy, and Germany, during which he paid especial attention to parks and rural arts. The following year a commission was formed under an act of the legislature for the construction of a large central park in the city of New York, and he was appointed by them as superintendent. In 1857 premiums were offered by the commission for the best plans for the ground, and of 84 plans sent in with sealed names, the highest prize was awarded to that prepared by Mr. Olmsted in conjunction with Mr. C. Vaux, which was adopted for the laying out of the park. Mr. Olmsted was subsequently appointed architect and chief engineer, having thus the duty of organizing the laboring force on the park, as well as of laying out its grounds and watching all the details of its construction. Since that time, from 2,000 to 4,000 men have been generally at work on the grounds, beside those engaged by contractors; and, with but one unimportant exception, there has never been any strike for wages or any disorder whatever among them. Mr. Olmsted made another short European journey in 1859, and is now (1861) engaged on the central park, as well as in laying out the upper part of New York island, and other similar enterprises.

OLMÜTZ (Slav. *Holomaue*), a town of Austria, formerly the capital of Moravia, now of a circle of its name in that province, and one of the principal fortresses of the empire, situated on an island of the March or Morawa; pop., excluding the garrison, 15,000. It is well built, and contains several suburbs, fine squares and promenades, and numerous institutions of learning or benevolence. It is the seat of an archbishop and of various offices of provincial administration. There are some woollen and other manufactures, and an active trade in cattle, which is promoted by large annual fairs visited by traders from Silesia, Galicia, Hungary, Bohemia, and other parts of the Austrian empire. The railway which connects the great Vienna and Breslau and Vienna and Prague lines passes by the town. Among the most remarkable buildings are the cathedral, the church of St. Maurice, containing a celebrated organ, St. Michael's, various convents, the archbishop's residence, the town house with a famous clock, a theatre, and the university. The latter institution, which contains a library with 50,000 volumes, was founded in 1581, removed to Brünn, the new capital of Moravia, during the reign of Joseph II., and restored in 1827.—Olmütz is one of the oldest towns of Austria, its origin being traced to the times of

the Roman empire. During the middle ages it received numerous privileges from the margraves of Moravia, the kings of Bohemia, and the emperors. It withstood an assault of the Mongols in 1241, and a siege of Béla IV. of Hungary in 1258; joined the revolt against Ferdinand II. at the beginning of the 30 years' war in 1619; was, during the same war, taken by the Swedes under Torstenson in 1642, and retaken by the imperialists; was taken by the Prussians in the first war of the Austrian succession, but besieged by them in vain during the 7 years' war. Among the numerous prisoners of state who at various periods have been confined in the dungeons of Olmütz, was Gen. Lafayette. After the revolution of Vienna in Oct. 1848, the Austrian court having fled to Olmütz, the emperor Ferdinand resigned there his crown, and his nephew, Francis Joseph, was proclaimed his successor (Dec. 2). The difficulties between Prussia and Austria arising from the revolutionary movements in Hesse, which in the autumn of 1850 threatened the peace of Europe, were settled by a conference of ministers held at Olmütz in the last days of November in that year. The emperors Nicholas and Francis Joseph met there shortly before the outbreak of the Crimean war in 1853.

OLONETZ, a northern government of European Russia, bounded N. and E. by the government of Archangel, S. by Vologda, Novgorod, and St. Petersburg, and W. by Lake Ladoga and Finland; area about 51,000 sq. m.; pop. in 1856, 285,945, mostly Russians, Finns, and Lapps. The surface is in great part covered by vast forests, marshes, and lakes. Of the latter, beside Lake Ladoga on the border, the largest are Lakes Onega and Vigo. The principal rivers are the Onega, which flows through Archangel into Onega bay, an outlet of the White sea; the Svir, which connects Lakes Onega and Ladoga; and the Vodla, which flows from the lake of the same name into Lake Onega. There are some mountains in the N. W. The winters are very long, and the short summers excessively hot. Agriculture is much neglected; hemp and flax are among the principal articles raised. Fishing and hunting are leading occupations of the inhabitants, foxes, reindeer, badgers, water fowl, and fish being abundant. Pasturage is scarce, and grazing neglected. Some iron, copper, silver, and marble are mined. The principal towns are Petrozavodsk, the capital, on the W. shore of Lake Onega, pop. about 7,000; Olonetz, the former capital, a small town near the E. shore of Lake Ladoga; Vitagra, on a river of the same name; and Kargopol, on the Onega river.

OLSHAUSEN, HERMANN, a German Protestant theologian, born in Oldesloe in Holstein, Aug. 21, 1796, died in Erlangen, Sept. 4, 1889. He studied theology at Kiel and Berlin from 1814 to 1818, when he became private tutor in the latter place, in 1821 extraordinary professor in Königsberg, and in 1827 ordinary professor of theology. In 1834 he went to Erlangen as

ordinary professor, and remained there until his death. He devoted his attention chiefly to the exegesis of the New Testament. His *Biblicher Commentar über sämtliche Schriften des Neuen Testaments* (1830), the most celebrated of his works, was translated into English for Clark's "Foreign and Theological Library;" and an American reprint, revised after the 4th German edition by Professor A. O. Kendrick of Rochester university, was published in 1857 ("Biblical Commentary on the New Testament," 5 vols. 8vo., New York).—JUSTUS, a German oriental scholar, brother of the preceding, born in Hohenfelde, Holstein, May 9, 1800. After receiving his education at the universities of Kiel and Berlin, he went to Paris at the expense of the Danish government, and studied the oriental tongues under Sylvestre de Sacy. In 1848 he was appointed by the provisional government curator of the university and director of the medical faculty, and was elected by the city of Kiel to the assembly of the duchies, of which body he remained vice-president till the end of 1849. Here he signalized himself by his devotion to the cause of Germany; and after the submission of the duchies in 1852, he was deprived by Denmark of his position as curator and also as teacher. By the Prussian government he was made in 1853 librarian in chief and professor of oriental languages at the university of Königsberg. He has published various important works on oriental and scriptural subjects.

OLYMPIA, a plain of Elis in Greece, situated on the right bank of the Alpheus, 800 stadia from the town of Pisa. It was the seat of the Olympic games, and was also famous for its sacred grove, where stood the great temple of Jupiter Olympius, founded by the Eleians in 512 B. C., and containing the colossal gold and ivory statue of the god, the masterpiece of Phidias I. The grove (which was surrounded by a wall) and its immediate neighborhood contained numerous other temples and public buildings, collectively, like the plain, called Olympia.

OLYMPIAD. See CHRONOLOGY, vol. v. p. 208.

OLYMPIAS, daughter of Neoptolemus I., king of Epirus, wife of Philip of Macedon, and mother of Alexander the Great. Her imperious and jealous nature, and the infidelity of Philip, caused much strife between them; and on the marriage of Philip with Cleopatra, the niece of Attalus, in 337 B. C., she fled to the court of her brother Alexander, king of Epirus, whom she incited to make war upon Macedon. On the death of Philip, whose assassination she was said to have approved, if not caused, she returned to Macedonia, and put to death her rival Cleopatra, and her infant daughter. She was constantly at feud with Antipater, the regent during the conquering expeditions of Alexander; and when by the death of the latter in 323 he was placed in absolute control of affairs, Olympias withdrew to Epirus, and tried various schemes for his

overthrow. On the death of Antipater in 319, the new regent Polysperchon sent for her to return to Macedonia, and take charge of the young prince Alexander, the son of Roxana. She declined, and determined to remain in Epirus until the war should be terminated. But in 317 she took the field in person, together with Polysperchon, against Eurydice, whom she defeated and put to death. She also put to death Nicanor, brother of Cassander, and 100 of his followers. But she was at last defeated and slain by Cassander at Pydna in the spring of 316.

OLYMPIC GAMES, the most ancient and famous of the 4 great national festivals of the Greeks, celebrated once in every 4 years at Olympia, a plain in the territory of Elis, on the banks of the river Alpheus, and in the immediate vicinity of the temple of Olympian Jove. Their origin is lost in the mythical ages, but, like that of the other Hellenic games, was probably connected with the rites paid to some deity; and from the close association which in the heroic epoch prevailed between the feelings of common worship and the sympathy in common amusement, they gradually expanded into a festival partly religious and partly secular in its character. After having been interrupted or discontinued for a considerable period, the Olympic games were reestablished about 844 B. C. (so far as any approximation to accuracy in dates can be made), by Iphitus, king of Elis, and Lycurgus the Spartan lawgiver, who, according to Pausanias, were commanded by the Delphic oracle to revive the festival as a remedy for intestine commotions and for pestilence with which Greece was then afflicted. For upward of a century after this, however, the games continued a local festival, frequented chiefly by the neighboring Peloponnesian races; but as they grew in importance, spectators came from the more distant states and from the Greek colonies of Asia, Africa, and Europe, until, in the zenith of its fame, the festival presented an assemblage of the representatives of the Hellenic tribes such as no other occasion could bring together. Except in two or three instances, the management of the games was in the hands of the Eleans, who appointed certain of their number called Hellanodiceæ (Ἑλλανοδικαί) to preside as judges. As the time approached for the celebration of the games, a sacred truce was proclaimed, and during the month in which they took place the Elean territory was considered so inviolable that any armed invasion was esteemed an act of sacrilege. At the same time hostilities were suspended throughout Greece. At first the festival was confined to a single day, and consisted of the *δρομος* or simple match of runners in the stadium, which was about 600 English feet in length. In 776 B. C. the Eleans inscribed the name of their countryman Coræbus as victor in the competition of runners, and for nearly 1,000 years afterward we have regular lists of the victors in the foot

races, to which in later times the names of those successful in other games were added. This date was subsequently employed by the Greeks as a chronological era, and the Olympiads, as the periods between two celebrations were called, commencing with the year 776 B. C., from which the first is reckoned, have supplied historical computers with one of the oldest backward records of continuous time. In this respect the games possess an importance beyond their significance in illustrating the social life of the ancient Greeks. In the course of time the festival was varied by additional contests, and subsequent to the 77th Olympiad (472 B. C.) its duration was extended from one to 5 days. In the 14th Olympiad (724) the *διαιλος* or double stadium for runners was introduced, and in the 15th the *δολιχος* or long course, in which the stadium was traversed several times. In the 18th Olympiad (708) several kinds of wrestling matches were added, and also the complicated *πενταθλον*, which included leaping, running, throwing the quoit, throwing the javelin, and wrestling. To gain a victory in the latter contest the competitor was obliged to conquer in each of its 5 parts. In the 23d Olympiad (688) boxing was introduced, and in the 38d (648) the *παγκρατιον*, which consisted of boxing and wrestling combined, the cestus, or leather thong about the hands and arms, being allowed in the first contest but not in the second. In both games the combatants fought naked. The race with four-horse chariots, for which a special course called the *ιπποδρομος*, about 2,400 feet in circuit, was set apart, was introduced in the 25th Olympiad (680), and became one of the most popular and celebrated of all the matches, testing at once the skill of the charioteer and the endurance of the horses, who were obliged to make the circuit 12 times, a distance of over 5 miles. In addition to these there were foot races in which the runners wore heavy armor, several kinds of races on horseback, races between chariots drawn by two horses or by mules, wrestling and running matches between boys, and other athletic contests, some of which were speedily abolished. Unlike the gladiatorial shows of the Romans or the tournaments of the middle ages, the Olympic games included no combats with any kind of weapons—a feature indeed incidental to all the great national festivals of the Greeks. The games were open to persons of all ranks and occupations, the only conditions being that they should prove a pure Hellenic descent and a character free from infamy and immorality. But after the conquest of Greece by the Romans, the latter were allowed to become competitors. In the chariot races the rich were necessarily the sole competitors, and such persons were allowed to employ others as drivers or riders; but in the gymnastic contests rich and poor contended on equal terms, and the victory was as much prized by the former as by the latter. In all cases the combatants were obliged to

undergo a preparatory training, and to take a solemn oath to eschew fraud or unfairness in reference to the contests. Any attempt to bribe a competitor to give the victory to his antagonist was punished by a heavy fine. In the earlier celebrations, as in the Homeric games, the prizes seem to have had some intrinsic value; but after the 7th Olympiad, in which Daicles the Messenian received for his victory in the stadium a wreath from the sacred olive tree near Olympia, this simple reward, with the honor of being proclaimed victor, which was an object of ambition with the noblest and wealthiest of the Greeks, was considered a sufficient recompense. The victor thenceforth became a marked man in his state, upon which as well as upon his family he was considered to have conferred everlasting glory; ovations and many substantial honors awaited him on his return home; his praises were sung by the most eminent poets; and his statue was often erected at the expense of his fellow citizens in the Altis, or sacred grove of Jupiter at Olympia. No women were allowed to be present at the celebration of the games under penalty of death, a single exception being made in the case of the priestess of Demeter Chamyne, to whom a seat was assigned opposite to the judges; but women were allowed to enter chariots for the races, and frequently did so. The concourse of men, however, particularly after the expulsion of the Persians from Greece, which by strengthening the Pan-Hellenic feeling, had lent additional dignity to the festival, was very great, and included representatives of all the principal branches of commerce and the arts. Many literary works were here first publicly recited, although such recitations were not contests and formed no part of the festival proper; and painters and sculptors found abundant means to dispose of their productions. Many persons were also present as *deuatoi* or deputies from the various states and colonies, and by the number of their offerings and the splendor of their retinues greatly added to the reputation of the festival. The Olympic games preserved their crowds of visitors and their celebrity for many centuries after the extinction of Greek freedom, but at length were finally abolished, after more than 1,100 years of continuance, by a decree of the Christian emperor Theodosius, A. D. 394. In 1858 M. Zappas, a wealthy Peloponnesian, contributed a fund for their reestablishment, under the auspices of the queen of Greece.

OLYMPUS, MOUNT, a lofty group of mountains in Greece, lying partly in Macedonia and partly in Thessaly, of which latter country it forms the N. E. boundary. It terminates on the S. at the mouth of the river Peneus, on the shore of the Thermaic gulf, and is separated by the vale of Tempe from the neighboring heights of Ossa, both mountains forming the E. extremity of the Cambunian range. Its highest peak has an elevation of 9,754 feet. The slopes are in many places richly clothed

with forests, but toward the summit, which is broad and covered with snow for the greater part of the year, the mountain is broken into vast, rugged precipices, indented at intervals with deep ravines. Its modern name is Elymbo (Ελύμπος). In Greek mythology Mount Olympus was the residence of Jupiter and the chief celestial deities, and the clouds which veiled its summit were supposed to conceal the entrance to the vault of heaven. In Mysia, Galatia, Lycia, Cyprus, and elsewhere, were mountains called by this name, which is also borne by an eminence bordering on the plain of Olympia in Elis, where were celebrated the Olympic games.

OLYNTHUS (now *Aio Mamas*), an ancient town of Chalcidice in Macedonia, situated at the head of the Toronaic gulf. It was early inhabited by Greeks, was taken by the Persians under Artabazus, one of the generals of Xerxes, was next subject to Athens, and regained its independence when the Spartan general Brasidas extinguished the Athenian power in Chalcidice. From its excellent maritime position, it grew in wealth and importance, until, becoming too powerful, the Spartans captured it in 379 B. C. In 852 the Olynthians formed an alliance with the Athenians, which provoked the hostility of Philip of Macedon, and in 847 the city was betrayed to him, the citizens were sold, and every building was demolished.

OMAR I. (ABU HAFSSAH IBN-AL-KHATTAB), the 2d caliph of the oriental (Arabian) dynasty, and 8d cousin of Abdallah, the father of Mohammed, born in 581, assassinated in 644. Originally a bitter enemy of the prophet, he set out for Medina with the intention of murdering him; but on his way, chancing to read the 20th chapter of the Koran, he was converted. Henceforth he became so zealous a supporter of the Moslem faith, that Mohammed said that "if God should wish to send a second messenger into the world, his choice would undoubtedly fall on Omar." So disinterested was he, that when the prophet died in 632, he resigned his claim to the supreme rule in behalf of Abubekr; and when the latter on his deathbed appointed him his successor (634), he unwillingly accepted. "I have no occasion for the place," said he. "But the place has occasion for you," replied the dying caliph. During his reign the Moslem arms were victorious everywhere. One army prosecuted the conquest of Syria, took Damascus in 635, defeated the Greeks in the bloody battle of Termuk, and in 637 compelled Jerusalem to capitulate. Another army under Amru invaded Egypt, reduced Alexandria (at which time the library founded by Ptolemy Philadelphus is said to have been destroyed), and overran Africa as far as the deserts of Tripoli and Barca. In Persia and Armenia the Moslems were also successful; and a Mohammedan historian sums up the conquests of Omar by saying: "He took from the infidels 36,000 cities or castles, destroyed 4,000 temples and churches,

and founded or endowed 1,400 mosques." In Nov. 644, while performing his morning devotions in the mosque at Medina, he was stabbed three times by a Persian slave named Firiez, who had applied to him in vain to be relieved of half the tribute he was compelled to pay his master. He lingered 5 days, refusing to name his son as successor, saying: "It is enough that out of my family one has been forced to bear this burden, and account afterward to God for the command and government of the faithful." Omar's only food was barley bread and dates; his only drink, water; and his garment an old coat torn in 12 places. He regularly distributed the contents of his treasury among his soldiers and followers, and supported himself by the work of his own hands, manufacturing and selling leather belts. A large portion of his time was devoted to prayer, and during his life he made several pilgrimages to Mecca. So zealous was he for the exact administration of justice, that, according to the historian Wakedi, the staff of Omar was more dreaded than the sword of his successors. He was the first to assume the title of Emir-al-Mumenin, or commander of the faithful, and some of the most useful Mohammedan institutions date from his reign. In his time the era of the Hegira was established, armies were first kept upon pay, and a sort of police force instituted. Omar has always been an object of reverence among the Moslems of the Soonnee or orthodox sect, and it has been thought that he did more to advance the cause of Mohammed than the prophet himself.

OMAR II. (ABU HARRAS), 8th caliph of the Ommyiades, succeeded Solyman in Sept. 717, died in Jan. 720. He was a descendant of Omar I., and endeavored to imitate the example of that monarch. It was the chief effort of his reign to reconcile the houses of Omar and Ali, and for that purpose he revoked the maledictions against the partisans of the latter, which had been read in all the mosques since the time of Moawiyah, and restored them the lands given to Ali by the prophet. But several members of the ruling family, alarmed at this conduct, administered to him a slow poison, of which he died after having reigned 2 years and 5 months. Although exceedingly economical as regarded himself, his liberality had been so excessive, that there was not sufficient money left in the treasury to pay his funeral expenses.

O'MEARA, BARRY EDWARDS, an Irish surgeon, born in 1770, died in London, June 8, 1836. He was educated at Trinity college and at the royal college of surgeons, Dublin, and served several years in Sicily, Egypt, and Calabria, as assistant surgeon to the 62d regiment. He was afterward surgeon in the navy, and was appointed to the Bellerophon in Aug. 1815, when Napoleon came on board that ship as a prisoner. At the request of Napoleon, who was attracted by his knowledge of Italian and his professional skill, O'Meara accompanied the ex-emperor to St. Helena, in

the capacity of medical attendant, and acquitted himself to the satisfaction of Sir George Cockburn and his successor Sir Pulteney Malcolm. But a rupture taking place between him and Sir Hudson Lowe in regard to the treatment of Napoleon, he returned to England, where he was well received. Having accused Sir Hudson Lowe before the admiralty of cruel and arbitrary conduct, his name was erased from the list of naval surgeons. He afterward acted with the extreme liberals, and was a partisan of Daniel O'Connell. He published the *Manuscrit de l'île d'Elbe*, by Napoleon; "Letters from the Cape of Good Hope;" "Letters from St. Helena;" "Letters from Count Las Cases," with a preliminary discourse; "Exposition of the Treatment of Napoleon Bonaparte;" a translation of the "Memoirs of Napoleon" by himself, and "A Voice from St. Helena, or Napoleon in Exile."

OMEGA. See ALPHA.

OMEN (Lat.), a sign believed to prognosticate a future event, between which and the event foretold there appears no relation of cause and effect, but which is usually received as an intimation from a superior power. Omens have been common among most nations, and are often remembered and mentioned after they have ceased to be credited. Though generally classed among superstitions, they may sometimes be founded on some hidden relation in things, some natural law of sequence the ground of which is unknown. They have been chiefly in vogue in the ruder ages and communities, though under the name of auguries they retained their influence during the whole period of pagan antiquity, and though eminent warriors and other popular leaders in moments of extreme doubt and peril have given notable examples of faith in them. Suetonius mentions that Cæsar, on landing at Hadrumetum in Africa, happened to fall upon his face, which would have been an unlucky omen had he not transformed it into a symbolical act by exclaiming as he touched the earth: *Teneo te, Africa* (I take possession of thee, O Africa). Valerius Maximus relates that Pompey on arriving at Paphos after the battle of Pharsalia lost the remnant of his hopes when he discovered the name of the palace concerning which he inquired (*Kakopavdeia*, evil palace). It is stated by Winheim that Melancthon went forth from the assembly at Torgau in anxious doubt concerning the future of the reformation, but found in the antechamber three women, one of whom was holding a new-born child, another was supporting and instructing a boy, and the third was giving food to a full-grown man; and that he immediately returned into the hall, and so encouraged the assembly by reporting the favorable symbolical omen, that bolder and more decisive resolutions were at once carried. Sir Thomas Browne mentions the old English and French superstition, which is also found in the fathers of the church, and to which Weston assigns an oriental origin, that

a child's caul was not only a happy omen to the child itself, but would also guard from danger whoever might obtain it by purchase. During the present century such cauls have been advertised for sale at high prices in the London "Times." Sneezing was deemed ominous in the time of Homer, and Eustathius states that it was lucky or unlucky according as it was directed to the right or the left. Aristotle discusses the problem why sneezing from noon to midnight is good, and from midnight to noon bad. At noon it was propitious. Among the ancient Persians sneezing was esteemed fortunate, a sign of contest between the fiery soul and the earthly body, and of the victory of the former. When the emperor of Monomotapa sneezes, says Codignas, it is proclaimed through the whole land as a signal for general joy. In every age dreams have by some been regarded as divine revelations. The following are examples of omens from them: to dream yourself or friend to be buried foretells a serious fit of illness; to dream of death denotes happiness and long life; to dream of flying signifies presumption and vain ambition; to dream of gold promises success, and of silver misfortune; to dream of a hen and chickens proves you will be married to a widow or widower with many children; to dream of serpents is a sign of impending perils; to dream of a fall predicts loss of character. It is an old English rustic custom for girls to fast on St. Agnes' day, and to put a Bible under their pillows with a sixpence clapped in the book of Ruth, in order to dream of the men destined to be their husbands. In parts of Scotland and in some other localities, it betokens the utmost good fortune during the month to see the moon for the first time after her change on the right hand or directly in front; to turn the head back to see it, especially over the left shoulder, foreshadows the worst fortune. It is also held unlucky to look at the new moon for the first time through a window. The belief in the fatal influence of the waning moon on all projects begun under it was, according to Dr. Jamieson, general in Scotland. Bishop Hall mentions the falling of salt toward persons at table and the spilling of wine on their clothes as evil omens, which were also believed by the Germans to forebode calamity and feuds. Putting the shoes on awry or on the wrong feet has often been thought the forerunner of some unlucky accident. Augustus put his sandals on wrongly on the very morning he narrowly escaped death by a mutiny. Breaking a looking glass betokens the death of the best friend of the person to whom it belonged. Constant relates that during one of his Italian campaigns Napoleon broke a mirror over Josephine's portrait, and that so strong was the impression made by the event on his mind that he immediately despatched a courier to assure himself of her safety. Sir Thomas Browne discusses the proverb that our cheeks burn or ears tingle when others are talking of us. The left cheek or ear

indicated that they were talking ill; the right, well. The itching of the nose implied that a stranger was coming. Burton in his "Anatomy of Melancholy" states that "to bleed three drops at the nose is an ill omen." The spots on the finger nails were all ominous; the itching of the palm of the right hand promised a receipt of money; the doubling of the thumb within the hand was believed to have efficacy in avoiding approaching danger, and therefore the thumbs of dead persons were so folded. The way in which fires, candles, or lamps burned suggested divers omens. The superstition still prevails in many places that the howling of a dog by night presages a death in the neighborhood. Duncan Campbell expresses his faith in this omen, and adds: "Odd and unaccountable as it may seem, those animals scent death, even before it seizes a person." The screeching of the owl and the croaking of the raven have both in ancient and modern times been regarded as omens of some dire calamity. Divers presages concerning the weather have been derived from the habits of birds, bees, wasps, gnats, &c. Pennant states that many of the great families of Scotland received monitions of future events, especially of death, by spectres, wraiths, and shrieks. Fishermen and sailors discover omens in echoes, flashes, shadows, and other visible appearances. To throw a cat overboard, or lose a bucket, is believed to be unlucky. Whistling is supposed to stir up the wind. Stumbling has been the subject of numerous superstitions. Cains Gracchus stumbled at his threshold on the morning of his death. To stumble on going out, says Bishop Hall, was mischievous; to stumble up stairs, says Grose, was lucky.

OMER, a measure. See HOMER.

OMER PASHA (MICHEL LATTAS), a Turkish general of Croatian origin, born in Plaski, a village of Croatia, in 1806. His father held a position of importance in the Austrian civil service. The son was educated at the military school in his native place, and at Thurm near Carlstadt, distinguishing himself by his knowledge of mathematics and the beauty of his handwriting, to which latter circumstance he owes much of his success. He was made a cadet in the frontier regiment of Ogulin, and subsequently appointed assistant to a surveyor of roads and bridges; but becoming disgusted with keeping accounts and mending highways, he left the Austrian service, resided for some time at Zara in Dalmatia, and then passed over into Bosnia. Here he was first employed as a book-keeper by a Turkish merchant, and afterward became tutor of the children of Hussein Pasha, the exterminator of the Janizaries, who in 1834 sent him to Constantinople. He had previously adopted the Mohammedan religion and assumed the name of Omer. Here he became professor of penmanship in the new military school, was appointed an officer in the army, and became writing master to Abdul Medjid, the present sultan. He took part in the reorganization of the Turkish forces, and spent two

years in Bulgaria and in the Danubian principalities in topographical studies. In 1839 he was made colonel, served in the campaign against Ibrahim Pasha with distinction, and on his return was promoted to the rank of brigadier-general. He also bore a principal part in the pacification of Albania, and in quelling the revolt of Koordistan. In 1848 he was appointed commander of the Turkish troops in Moldo-Wallachia, and when in 1849-'50 the Mohammedan inhabitants of Bosnia, indignant at the reforms of the sultan, determined not to receive the *Tansimat*, Omer hastened into that country, and by the rapidity of his operations completely crushed out the insurrection. In the following year he pacified the Herzegovina. In 1852 he was sent against the Montenegrins, and was gradually reducing them when he was recalled in consequence of Austrian diplomatic intervention. In June of the following year the Russian army invaded the Danubian principalities, threatening the passage of the Balkan and the integrity of the Turkish empire. Omer was appointed generalissimo, and immediately began active operations on the line of the Danube, although refusing to fight a pitched battle. Early in November the Russians attacked his troops at Oltenitza, but, after a prolonged engagement, were driven back with great loss. He continued the war in 1854, the vicinity of Kalafat, opposite Widin, being its principal seat; and about the middle of May the Turks were besieged in Silistria by an army of 60,000 men. The siege lasted 40 days, and was finally given up with a loss to the enemy of 10,000. The Russians hereupon repassed the Pruth, and Omer entered Bucharest in August. Early in 1855, acting in conjunction with the French and English commanders, he carried over 35,000 men of his Danubian army to Eupatoria, and began the fortification of that place, where he was attacked on Feb. 17 by a Russian force estimated at 40,000. Although ill provided against an assault, he repulsed the enemy with great loss. Subsequently Omer joined with his forces the allied army encamped near Sebastopol, but took no prominent part in the siege of that place. In the spring he marched his troops into Asia, with the design of relieving Kars and opposing the Russian power in that quarter. Kars was taken, however, before he had gone further than Kutais, and in consequence he retreated to Redout Kale. He was afterward appointed governor-general of Bagdad, in which capacity he delivered that province from the invasion of Arab and Koord tribes. He was accused, however, of fraudulent practices in his administration, and of having passed sentences of death upon several persons without the sanction of the sultan. Riza Pasha, who had been instrumental in the overthrow of Ali Pasha's administration, was also the principal enemy of Omer Pasha; and it was believed to have been chiefly at his instigation that he was found guilty of the charges alleged against

him and banished to Kaarpoot in 1859. About May 1, 1860, he was recalled from exile.—Omer Pasha is European in his habits and conversation, and speaks several foreign languages. With the soldiers he is popular on account of his affability. Decorations have been conferred upon him by the English, French, and Russian governments. In 1850 he married a sister of the Transylvanian general Simunich, who had been a governess in a family of Bucharest. The lady subsequently left him, and arrived in New York in 1860, endeavoring to support herself as a music teacher.

OMMYIADES, the second dynastic line of oriental caliphs, begun with the reign of Moawiyah, the son of Abu Sofian, in the year 41 of the Hegira (A. D. 661), and continued until A. H. 132 (A. D. 750). They derived their name from Ommyyah, an ancestor of Moawiyah. Moawiyah had during the lifetime of Ali, the 4th caliph of the Arabian dynasty, succeeded in making himself master of Syria and Egypt, and after the assassination of Ali gained possession of the whole empire, through the abdication of his successor Hassan. Hitherto the office of caliph had been elective; but it now became hereditary in the family of this monarch, and so continued until the defeat and death of Merwan II., the 14th sovereign of the line (750). During the sway of this dynasty, Kharezm, Turkistan, Spain, and Georgia were conquered, and ineffectual efforts were also made to reduce Constantinople. But the progress of the Moslem arms was in a great measure retarded by the constant civil dissensions which prevailed, and in Europe their conquests were effectually stayed by the defeat they received from Charles Martel on the plains of Poitiers (732). After the contest between Merwan II. and Abul Abbas, the head of the Abbassides, had ended in the defeat of the former, Abdallah, an uncle of Abul Abbas, called a meeting of the Ommyiades, and treacherously massacred them all but two. One of these fled to a corner of Arabia, where his descendants ruled as late as the 16th century; and the other escaped to Mauritania, whence he was called to Spain, and, after defeating the generals of the caliph in two pitched battles, founded the independent caliphate of Cordova as Abderrahman I.

OMNIBUS. See COACH.

OMOA, a port of Honduras, Central America, situated on the bay of Honduras, in lat. 15° 47' N., long. 88° 8' W.; pop. 2,000. The harbor is small but safe, and defended by a large fort built by the Spaniards, called El Castillo de San Fernando. The town is about a quarter of a mile from the shore, on a low, level reach of ground, dominated by the mountains of Omoa. It derives its principal importance from the commerce of the departments of Santa Barbara, Comayagua, and Gracias, which passes through it. Its principal exports are bullion, hides, tobacco, sarsaparilla, and mahogany. Formerly Omoa was the port of entry for Guatemala. Its business is chiefly in the

hands of foreign residents, English, Dutch, Spanish, and American. The climate is unhealthy.

OMPHALE, daughter of the Lydian king Jardanus, and wife of Imolus, after whose death she assumed the administration of the government. Mercury sold Hercules to her for a slave, by whom she had several children. Hercules, to please her, assumed female garments and spun among the female slaves, while she wore the lion's skin and wielded the club.

OMRI, king of Israel. See **HEBREWS**, vol. ix. p. 88.

ON. See **HELIOPOLIS**.

ONOKEN, JOHANN GERHARD, a German clergyman and missionary, born at Varel, Oldenburg, about 1800. In early life he was a domestic servant. Some time after reaching manhood he visited England, where he married, and subsequently returning to Germany opened a book shop at Hamburg, joined the English Independent church, and became the agent of the Lower Saxony tract society and the Edinburgh Bible society. In April, 1884, while the Rev. Dr. Sears (now president of Brown university) was in Germany, Mr. Oncken and 6 others requested him to baptize and organize them as a Baptist church, of which Mr. Oncken was subsequently ordained pastor. In 1885 the American Baptist general convention appointed Mr. Oncken their missionary. He visited almost every portion of Germany and Denmark, preaching, distributing tracts and Bibles, and organizing churches. In Hamburg he was several times imprisoned for preaching and baptizing; but after the benevolence of his family and congregation to the sufferers by the great fire of 1842, the Hamburg senate passed decrees commending their noble conduct, and granting them the privilege of unrestricted worship. From that time Mr. Oncken has been actively engaged in the promotion of his missionary work, publishing editions of the Scriptures for gratuitous distribution, writing and publishing religious tracts and books, visiting the numerous churches he has established in Denmark, Switzerland, Prussia, the smaller German states, and Austria, and editing with the assistance of his daughter a religious journal in English, and another in German. He visited the United States in 1852 to obtain means for the erection of chapels. The report of the American missionary union for 1860 gives the following results of his 25 years' labor in the missionary work. The churches founded have been constituted either directly by him, or by those converted under his ministry, and all the pastors now in the field, as well as all who have labored there during 25 years, were directly or indirectly brought into the ministry through his efforts. There were in 1859 in the German mission 65 churches and 756 preaching stations and out stations, 7,908 members of the churches, and 120 ministers and Bible readers; 1,168 members had been added

to these churches the previous year. There are also 65 Sunday schools, with 1,547 children in attendance, and during the year 14,566 Bibles and Testaments and 458,000 tracts were distributed.

O'NEALL, JOHN BELTON, LL.D., chief justice of South Carolina, born on Bush river, S. C., April 10, 1798. He was graduated at the South Carolina college in 1818, and after teaching in an academy in Newberry, began in 1818 the study of law. He was for a short time called into active military service during the war with Great Britain. Admitted to the bar in 1814, he soon gained a large practice. In 1816, '22, '24, and '26 he was a member of the state legislature, and was speaker of the house during the last two terms. In 1828 he was elected one of the associate judges of the state, and in 1830 became judge of the court of appeals. A decision made in this court, while the nullification doctrine was most vehemently urged in South Carolina, giving offence to the dominant party, it was abolished. In 1847 he became president of the Greenville and Columbia railroad, an office of great difficulty and responsibility, which he held till 1853. In 1850 he was made president of the court of law appeals and of the court of errors, and was subsequently raised by the legislature to be chief justice of the state. As early as 1832 he states that he abandoned the use of spirituous liquors and tobacco "in order to save a friend." In 1841 he became president of the state temperance society, and in 1852 was installed as the head of the sons of temperance of North America. He has furnished many contributions to southern periodicals, among which are reminiscences of the revolution for the "Southern Literary Register." Several of his public addresses have been printed. He has published a "Digest of the Negro Law of South Carolina" (1848); "Annals of Newberry" (1858); and "Biographical Sketches of the Bench and Bar of South Carolina" (3 vols., Charleston, 1859), forming a complete history of the judiciary of the state.

ONEGA, a lake of European Russia, in the government of Olonetz, between lat. 61° and 62° 50' N. and long. 38° 40' and 36° E., extreme length 160 m., greatest breadth 50 m.; area, 4,000 sq. m. Its S. end lies about 120 m. E. of the middle of Lake Ladoga, next to which it is the largest body of fresh water in Europe. The N. part is very irregular in shape, several long peninsulas separating the waters into various prong-like projections. The surface is dotted with islands, the shores are generally rocky, and the water is clear and abounds in fish. Navigation is impeded by shoals and sand banks. At its S. W. extremity it is connected with Lake Ladoga by the navigable river Svir; and the Murinskoi canal unites its affluent the Vitegra with the Kayla, a tributary of Lake Bielo, the outlet of which flows into the Volga. The principal other streams falling into Lake Onega are the Migra, Shuia,

and Vodla.—Onega is also the name of a bay at the S. extremity of the White sea, of a river flowing into the bay, and of a town (pop. 2,000) at the mouth of the river.

ONEIDA, a central co. of N. Y., drained by the Mohawk and Black rivers and their tributaries; area, 1,127 sq. m.; pop. in 1885, 107,749. Through the centre of the county a broad valley extends from E. to W., and toward the N. and S. the surface is broken and hilly. The soil is generally rich and very fertile. Oneida lake lies on the W. border. The productions in 1855 were 782,294 bushels of Indian corn, 975,800 of oats, 624,648 of potatoes, 62,322 of wheat, 54,767 of buckwheat, 24,121 of rye, 124,938 tons of hay, 137,327 lbs. of wool, 616,054 of hops, 3,912,176 of butter, and 3,311,114 of cheese. There were 238 saw mills, 42 grist mills, 12 cotton factories, 18 woollen factories, 21 furnaces, 88 tanneries, 19 newspaper offices, 201 churches, and 38,615 pupils attending public schools. The county is traversed by the Erie and Chenango canals, and partly by the Black river and the Oneida lake canals; and the New York central railroad, which intersects the county, connects at Utica with the Black river railroad, and at Rome with the Watertown railroad. Capitals, Rome and Utica.

ONEIDA, a lake in the central part of N. Y., lying between Oswego, Oneida, Madison, and Onondaga counties, at an elevation of 369 feet above tide water, 30 m. long and 6 to 7 m. wide. It forms a link in the chain of internal navigable waters of the state, and its outlet, Oneida river, after a course of 16 m., falls into the Oswego river. Its waters abound in fish.

ONGARO, FRANCESCO DALI', an Italian poet and priest, of Hungarian descent, born in Friuli in the early part of the 19th century. At the age of 15 he removed with his mother to Venice, where he found admission into the patriarch's seminary. In 1828-'82 he published poems on Silvio Pellico, which found admirers. Ordination being refused to him at Venice, he removed to Padua, where he attended the university for the purpose of taking orders. In 1833 and 1834 he officiated as professor at Este. Soon, however, he gave umbrage to the ecclesiastical authorities by his occasional sermons, and after his removal to Trieste he ceased to preach. For several years he resided at Trieste, devoted to writing popular songs and class books for Italian pupils in the public schools of that city. In 1848 he returned to Venice, where Manin employed him in missions to Ravenna, and afterward he went with Garibaldi and Mamelli to Rome. Under the short-lived republican government he was a member of the chamber of representatives, and editor of the *Monitore di Roma*. During the defence of the city he was one of Garibaldi's aides-de-camp. After the capture of the city by the French he remained in exile until April, 1859, when he returned to Tuscany. During several years of his exile he was engaged in literary pursuits in Switzerland. Subsequently

he delivered a course of lectures on Dante in Brussels, and resided for some time in Paris, where he prepared for Ristori an Italian version of Racine's *Phèdre*, and of Milman's "Fazio." His popularity is chiefly due to his stirring and picturesque national songs, as his "Phantom Volunteers" and "Garibaldi," published in Milan during the war of 1859. Some of his most celebrated songs are contained in his *Voci del popolo* (Milan, 1860).

ONION (*allium cepa*, Linn.), a well known vegetable belonging to the natural order of *liliacea*, but more particularly to the sub-order *asphodelea*, herbaceous plants with bulbous, fasciculate-fibrous, or tuberous roots, tubular or 6-parted flowers, capsular or berry-like fruit, anatropous or amphitropous globose or angular seeds, covered by a hard, black, fragile integument. The onion has been cultivated from a very remote period, and its native country is uncertain. Beside the onion, the genus *allium* contains many distinct species, such as the shallot, the chive, the garlic, and the leek, which enter into the food of man. They all have bulbous roots, umbellate flowers enclosed in a spathe, sepals and petals spreading, having the stamens inserted in the base, capsular fruit, and angular seeds. The common onion has a ventricose stem, which is leafy at base, terete leaves, a reflexed spathe, flowers in a globose umbel, lobes of the flower obtuse, hooded, not half so long as the stamens, and a flat bulb. The varieties of the common onion are not so numerous as might have been anticipated, considering that it is raised from seed. They vary however in very sensible qualities, such as the hardness of the particular sort, in pungency of taste, in color of the skin of the bulbs, as well as in shape. The most delicate kinds are the Portugal and Tripoli, which are also of good size. The common onion is raised extensively in different sections of New England both for marketing and for exportation. It is found to succeed well as a crop on a rich, moist, sandy soil, using old manures mixed with ashes and soot, or meadow muck mixed with horse, cow, and hog manure. The seed is sown in drill rows about a foot asunder, about the last of May, if the ground be in a proper condition to receive it. As the plants appear they should be kept clear of weeds, and will need 4 or 5 hoeings before the tops arrive at their full growth. The onion requires a full exposure to the sun's rays and all the warmth it can get, so that weeds if suffered to grow would materially impede the progress of the crop by their shading it. Some recommend that the earth be firmly trodden down between the rows, so as to compel the bulbs to become more exposed to the air and light as they increase in size. If the growing plants incline to become thick-necked, or produce scallions as they are called, the more need is there to harden the ground and expose the bulbs. At the end of the season the leaves dry away, when the bulbs should be pulled up

and suffered to lie on the ground, the fibres having by this time decayed and being no longer of any service to their nourishment. By this process, if the weather should prove to be fine and good, the onions ripen and harden. To obtain seed, the bulbs should be planted out early in the spring in beds about 9 inches apart. The tops will appear in a few weeks, and send up several flower stalks from each bulb. They should be kept clear of weeds, and the stalks secured to stakes or protected by some enclosing framework to prevent their being broken by the wind. When the onion is required for early marketing, the seed is sown as a later crop, and the small bulbs protected through the winter, or reset as early as possible. The sorts in most esteem are the Wethersfield red or early red, globular in shape, the mildest and best for the table, and the yellow onion of New York, erroneously called the silverskin. The sorts raised for shipping are the Danvers, a thick-skinned and tough coarse kind, very globular in shape; and the small red, a strong and pungent kind raised for the West India market. For several years the onion crop has been seriously affected by the ravages of the larvæ of a fly, for which no remedy has yet been discovered. A similar insect has been long known in England, and charcoal dust applied to the young growing bulb has there been found of value. This and numerous other applications have in this country hitherto failed.

ONLAF. See AULAF.

ONONDAGA, a central co. of N. Y., bounded N. E. by Oneida lake, and watered by the Oswego, Seneca, and Oneida rivers, and various creeks; area, 720 sq. m.; pop. in 1855, 86,575. Its surface is hilly and broken to the S. and level to the N., and the soil is remarkably strong and fertile. It contains a number of lakes, of which the principal are Onondaga, Cross, Skaneateles, and Otisco. The Onondaga salt springs are in the valley of Onondaga lake, and yield large quantities of salt, amounting in 1858 to 7,088,219 bushels. The agricultural productions in 1855 were 1,015,227 bushels of oats, 182,206 of wheat, 907,458 of Indian corn, 871,785 of barley, 880,141 of potatoes, 68,246 tons of hay, 554,987 lbs. of tobacco, 818,446 of wool, 2,294,287 of butter, and 860,644 of cheese. There were 86 grist mills, 81 saw mills, 6 paper mills, 6 woollen factories, 15 newspapers, 142 churches, and 81,428 pupils attending public schools. The Erie canal traverses the county, connecting at Syracuse with the Oswego canal, which extends to Lake Erie. The New York central railroad passes through the capital, Syracuse, from which various branches radiate.

ONSLOW, GEORGES, a French musical composer, born in Olermont, Puy de Dôme, July 27, 1784, died there, Oct. 3, 1858. His father, who had emigrated from England to America, had returned to Europe during the war of independence, and married a French lady. The son

was educated in London, enjoyed the instruction of several celebrated pianists, and subsequently studied under Reicha in Paris. Some of his quartets and quintets for stringed instruments have become classical. He produced 3 operas, *L'alcade de la Vega* (1824), *Le colporteur* (1827), and *Le duc de Guise* (1837), which are now forgotten. In 1842 he succeeded Cherubini as a member of the academy of fine arts.

ONTARIO, a W. co. of N. Y., drained by the Honeoye outlet, a tributary of the Genesee, Canandaigua outlet, and Mud creek, tributaries of the Clyde; area, 606 sq. m.; pop. in 1855, 42,674. Its surface is hilly and broken toward the S., undulating toward the N., and the soil is generally very fertile. A number of beautiful lakes lie in the county, among which are Canandaigua, Honeoye, Canadice, and Hemlock. Seneca lake lies partly on the E. border. The productions in 1855 were 556,147 bushels of wheat, 617,485 of Indian corn, 525,987 of oats, 320,375 of barley, 188,900 of potatoes, 42,448 tons of hay, 609,075 lbs. of wool, 1,228,097 of butter, and 205,921 of cheese. There were 40 grist mills, 54 saw mills, 4 woollen factories, 5 tanneries, 7 newspapers, 84 churches, and 15,435 pupils attending public schools. The Auburn and Canandaigua branch of the New York central railroad traverses the county, and the Elmira and Niagara Falls railroads connect with it at the capital, Canandaigua.

ONTARIO, a central co. of Canada West, bordering on Lake Ontario, and drained by a number of streams, some of which fall into Lake Ontario on the S., and others into Lake Simcoe, which lies on the N. W. border; area, 851 sq. m.; pop. in 1851, 80,576. The grand trunk railway traverses the S. border; and the Port Hope and Beaverton branch, to Lake Simcoe, crosses the N. part. Capital, Whitby.

ONTARIO, LAKE, the lowest and smallest of the chain of five great lakes of the northern United States and Canada. The name is Indian, meaning beautiful. The lake extends E. and W. about 180 m., having a mean breadth of 35 m., and a depth supposed to average about 500 feet. The elevation of its surface above tide being 234 feet, its bottom is about as far below the level of the ocean as its surface is above it. The area of the lake is computed at 6,800 sq. m., 3,600 sq. m. less than that of Lake Erie, the next larger lake. The boundary line between the United States and Canada runs through the central portion of Lake Ontario, from the mouth of the Niagara river to the outlet in the extreme N. E. corner. This is the St. Lawrence river, which, commencing at this point, pursues a course of nearly 800 m. to the gulf of St. Lawrence. From the head of the river the coast of Lake Ontario on its E. and S. sides as far as Niagara river belongs to the state of New York; thence 50 m. further W. along the southern coast, around by the N. side to the St. Lawrence river, the lake is bounded by Canada West. By reason of its great depth Lake Ontario is much less disturbed by

storms than Lake Erie, and its navigation is also much less obstructed by ice. In the severest winters the boats continue their trips across, and are rarely interrupted by ice. When once chilled, the water slowly recovers a warmer temperature; and even in the middle of May for two successive years, 1837 and 1838, it has been found that the temperature of the water a little below the surface in the central portion of the lake was only from 36° to 38°, while near the American shore it was from 52° to 68°, and at the same times at Coburg on the Canadian side from 48° to 51°. Prof. C. Dewey, by whom these observations are recorded in the "American Journal of Science," supposed that the accumulation of ice in Lake Erie, which frequently does not disappear till sometime in May, serves to retain the low temperature of the water, particularly along the course of the main current through the central part of Lake Ontario. The effect of this is to retard the approach of spring; but opposite causes operate in the autumn to check the advance of winter. The same observer has recorded the measures of the varying level of the lake from the year 1845 to 1859, made at the mouth of the Genesee by order of the government. From these it appears that there is no periodical rise and fall, and the variations are dependent on very regular and adequate causes of supply and drain. The range of rise and fall is 54 inches, the maximum elevation during the years of the observation being in February and the minimum in August. The effect of long continued rains or of long droughts in certain years is observed in the occurrence of the highest or lowest water out of the usual seasons.—The country around Lake Ontario is in general fertile and well populated by agricultural, manufacturing, and commercial communities. On the N. side the surface rises gradually from the lake shore and spreads out in broad plains. From the St. Lawrence river two thirds of the way to the W. extremity of the lake these are underlaid by the lower silurian limestones, from which the soil derives its fertility. These rocks near Toronto pass beneath the group of the Hudson river slates, and these then occupy the surface nearly to Burlington. The red shales and sandstones of the Medina group succeed, and a narrow belt of this formation borders the lake on its W. and S. sides. At Oswego the lower formations begin to reappear, and their outcrops are successively passed over along the E. extremity of the lake. The formations which underlie the lake and form its bottom over the N. half of the lake, at least, are no doubt these lower limestones sloping southwardly from the N. shore. A marked feature in the topography of the S. shore is the "Lake ridge," a narrow elevation ranging from Sodus in Wayne co. to the Niagara river, nearly parallel with the edge of the lake, and at a distance of from 3 to 8 m. from it. Its elevation is in places nearly 200 feet above the lake, and generally exceeds 160

feet. The surface on each side slopes away gradually, so that the line of the ridge is not everywhere distinctly defined. In other places it is plainly marked, having a base from 4 to 8 rods across, and a width at the summit of about 2 rods. Sometimes it is divided into 3 or 4 parallel ridges, which extend a few rods and then unite in one. Being composed of sand and gravel, it makes one of the finest natural roads in the world, and the principal highway along this side of the lake has been upon its summit. There can be little doubt but that this line of elevation was an ancient shore line, and that within a recent geological period it has been formed by the waters of the lake.—Beside its main feeder, the Niagara river, the principal streams which flow into Lake Ontario are the Genesee, Oswego, and Black rivers. The Oswego is the outlet of all the lakes in the western part of New York, amounting to 15 in number. On the N. side of Lake Ontario a range of hills extending parallel with the lake and a few miles back from it throws the drainage generally in other directions. The Trent river alone finds a passage through these hills and flows with a number of smaller streams into the bay of Quinté, a long inlet extending about 70 m. between the peninsula of Prince Edward near the foot of the lake and the mainland. The largest island in the lake, called Amherst island, is at the mouth of this inlet; it is 10 m. long and 6 broad. Many other smaller islands are met with at this lower extremity of the lake; but excepting in this part the coast is very regular and unbroken. The principal towns in New York on the lake, or near the mouths of the streams which flow into it, are Lewiston on the Niagara river, Rochester on the Genesee, Oswego at the mouth of the Oswego river, and Sackett's Harbor near the foot of the lake. In Canada, Kingston at the foot of the lake, Toronto 85 m. from its head, and Hamilton at the extreme head, are the largest towns on the lake. Its navigation is connected with that of Lake Erie by the Welland canal of Canada, 28 m. long, which has 27 locks of 346 feet lift, and is navigable by vessels of 500 tons.

ONTOLOGY. See PHILOSOPHY.

ONTONAGON, the extreme N. W. co. of Mich., bounded N. W. by Lake Superior, and S. W. by Wisconsin, from which it is separated in part by the Montreal river, and drained by the Ontonagon, Fire Steel, Iron, Presque Isle, and Black rivers; area estimated at 2,800 sq. m.; pop. in 1860, 4,570. The surface is hilly, and an elevated range called the Porcupine mountains traverses the northern portion. It contains large quantities of copper and iron ore. Capital, Ontonagon.

ONYX, a variety of agate in which two or more stripes of strongly contrasted colors alternate with each other; often one opaque and one transparent layer. (See AGATE).—In surgery, an abscess of the cornea of the eye, so called from its resemblance to the stone.

OOLITE (Gr. *oolos*, an egg, and *lithos*, a stone), a name given to limestone composed of rounded particles, like the roe or eggs of a fish. Each one of the grains has usually a small fragment of sand as a nucleus around which concentric layers of calcareous matter have accumulated. Ferruginous oolites are also found, as in the Clinton group in the United States, the investing material being in this case red oxide of iron. (For an account of the iron ores, see **IRON**.)—The name oolite is also applied to a group of strata of the jurassic period, largely developed in England, in which limestone of this character occurs. (See **GEOLOGY**.)

OORFA. See **EDUSSA**.

OORT, ADAM VAN, a Flemish painter, born in Antwerp in 1557, died there in 1641. He was instructed by his father, a painter of history, and in early life became distinguished in the same department. Subsequently he opened a school in Antwerp, where Rubens, Jordaens, and other eminent painters were instructed. Intemperate and depraved habits ruined him, and he was finally deserted by all his pupils except Jordaens, who married his daughter. Rubens used to say of him, that if he had studied at Rome he would have surpassed all the Flemish artists of his time.

OPAL, a mineral species presenting many varieties, and known by a number of names, as hyalite, hydrophane, cacholong, girasol or fire opal, precious opal, wood or semi-opal, common opal, &c. The species is recognized by its peculiar vitreous or sometimes resinous or pearly lustre, and by its composition, which is silica combined with $7\frac{1}{2}$ to 11 parts in 100 of water. Its hardness is 5.5 to 6.5; specific gravity 1.9 to 2.8. It is sometimes white, and is also found of various shades of red, yellow, brown, gray, and others. In what is called the precious opal a play of rich colors is exhibited. In fire opal the color is bright hyacinth-red with yellow reflections. The precious opal was known to the ancients, and ranked among the most valuable of gems. Pliny describes it under the name of *opalus*, and in the Orphic hymns it is spoken of as the *οπαλλιος*, and again as *παιδραος* in allusion to the delicacy of its complexion, like that of a child, *παῖς*. Fine specimens of precious opal are still valued as gems, some of the most famous of which will be noted below. Opal in some of its varieties is not a rare mineral. It occurs in veins in porphyry, sometimes associated with galena and blende, and again in vesicular cavities in amygdaloidal rocks, sometimes in limestone and clay slate, and even as the material replacing the organic matter of fossils. It is obtained in various parts of the world. Mines have been worked for it in Hungary, in the county of Sáros, for several centuries, and the precious opal extracted and taken away by Grecian and Turkish merchants has, it is stated, found its way by the Indies to Holland under the name of oriental opal. The same variety is also brought from Honduras and Nicaragua.

The fire opal is found in the Färöe islands, Guatemala, Zimapan in Mexico, Washington co., Ga., and various other places. Humboldt brought from Mexico the first specimens of it seen in Europe. It is too rare, however, to be employed like the precious opal in jewelry. The latter is used for rings, necklaces, and other ornaments, usually in oval or lens form, and to best advantage in a black setting. The edges of the stone on account of its softness are easily injured, and it must therefore be used with care. Very fine jewels are sometimes protected by a thin plate of quartz crystal. Changeable red and green colors are the most highly valued. Some opals are rated at very high prices, as one at £4,000, from Hungary in the great exhibition of 1851, which weighed 526 $\frac{1}{4}$ carats. Two belonging to the crown jewels of France cost 75,000 francs. In the imperial cabinet of Vienna is one weighing 17 oz., of splendid colors, but with numerous fissures. Specimens imported into the United States are valued by dealers at \$4 to \$10 per carat. Some of the finest are from Gracias á Dios, Honduras. The variety called hydrophane is remarkable for becoming transparent when immersed in water. Wood opal is so named from its peculiar ligneous structure, and occurring in the form of trees in trappean rocks. Its localities are Hungary, France, Iceland, Greenland, Maryland, and Pennsylvania. In Vienna it is manufactured into snuff boxes, and when it is in layers with chalcedony it is cut into cameos.

OPATES, or **OPATAS**, a tribe of Indians in the Mexican state of Sonora. They have long been Christianized, are a quiet and industrious people, and are devoted to agriculture. They are found chiefly in the central parts of the state, where they are domiciled in villages inhabited almost exclusively by themselves. This mode of life has given them a fairer complexion than that of the Indians who dwell entirely in the open air. They are the only Indians who have successfully contended with the savage Apaches. On many occasions they have been called out by the government.

OPELOUSAS, the capital of St. Landry parish, La., on Vermilion river, 50 m. W. from Baton Rouge, and 217 W. N. W. from New Orleans; pop. about 2,000. It is situated in the midst of a fertile and picturesque country, and is on the projected line of the New Orleans, Opelousas, and great western railroad. It contained in 1850 a court house, U. S. land office, 2 newspaper offices, 2 banks, and 2 churches (Presbyterian and Roman Catholic), and is the seat of Franklin college, founded in 1839.

OPERA, a species of drama in which airs, recitatives, choruses, &c., with orchestral accompaniments and the ordinary stage accessories, supply the place of spoken words. This is the true opera as found on the Italian stage at the present day, and as performed at the *académie impériale* in Paris; but the term is applied to a class of compositions familiar to the theatres of Germany, France, and Eng-

land, in which the words are partly spoken, partly sung. Opinions, formerly much divided as to its origin, seem now to incline to the belief that the idea of the opera is derived from the Greek drama; and it is said to have become a recognized form of dramatic composition as early as the latter half of the 15th century. There is great doubt, however, whether any work entitled to be called an opera was publicly produced previous to the year 1600, when Ottavio Rinuccini's drama of *Euridice*, set to music by Giacomo Peri, was performed in honor of the nuptials of Henry IV. of France and Maria de' Medici—a conclusion strengthened by Rinuccini's statement in his dedication of the work to the queen, that he had written it "merely to make trial of vocal music in that form." The opera soon became a popular species of musical composition in Italy, and about 1675 was established in the chief cities of the peninsula. In 1646 it was introduced into France by Cardinal Mazarin, but was soon superseded by the national French opera founded by Louis XIV., and which received its impetus from the genius of Lully. This was the parent of the grand French opera of the present day, which is sung throughout. In 1710 *Almahide*, an opera written in Italian and performed by foreign singers, was produced in London; and, notwithstanding the ridicule of wits and men of letters, the popular repugnance to this species of music, and the subsequent competition of the mixed English opera, the Italian opera maintained its ground on the British stage, where it is now permanently established. In Germany it long antedated the establishment of a national opera, in competition with which it still flourishes; and in Russia, the Spanish peninsula, and other parts of Europe, it is the chief form of the musical drama extant. The Italians divide operas into 4 classes, the sacred, the serious, the semi-serious, and the buffo or comic; the French recognize but two divisions, the *grand opéra* and the *opéra comique*, the latter of which is partly spoken; while the Germans subdivide them into grand opera, serious, tragic, heroic, romantic, comic, and other classes. No other nations with the exception of the English can be said to have an established national opera. (See MUSIC.)

OPHICLEIDE (Gr. *οφις*, a serpent, and *κλεις*, a key), a large brass wind instrument of the trumpet species, having a loud tone and a deep pitch, and much used in military bands. It forms the base to the trumpets, and has a compass of 3 octaves, from double Bb to Ab above the line in the base clef.

OPHIDIANS, an order of reptiles. See HERPETOLOGY, REPTILE, and SERPENT.

OPHIR, a name applied first (Gen. x. 29) to one of the sons of Joktan, who are supposed to have made their home in Arabia, and secondly to a region from which the fleet of Solomon brought gold of the finest quality, albugum or almag trees, and precious stones. Although

mentioned together in the Bible, it is now agreed that Tarshish and Ophir are not necessarily in the neighborhood of each other. The precise situation of the latter is a matter of conjecture. Calmet placed it in Armenia, Hardt in Phrygia, Oldermann in Iberia, and others have proposed Carthage, Ormuz in the Persian gulf, Angola, Pegu, St. Domingo, Mexico, New Guinea, and Peru. There are however four theories in regard to its position, which have an appearance of probability: 1. That Ophir was a general name for distant southerly regions, just as we say the Indies for the East. This theory is supported by Father Joseph Acosta, Heeren, Tycheen, and Zenno. 2. That Ophir was on the E. coast of Africa, embracing Nigritia and the Sofala of the Arabians, now Zanzibar and Mozambique. Here have been found mines of gold and silver, which appear to have been worked extensively in ancient times. This theory is supported by Grotius, Huet, Bruce, D'Anville, and others. 3. That Ophir was in southern Arabia, because in Genesis Ophir is spoken of as one of the sons of Joktan who settled between Sabaea and Havilah; because, although no native gold now exists in Arabia, it was anciently found there; and because in the district of Oman there is at present a city of the name of El Ophir, once the seat of considerable Arabian commerce. This opinion has been adopted by Abulfeda, Niebuhr, Volney, Rosenmüller, Gesenius, and others. 4. That Ophir was in India, because that country abounds in the articles mentioned as brought from both Tarshish and Ophir; because several of these articles, such as peacocks and sandal wood, are found nowhere else; because the Hebrew words for apes and peacocks correspond with the words used for the same on the Malabar coast; and because there was in India, in the neighborhood of the modern Goa, a district *Σουπαρα*, called by Arrian *Ουπαρα*, mentioned by the ancient geographers. This theory is maintained by Josephus, Vitringa, Bochart, Reland, Ouseley, and others, and seems to have been adopted by the writers of the Septuagint.

OPHTHALMIA (Gr. *οφθαλμος*, from *οφθαλμος*, an eye), inflammation of the eyes. Under the head of ophthalmia may be included inflammation of all the various structures that enter into the formation of the eye; we shall here however confine ourselves to the consideration of inflammation of the external and visible tissues. Inflammation of the white of the eye assumes a variety of forms, dependent partly on the special character of the inflammation and partly on the constitutional peculiarities of the patient. 1. *Catarrhal Ophthalmia*. Here the eyes are bloodshot, the redness being produced by injection of the network of vessels which covers the white of the eye, and early in the disease is most marked where the conjunctiva is reflected from the lids, while it gradually lessens as we approach the cornea. The lids are swollen, and sometimes the upper lid overlaps

a little the lower one. The patient complains of a feeling as if there were sand or some other foreign body in the eye, while there is a good deal of smarting and itching at the angles of the eyelids and along their free margins. There is at first lachrymation, which is soon followed by the secretion of a thin muco-purulent discharge which accumulates at the corners of the eyes, and which with an increased secretion of the Meibomian glands glues the eyelids together during sleep. The disease may be brought on by irritation or injury of the conjunctiva, though atmospheric influences are its commonest cause. It is ordinarily a mild and manageable complaint, but when severe or badly treated it may produce ulceration of the cornea or leave the lids thickened and granular. In all cases of disease of the eye, absolute rest of the organ should be enjoined, and it should be protected from strong light and heat. In mild cases of catarrhal ophthalmia, rest, a brisk purgative, and the occasional application of tepid water to the eye, are often all that is necessary. If the inflammation does not subside in the course of one or two days, a weak solution of nitrate of silver (gr. ii.-vi. ad ʒi.) may be dropped into the eye once a day, and the eye may be bathed several times a day with a dilute solution of alum or of bichloride of mercury; while at night the edges of the lids may be smeared with dilute citrine or red precipitate ointment. In the severe form, bloodletting, either general, or more commonly by means of cupping glasses to the temples or of leeches, may be required. When the palpebral conjunctiva is congested and thickened, it may be scarified, and after the active inflammation has subsided it may be brushed over with strong nitrate of silver ointment or with undiluted vinum opii. 2. *Egyptian Ophthalmia—Purulent Ophthalmia.* This disease has probably existed at various places and various times under circumstances favorable to its development and propagation, but the attention of the public was first strongly directed to it during the wars of Napoleon, when the British army returning from the expedition to Egypt brought the disease with them and communicated it to other troops with whom they came in contact. The milder cases of purulent ophthalmia differ but little from the severer cases of the catarrhal form of the complaint; there is however even in these cases a very marked tendency to a granular condition of the lids. When the lids are everted they appear velvety, "the enlarged papillæ being separated into groups by furrows and fissures, or tuberculated and sarcomatous looking, like a mulberry." (Jones, "Ophthalmic Medicine and Surgery.") In the severer forms of the disease the eyelids are tense, livid, and often enormously swollen, the upper overhanging the lower one; on separating them they often become everted, from the congested and swollen state of the palpebral conjunctiva. The conjunctiva lining the globe, red and swollen, soon becomes raised up like a wall around

the cornea (*chemosis*); a copious secretion of muco-purulent matter is poured out, runs down on the cheek, and bursts forth when the swollen lids are pressed asunder. The patient is unable to bear the light; there is burning pain in the eye, with pain around the orbit and in the temple, increasing at night. During the violence of the disease fever is present, though commonly moderate in degree. The inflammation is not confined to the conjunctiva, but extends to the sclerotic and the cornea; the latter becomes vascular, opaque, and often ulcerated; sometimes it bursts, discharging the aqueous humor. The disease was first attributed solely to contagion imported by the British troops from Egypt, but it is now certain that it arises sporadically, and that under favoring circumstances, such as over crowding, innutritious diet, or want of cleanliness, it becomes highly contagious. Purulent ophthalmia even in its milder forms requires prompt and decided treatment, both because the disease may at any time suddenly assume a violent and intractable form, and because of its tendency to produce thickening and granulation of the conjunctiva of the lids. When the disease is severe, or when it occurs in a strumous constitution, there is always great risk of permanent injury to the eye; in the worst cases the eye is sometimes destroyed in from 24 to 36 hours. In the severer forms of the disease recourse must be had to bloodletting, either general or by means of leeches or cupping glasses in the commencement; afterward the lids may be pencilled once a day with a solution of nitrate of silver, or brushed over with the lunar caustic in substance, and the eyes should be cleansed frequently with warm water or with a weak warm solution of alum or bichloride of mercury (alum gr. xvi., water ʒ viii., solve; or bichloride of mercury gr. i., hydrochlorate of ammonia gr. vi., water ʒ viii.). To relieve the congestion and swelling of the conjunctiva of the lid, it should be freely scarified, and when great chemosis is present recourse must be had to incision of the ocular conjunctiva. When the inflammation extends to the iris, as evinced by the irregularity and contraction of the pupil and by the change of color in the iris, mercury combined with opium may be cautiously administered, while the pupil should be dilated by the application of extract of belladonna around the eye. On the subsidence of active inflammation the diet should be improved, and iron, bitter tonics, and quinine may be necessary. Gonorrhœal ophthalmia closely resembles the severest and most intractable forms of Egyptian ophthalmia, and is to be treated in a manner precisely similar. Its only cause is the direct application to the eye of gonorrhœal virus. 3. *Ophthalmia Neonatorum.* New-born infants are subject within a week or two of birth to a disease closely resembling catarrhal ophthalmia. The infant is first observed to have the lids glued together after sleep, their edges are red and slightly swollen, and the eyes themselves

are weak and watery. The inflammation is at first mainly confined to the lids; as the disease advances they become swollen, tense, red, and shining; on being separated, a thick, yellow muco-puriform discharge bursts forth, the lids often become everted, and their conjunctival surface is seen to be velvety and of a dark red color; the sclerotic conjunctiva is at the same time seen to be injected, and more or less chemosis is present. In the worst cases the cornea may become ulcerated and the eye destroyed; but if treated sufficiently early the disease is easily subdued. In mild cases bathing and cleansing the eye several times a day with warm water, or with a weak collyrium of alum water, may be all that is necessary. In severe cases the nitrate of silver solution may be applied to the eye daily, while the eye is cleansed 8 or 4 times a day with the alum or bichloride of mercury solution. Sometimes it may be necessary to scarify the conjunctiva of the lids. 4. *Serofulous or Strumous Ophthalmia*.—*Phlyctenular Ophthalmia*. Strumous ophthalmia is eminently a disease of childhood, and, excluding ophthalmia neonatorum, before 12 years of age inflammation of the eye assumes this form in 9 cases out of 10. While it is most common in children presenting other evidences of the strumous diathesis, it is not confined to them, but sometimes occurs in those whose constitutions are apparently without taint. It is early marked by the great intolerance of light which it occasions; the child seeks the shade, shelters the eye with the hand, bends down the head, and keeps the eyelids nearly closed. Any attempt to open the eye is resisted by a spasmodic closure of the eyelids, which the child even if inclined is unable to resist. On forcing them open there is often little appearance of inflammation, merely a faint blush of redness, with perhaps a few vessels running from the angles of the eye toward the cornea. As the disease advances, one or more phlyctenulae form upon the cornea, and these bursting leave small ulcers. Sometimes small fasciculi of vessels may be seen extending toward these ulcers. There is commonly little suffering except from the intolerance of light, and from the excoriation sometimes caused by the tears running down the cheek. The child is fretful, the appetite irregular, and the digestive organs disordered. The disease is apt to be obstinate, with a great tendency to relapse. When ulceration of the cornea occurs, a permanent cicatrix (*leucoma*) is apt to be left. In bad cases the ulceration may penetrate deeply, the cornea be pierced, the aqueous humor discharged, and prolapse of the iris take place. The treatment may be commenced by an emetic of antimony or ipecacuanha (vini antimonii ii., or ipecacuanhae 3i-3ii., every 10 minutes until vomiting is produced); afterward a purgative dose of calomel and rhubarb, or of calomel followed by a rhubarb and soda mixture, may be given. The bowels should be kept open and their secretions regulated by minute doses of hydrargy-

rum cum creta or calomel with rhubarb, soda, and ipecacuanha; and finally sulphate of quinia may be given in doses of from 1 to 2 grains 3 times a day. This last in many cases seems to act like a specific. Iron, in the form of lactate, pyrophosphate, or ammonio-citrate, is often useful in conjunction with the quinine. An infusion of belladonna applied as a wash is frequently of service in relieving the photophobia. Finally, in some cases, counter-irritation by small blisters, applied behind the ears, may be necessary. 5. *Scleritis*.—*Rheumatic Ophthalmia*. Here the inflammation in pure cases is confined to the sclerotic coat, though it is apt to extend to the cornea or iris, or to be complicated with conjunctivitis (catarrho-rheumatic ophthalmia). The redness of the eye is of a pink tint, forming a zone round the cornea when it is most marked, and gradually shading off toward the circumference of the eye, the vessels being minute and disposed in radiating straight lines. The cornea becomes dim, and vessels may be seen encroaching upon its margin to the extent of $\frac{1}{8}$ or $\frac{1}{4}$ of an inch, and then suddenly stopping. The iris becomes discolored and the pupil contracted and sluggish, and sometimes hazy; there is intolerance of light, lachrymation, and dimness of vision. The patient suffers from pain, compared to that of rheumatism, in the temple or around the orbit, which is increased at night and remits toward morning; and there is beside deep-seated pulsatile pain in the eyeball. There is constitutional fever, the appetite is destroyed, and the rest broken. One eye alone is commonly affected, or if both are attacked one is much worse than the other. In mild cases a full dose of calomel and opium may be given at bedtime, followed by a purgative on the following morning; afterward nitrate of potash, in doses of from gr. x. to gr. xx., may be given 3 times a day dissolved in barley water. In severe instances recourse must be had to the abstraction of blood, and small doses of calomel and opium are to be given every night until the gums are slightly affected. Counter-irritation by means of blisters is often decidedly useful; occasionally colchicum has seemed to be of service; the iodide of potassium has likewise been given with success.

OPIE, JOHN, an English painter, born at St. Agnes, near Truro, Cornwall, in 1761, died in London, April 9, 1807. His father was a carpenter, who, intending to bring his son up in his own occupation, strove to repress his natural fondness for painting. Opie, however, pursued his studies without instruction, and had acquired some skill in portrait painting, when he attracted the notice of Dr. Wolcott of Truro (Peter Pindar), who in 1781 brought him to London. There, the circumstances of his early life having become known, the "Cornish wonder," as he was called, soon was an object of popular admiration. So numerous were his visitors and sitters, that frequently the street in front of his residence was blocked up by carriages,

and hardly a year had passed before he had painted the principal nobility. His portraits, remarkable for their vigor and truth, but lacking elegance and refinement, did not long continue to please, and his popularity sank almost as suddenly as it had risen. He had previously earned a handsome competency, and sought to increase it by marrying the daughter of a wealthy pawnbroker; but the match proving an unhappy one, they were divorced, and Opie married again in 1798. Deserted by his patrons, he was not discouraged, but set about correcting his defects, and applied himself also to the study of historical painting, in which he produced several popular pictures, as "The Murder of James I. of Scotland," "The Death of Rizzio," "Arthur taken Prisoner," "Hubert and Arthur," "Belisarius," and "Juliet in the Garden." As his early education had been neglected, he strove to remedy it by studying attentively the best English authors, and mingling in literary society. The professorship of painting at the royal academy falling vacant, he became a candidate for that position, having previously delivered a course of lectures at the British Institution. He withdrew, however, in favor of Fuseli; but on the appointment of the latter to the keepership, Opie was elected professor. In that capacity he delivered in February and March, 1807, four lectures upon design, invention, chiaro-scuro, and coloring, but died before he had completed the course. His lectures, with a memoir of his life, were published in 1809 by his widow. His pictures, though wanting in dignity and grace, are distinguished for their reality and homely truth, and so much for their purity of color, that Fuseli pronounced the coloring in the "Murder of James I." unrivalled among the productions of his contemporaries, and approaching the excellence of Titian. He contributed also to various periodicals articles intended to promote the advancement of the fine arts in Great Britain.—AMELIA, an English authoress, second wife of the preceding, born in Norwich, Nov. 12, 1769, died there, Dec. 2, 1858. She was the daughter of Dr. Alderson, a physician, and in early life manifested a strong taste for literary pursuits. In 1798 she was married to Mr. Opie, and, encouraged by him, published in 1801 a tale entitled "Father and Daughter," which became very popular. Previous to her marriage she had written much, but published nothing except a novel entitled "Dangers of Coquetry," which attracted no attention. In 1802 she published a volume of "Poems," in 1804 the novel of "Adeline Mowbray, or Mother and Daughter" (8 vols.), and in 1805 "Simple Tales" (4 vols.). On the death of her husband, she returned to her father's home in Norwich, where she spent the rest of her life. In the following year appeared "The Warrior's Return, and other Poems," and in 1809 a memoir of her husband, prefixed to his "Lectures on Painting." In 1812 she published "Temper," in 1818 "Tales of Real Life," in 1816 "Valen-

tine's Eve," a novel in 8 vols., in 1818 "Tales of the Heart," and in 1822 "Madeline" and "Illustrations of Lying." Although these works want artistic finish, and the characters lack reality, yet the virtuous principles which they inculcate and the simplicity and ease with which they are told have sufficed to render them very popular. In 1825 Mrs. Opie joined the society of Friends, and in a great measure gave up her literary pursuits, publishing afterward only "Detraction Displayed" (1828), and "Lays for the Dead" (1838), although she constantly contributed to various periodicals. Accounts of her visits to France and Belgium appeared in "Tait's Magazine." Her life has been written by Miss O. L. Brightwell (1 vol. 8vo., London, 1854).

OPITZ, MARTIN, the founder of the Silesian school of German poetry, born in Bunzlau, Silesia, Dec. 28, 1597, died in Dantzic, Aug. 20, 1689. He studied at Frankfort-on-the-Oder and Heidelberg, travelled for some time with a rich Danish friend, and lived subsequently at various petty courts of Germany, officiating also for a time as professor of philosophy and belles-lettres at Weissenburg. He received a wreath of laurels from the emperor Ferdinand II. in 1625, was ennobled by the same monarch in 1629 under the name of Opitz von Boberfeld, and having fled before the horrors of the 80 years' war to Poland, he there became historiographer of King Ladislas IV., and fell a victim to the plague. His poems, embracing didactic, dramatic, and lyric productions, have found numerous editors. His principal merit consists in the introduction of a new prosody into the German poetry of his time.

OPIUM (named by Dioscorides *μυκρωος ορος*, sap or juice of the poppy), a drug prepared from the juice of the capsules of the poppy, *papaver somniferum*. Both the white and black varieties of the plant afford this product, but the opium of commerce is derived chiefly from the former. It is an annual herbaceous plant, growing 4 to 6 feet in height, with a smooth and sometimes branching stem, large leaves, and white or gray flowers. The capsules are smooth, of a rounded form, flattened at the ends, and contain a great number of small white seeds. This species of poppy grows wild in England and in the south of Europe, though supposed to be a native of Asia; and it is cultivated for its opium in Hindostan, Persia, Asia Minor, and Egypt, also in various parts of Europe, for the oil obtained from its seeds and for its capsules. In the United States it is grown only for its ornamental flowers. The process of extracting opium is similar in all countries, and varies but little from the method described by Dioscorides as practised 1800 years ago. It is obtained by incisions made in the unripe capsules a few days after the fall of the flower, care being taken not to penetrate the internal cavity of the shell. A white substance immediately exudes and forms in tears on the edges of the cuts. This is left for 24 hours, when it is

scraped off in brownish lumps, with blunt knives. The peasants who collect it take with it a portion of the epidermis from the capsule, which increases the weight by about $\frac{1}{10}$. When thus gathered it is in a glutinous state, and after being moistened with saliva is pounded in earthen vessels. When of the right consistence it is folded in leaves and ready for the market. Each head yields but a few grains of opium, and but once. The seeds of those capsules which have been cut are good for sowing afterward. In England and France opium has been obtained, which was considered of as fine a quality as that from the East. In India the practice is to cut incisions in the green capsules with a knife of 8 or more blades, which is drawn along them in the hottest part of the day. The next morning the white juice which has exuded and concreted is scraped off. If the dews have been heavy or rain has fallen, the quality of the drug is impaired. The opium when collected is put into jars for transportation to the factories, where it undergoes a process to purify and prepare it for the market. About the end of March, and for some weeks after, these jars begin to arrive at their destination, and the contents are thrown into large vats, from which the mass is distributed to be made into balls. When dry, the balls are packed for sale in chests, in 2 layers of 6 each, with dried stalks, leaves, and capsules of the poppy plant. A chest of Bengal opium contains 160 lbs., and one of Bombay 140 lbs.—Of the several varieties of the commercial drug, that from Smyrna, known as Turkey or Levant opium, is the principal. It comes to us in flattened irregular masses, covered with pieces of dried leaves and the seed capsules of some species of *rumex*. When pure it is of a rich brown or fawn color, has a bitter, warm, and acrid taste, and a peculiar narcotic odor. The interior of the mass is sometimes soft, and by the heat of the hands the whole becomes soft and doughy; but by exposure to the air and to cold it grows hard again and brittle. The smell is peculiar, and to some persons very offensive. Its active properties are extracted by proof spirit better than by either water or alcohol alone, and the tincture thus obtained is laudanum. The composition of opium is exceedingly complicated. Chemists have obtained from it a great variety of active principles and constituents, as may be seen on referring to the analyses of Mulder, Schindler, and Biltz in the *Pharmaceutisches Central-Blatt* for 1837, which are also given by Dr. Hassall in his work on "Adulterations Detected." Other works also, which may be advantageously consulted, are Pereira's "Materia Medica," Brande's "Manual of Chemistry," and Gregory's "Outlines of Chemistry." The most important principles it affords are the alkaloids morphia, codeine, and narcotina. Some of the other constituents are combined with oxygen, and unite as acids with these alkaloids; such is meconic acid. Morphia, which contains in itself more than any other ingredient the active

properties of opium, exists chiefly in combination with meconic and sulphuric acids. It is precipitated from the aqueous infusion of opium, and being purified and separated from narcotina it is obtained in transparent right rhombic prismatic crystals. These dissolve readily in sulphuric, hydrochloric, and acetic acids, and are taken up by 40 parts of cold or 80 of boiling alcohol. Boiling water dissolves only about $\frac{1}{10}$ part of morphia. Opium differs very much in its percentage of this principle; and as on its proportion the value of the drug chiefly depends, it will be seen that great uncertainty must attend its use in medicine. For this reason the salts of morphia are in great part substituted for it. From French opium Pelletier has obtained 10.88 per cent. of morphia, but no narcotina; and other chemists have obtained still larger proportions. The Levant opium averages about 8 per cent. of morphia, and those of India generally less than 8 per cent., and not more than 5.7 of narcotina. From some German opium, made from the black poppy, Biltz obtained from 16 $\frac{1}{2}$ to 20 per cent. of morphia and 6 $\frac{1}{2}$ to 9 $\frac{1}{2}$ of narcotina; but the white poppy of the same species produced 6.8 per cent. of morphia and 33 of narcotina. The proportion of water in the gum is also very variable, and the quantity is often regulated at the will of the dealers. The drug is moreover often imported deprived in part or wholly of its morphia. Beside this, the greatest variety of foreign substances are mixed with it to increase its weight, not only gums and other vegetable matters, the presence of which is partially at least concealed, but also sand, ashes, stones, and even lead. Dr. Pereira mentions that from a sample weighing 10 oz. he extracted 10 drachms of gravel stones.—Of the Constantinople opium there are two sorts, the large irregular flattened cakes, which are of good quality, and the small smooth cakes of a lenticular form, and covered with the poppy leaf; neither of these is equal to the Smyrna opium. The crop of Asia Minor for the year 1860, according to a statement of a correspondent in Smyrna of the "Chemical News," it is estimated will reach 3,600 baskets of 140 lbs. each, the average production being 2,500 baskets. The average export to different countries is given as follows: England, 400 baskets; America, 900; China, 1,000; Java, 500; Borneo, 100; France, 80; Germany, 60. The demand, however, fluctuates considerably with the price, especially for the China market. Of the Indian opium there are 3 varieties, known in commerce under the names of Malwah, Benares, and Patna, the last two being included under the head of Bengal opium. This is exported from Calcutta, the other from Bombay. The exports from the former city are about double those from the latter. The opium trade in India is a strict government monopoly. Any one may engage in its cultivation, but it must all be sold at a fixed price to the government. At Calcutta there are regular periodi-

cal auction sales, which are frequented by purchasers of all races and countries. The East India company exercise extreme care in the inspection of the opium offered for sale, and all that is in any way defective is rejected. The opium when sold is kept in bond by the government until removed to the ship, and is then in the care of a customs officer on board till the vessel proceeds to sea. Of late years, notwithstanding that some opium is furnished by Turkey to the Chinese market, and that the Chinese have themselves largely engaged in the cultivation of the plant, the increased demand for it in the latter country has caused an enormous increase in the imports, affording immense revenues to the Indian treasury. The trade, which commenced with a trifling adventure by the British East India company in 1773, was prosecuted for many years to the extent of only about 1,000 chests per annum, and as late as the year 1820 it did not quite reach 6,000 chests, or about 900,000 lbs. But since that time its progress has been very rapid, till it now amounts to between 10,000,000 and 11,000,000 lbs. annually from India, beside a small amount from Turkey. Since the close of the last century strong efforts have been made by the Chinese government to prevent the introduction of it into their country, and the extent to which this unlawful trade is carried on can only be attributed to the connivance of the officials. The opium is kept on board of receiving ships, as they are called, which lie at anchor, and the smugglers come alongside at night to carry it away. Through the country the laws are equally disregarded, and it seems almost impossible that any legislation can keep out an article so eagerly sought by the people. The cultivation of the poppy in China is carried on principally in the provinces of Yun-nan, Che-kiang, and Ho-nan. The juice obtained is not of the best quality, and is chiefly used mixed with the Bengal or Malwah drug. —Opium is consumed by many eastern nations as a masticatory as well as for smoking, and to some extent in all parts of the world on account of its exhilarating effects, though this practice long continued enervates both mind and body. When taken in small doses it frequently acts as a stimulant, animating the spirit and giving energy to the intellectual powers. To this follows a state of quiet pleasant languor, until sleep succeeds. Unfortunately it is only by increasing the dose that these effects are reproduced, and the habit of opium eating once established is rarely abandoned. Taken in large doses by persons unaccustomed to it, the soporific effects are of longer duration and the symptoms of debility are greater. In medicine, opium was used at a very early period, and is much employed at the present day. It is of incalculable value in its speedy and effectual removal of pain, as well as in the entire cure of many diseases. It is powerful as a narcotic and antispasmodic, and combined with ipecacuanha is successfully employed as a diapho-

retic. Taken in an overdose it will prove fatal. It disagrees with many persons, and the homoeopaths and botanic physicians have introduced several useful substitutes, such as coffee and cypripedium. The homoeopaths also use it in chronic consumption, some cases of apparent coma, suppression of urine, &c. It is used externally in a liquid preparation, and sometimes in the form of a plaster made from the powder.—The importation of opium into the United States for the year ending June 30, 1859, amounted to 71,889 lbs., valued at \$304,910, of which 56,864 lbs. was from England, and 14,941 lbs. from Turkey; and 6,145 lbs., valued at \$22,943, was reexported to Cuba. **OPOBALSAM.** See **BALSAMS**, vol. ii. p. 545.

OPODELDOC, a name given by Paracelsus to a plaster for all external injuries; now applied to a liniment which is much used as an anodyne application in sprains, bruises, and rheumatic pains. It is prepared by dissolving 3 oz. of common soap in a pint of alcohol by the heat of a sand bath, then adding an ounce of camphor, and a fluid drachm each of oil of rosemary and oil of origanum. It concretes into a soft, translucent, yellowish white mass, of the consistency of soft ointment; but it becomes liquid when rubbed upon the skin.

OPOPANAX, a drug formed of the concrete juice of the rough parsnip, *pastinaca opepanax*, brought from Turkey in the form of irregular lumps of whitish and reddish yellow color. Its composition is that of a gum resin with some ingredients intermixed of other character. It was formerly employed in medicine as an antispasmodic and deobstruent; but it is now little used.

OPORTO (Port. *O Porto*, "the port"), a city of Portugal, in the province of Entre Douro e Minho, and capital of the district of Porto, situated on the right bank of the Douro, about 3 m. from the sea, in lat. 41° 8' N., long. 8° 37' W., 175 m. N. by E. from Lisbon; pop. 90,000. It is built partly on level ground along the bank of the river, and partly on the sides and summits of two hills, and has a very beautiful appearance when approached from the sea. On the land side it is protected by a small fort and an old wall flanked with towers; and the entrance to the port is commanded by the fort of São João de Foz on the N. bank of the Douro. A quay extends about 2 m. along the river. On one side of it there is a row of houses, and on the other a substantial wall provided with strong moorings for vessels. A broad, well paved street, with flagged sidewalks, extends to two other good streets, which join it obliquely and lead to the upper parts of the town. The other streets on the declivities are crooked and narrow, but upon the tops of the hills there are several which are spacious and well laid out. There are 11 public squares, the largest of which are the Praça da Constituição and the Campo da Cordaria. The houses are generally well built and whitewashed, and

Oporto is said to be the cleanest town in Portugal. The E. part is built on a steep acclivity, and some of the houses are only accessible by steps cut in the rock. The principal public buildings are 80 churches, including the cathedral, which was originally erected in 1105, but has since been often altered and repaired; the bishop's palace; 15 convents, which are now used for secular purposes; the town hall; the royal hospital; the founding hospital, where from 1,000 to 2,000 children are annually admitted; the exchange; and the opera house. There are several charitable institutions, a library of 70,000 volumes, a mint, a museum, a medical college, an academy of navigation and commerce, a seminary, and several superior and other schools. The English factory is a handsome edifice, with a library and public rooms attached. The town is lighted with gas, and ornamented with many gardens and fountains. It is connected with Lisbon by telegraph. A suspension bridge extends across the river to Villa Nova do Porto, which is chiefly inhabited by coopers and other workmen; and close to it, along the bank of the river, there are extensive vaults for storing wines. The manufactures of Oporto are not of very great importance, and consist chiefly of ironware and casks. Small vessels are built, and there are yards where ships are repaired. The bar at the mouth of the harbor can be crossed at high tide by vessels drawing 16 feet of water. There is a lighthouse at the mouth of the river. The Douro is navigable for barges about 100 m. inland, but it is liable to freshets which sometimes rise 40 feet, and render it difficult to keep the shipping from being swept out to sea by the force of the current. The value of the exports for the year 1858-'9 amounted to \$6,174,547, and the imports to \$6,693,286. The former consisted chiefly of wine, sumach, linen, and fruit. The wine is mostly the red wine called port, and is shipped principally to Great Britain. The imports consist of woollen and cotton goods, iron, hardware, salt fish, hemp, flax, and breadstuffs. In the year 1858-'9 the imports from the United States amounted to \$246,005, and the return cargoes to \$109,292. During the same period 98 steamers and 568 sailing vessels, of an aggregate of 91,870 tons, entered the port. Steam communication is maintained with other Portuguese ports, and with England by a line of British steamers. The roads in the neighborhood are bad, but some public conveyances ply between Oporto and the surrounding towns. In winter the weather is cold and damp, but in summer it is exceedingly warm.—Between the years '716 and 1092 Oporto changed masters several times, being alternately held by the Moors and the Christians; but in the latter year the Christians subdued the city, and have since retained it. John II. conferred many privileges upon the town, which were withdrawn in 1757 in consequence of the people rising to resist a wine monopoly. The French

captured Oporto in 1808, but in the following year Wellington crossed the Douro, and they retired. The town was particularly conspicuous during the revolutionary period of 1820, the long struggle between Dom Miguel and Dom Pedro, when it was alternately the principal seat of both contending parties, and terribly suffered (1828-'33), and again during the revolution of 1847. (See PORTUGAL.)

OPOSSUM, the general name of the family *Didelphidae* of the order marsupials, *le sarigue* of the French. In the present creation they are confined to America, especially to its tropical portions, extending from the middle states to Buenos Ayres on the south, and, with a few exceptions, to the east of the Andes. Some are as large as a domestic cat, but most are no larger than a rat, and many are smaller. The form is rat-like, but the muzzle is longer, ending in a distinct naked muffle; the ears are large, membranous, rounded, and almost naked; the body rather stout; tail generally very long, with only a few minute scattered hairs, except at the root, where it is covered like the body, and powerfully prehensile; the feet 5-toed, plantigrade, naked beneath; all the toes with moderate claws, except the inner one of the hind foot; the hind thumb is distinct, and opposable to the other toes; mammae from 9 to 18, the odd one being in the centre of a ring formed by the others. The teeth are 50; incisors $\frac{1}{1}$, cylindrical, arranged in a semicircle, the foremost 2 the longest; canines $\frac{1}{1}$, the upper the largest; premolars $\frac{3}{3}$, 2-rooted, compressed, and pointed; molars $\frac{3}{3}$, 8-rooted, tubercular, with 5 prickly cusps. The stomach is simple, and the caecum moderately long. They are mostly nocturnal, hiding among the foliage by day, and active at night in search of food. They are divided by Waterhouse ("Natural History of the Mammalia," vol. i., London, 1846) into two sections, according to the presence or absence of the pouch. Among those which have a well developed pouch belongs the common opossum (*Didelphis Virginiana*, Shaw), about 20 inches long to the base of the tail, this being 15 inches additional; the hair is long, soft, and woolly, whitish at the roots and brownish at the tip, giving a dusky color to the animal; long white hairs are mingled with the ordinary fur of the body; face near the snout white, dusky around the eyes; ears black, with the base and margin whitish; legs, feet, and basal portion of tail brownish black. The mouth is wide, the jaws weak, the eyes small and high on the forehead, whiskers stiff, and tail capable of involution only on the under side. The opossum is sometimes active by day, but generally prefers to prowl in bright and still nights around plantations, rice fields, and low swampy places. The gait on the ground is slow, heavy, and pacing, but on trees, to which they take when pursued, their motions are very lively; the sense of smell is acute; it is fond of lying on its back in the sun for hours. It is generally a solitary

animal, unless when bringing up a family. The teeth indicate its omnivorous character; its food consists of corn, nuts, berries, persimmons, roots, tender shoots, insects, young birds and eggs, mice, and similar small quadrupeds; sometimes it will kill poultry, sucking the blood but not eating the flesh, though it is far less mischievous in this respect than the mink, weasel, and skunk; it is very expert in climbing in search of food, hanging by the tail or swinging by means of it from one tree to another. When caught it has the custom of feigning death, and will sometimes in this condition bear considerable torture without exhibiting signs of life, all the time watching its opportunity to bite or escape; when wounded, it is very tenacious of life. Hunting the opossum is a favorite amusement in the South, especially for the negroes, who are very fond of its flesh in the autumn, when it is tender, fat, and flavored like that of a sucking pig; the sport begins after sundown, and is prosecuted with the assistance of a few curs, torches, and axes to fell the trees in which the animal takes refuge; they are easily caught in any kind of trap; many fall victims to wolves, the great horned owl, and other rapacious birds and mammals. The skin is fetid; the hair is dyed by the Indians, and is woven into girdles and other ornaments. When taken young, it is easily domesticated. It is very prolific, bringing forth 12 to 16 at a birth, in the early part of March, May, and July, in South Carolina, and having even a 4th brood further south. The nest is made of dried grass, under a bush or root of a tree, and sometimes the Florida rat or the squirrel is forced to give up its lodging place; the time of gestation is 15 or 16 days; the young when first born are about $\frac{1}{4}$ inch long, blind and naked; the mother places them with her mouth in the pouch, which she holds open with her fore feet, where they soon attach themselves very firmly, each animal to its teat; they grow very rapidly, increasing nearly tenfold in weight during the first week, and are very tenacious of life; when about 5 weeks old, or of the size of a mouse, they leave the pouch, returning to it to suck, or at the approach of danger; they remain with their mother about 2 months; the mother is very fond of her young, which are carried about, twisting their tails around that of the parent, and clinging to various parts of her body; the females are prolific at a year old. This species is found from the Hudson river to beyond the Missouri; it is replaced in Mexico, Texas, and California by the *D. Californica* (Benn.), a smaller animal with a comparatively longer tail, much darker on the body and limbs, the head dusky with a brown streak through the eye, chin and throat sooty, and the ears black. The crab-eating opossum (*D. cancrivora*, Gmel.) inhabits chiefly the northern parts of South America; the color is a nearly uniform brownish black, with the upper half of the tail whitish; the hair is glossy but harsh, very long

(even to 8 inches on the back), and dirty yellowish white next the skin; the total length is about 82 inches, of which the tail is one half. It prefers the swampy regions of Guiana, where small crabs abound, of which it is very fond; it also eats small birds, reptiles, and insects; its flesh is eaten by the Indians, and is said to resemble that of the hare. Several other species of this section are described by Waterhouse.—In the section containing opossums in which the pouch is rudimentary or entirely wanting, the size is smaller, and the young are carried principally on the mother's back, retaining their position by entwining their tails around that of the parent; here also belong about 20 species. Remains of opossums have been found in the calcareous caverns of Brazil, nearly allied to, if not identical with, existing species; Cuvier discovered in the gypsum quarries of Montmartre, of the Paris basin, an almost entire skeleton of a *Didelphis*, which shows the existence of marsupials in Europe in the eocene geological period, contemporaneous with the *Anoplotherium*, *Palaeotherium*, and other extinct pachyderms. There is a web-footed opossum, constituting the genus *Chironectes* (Ill.), in which the hind feet are powerful swimming organs; the fore feet are long, with an elongation of the pisiform bone resembling a rudimentary 6th toe; the females have a perfect pouch; the habits are aquatic. The only species described is the yapock (*C. variegatus*, Ill.) or water opossum; this rare animal has large cheek pouches, and some of the lower molars have their tubercles arranged in a single longitudinal series. The length is about 2 feet, of which the tail is 18 inches, in proportions like the common brown rat; the fur is soft and thick, gray above, with large sooty-black patches, especially on the back, and white below. It is found in Guiana and Brazil. In habits it resembles the otters, with which it was long classed; it is an excellent diver and swimmer, and feeds upon small fish, crustaceans, and other aquatic animals.

OPPERT, JULIA, a French orientalist, born in Hamburg in 1825, of Jewish parents. He received a classical education in his native city, and applied himself to mathematics, and subsequently to the study of law at the university of Heidelberg; but a taste for philological studies induced him to enter at the university of Bonn the courses of Sanscrit under Lassen, and Arabic under Freytag. In 1847 he obtained the degree of doctor of philosophy from the university of Kiel for a thesis on the criminal law of the Hindoos (*De Jure Indorum Criminali*). He next studied the Zend and the ancient Persian, and published a treatise at Berlin on the vocal system of the latter language. His religion incapacitating him for a professorship in a German university, he went to France in 1847, and obtained the professorship of German at the lycées of Laval and Rheims. Some researches on cuneiform inscriptions brought him to the notice of the French insti-

tute, and he was appointed on the scientific expedition sent by the government to Mesopotamia. Upon his return in 1854, he applied himself to decipher the inscriptions, and submitted to the institute a new system of interpretation. He also drew up and laid before the geographical society of the institute a plan of the ancient city of Babylon. He is regarded at present in France as the ablest scholar in the science of comparative philology.—His works are, in addition to the above named: *Les inscriptions des Achéménides* (1852); *Études Assyriennes*; *L'expédition scientifique de France en Mésopotamie* (1854); and *Grammaire Sanscrite* (1859).

OPPIAN, a Greek poet, born in Corycus or in Anazarba, Cilicia, flourished about A. D. 180. He belonged to a distinguished family. His father was banished to the island of Melita for having neglected to pay his respects to the emperor Septimius Severus, when on his progress through Cilicia he made his entrance into Anazarba. The son accompanied him to his place of exile, and there wrote his *Halieutica*, a poem on fishing, in 3,500 verses, which he presented to Caracalla. The emperor was so much pleased with it, that he restored the father to his native land, and gave the poet a piece of gold for each verse, whence they are sometimes called the "golden verses." Oppian died of the plague in his 80th year. A poem entitled *Cynegetica*, "On Hunting," has also been attributed to him, but in the opinion of modern critics was written by another person of the same name, who was born in Apamea or in Pella, Syria, and flourished about A. D. 206. The best edition of the two poems is that of Schneider (Strasbourg, 1776). There is an English metrical translation of the *Halieutica* by Jones and others (Oxford, 1722).

OPTICS (Gr. *τα οπτικά*, from the obsolete *ὀπταί*, to see), the science which treats of the nature of light, and of the laws of the phenomena of light and vision. Investigations, experimental and mathematical, carried on for the purpose of testing questions as to the agreement of the observed phenomena with any theory proposed in relation to the nature, origin, and propagation of the physical cause or agent of light and visibility, belong to and constitute that aspect of the subject known as physical optics. For a consideration of theories of light; the sources, propagation, and diffusion of light; the disposition of the luminous rays within and at the surfaces of media and bodies; shadows; the intensity of light, and its measurement; velocity of propagation; the decomposition of the solar beam, the elementary colors, and colors of natural bodies; the colors of thin films, and their relation to the undulatory theory, and to wave lengths; colors of striated surfaces, diffraction, and interference of light; the changes, by certain media, of refrangibility and color; the persistence of luminous action, as in phosphors; the double refraction and polarization of light; and

certain relations of the solar rays to other physical forces, to organization and life, the reader is referred to the articles ABERRATION, ACTINISM, CHROMATICS, COLOR, DIFFRACTION, FLUORESCENCE, HEAT, LIGHT, PHOSPHORESCENCE, and POLARIZATION. The various optical instruments are treated under their appropriate titles. See also ATMOSPHERE, EYE, HALOS, MIRAGE, RAINBOW, REFRACTION, and VISION. The subject of physical optics is fully discussed, analytically, in Airy's "Mathematical Tracts" (Cambridge, 1858), Lloyd's "Wave Theory of Light" (London, 1857), and Potter's "Physical Optics" (London, 1856; part ii., 1859). The topics remaining to be considered under the present head are chiefly those of the laws of reflection (catoptrics), and of simple refraction (dioptrics), with some further principles relating to the decomposition of light (dispersion), and the characters of the solar spectrum. These form a large portion of geometrical or formal optics, in which, without regard to any theory, or even before its existence, the actual phenomena of light are observed and generalized, and the laws of the changes effected in the rays by surfaces and media are ascertained. In connection with the transmission of light one other general fact may be noticed. It is, that, with the exception that some degree of dimness will arise when the interposed body of air is of great extent, a given surface, as that of the side of a house, illuminated in the same degree, appears equally luminous, at whatever distance it may be regarded. This equal brightness at different distances is readily explained when we remember that the actual intensity of light from a point or unit of surface diminishes in inverse ratio as the square of the distance increases; and that, since any linear magnitude diminishes in the inverse ratio of the simple distance, so a surface must also appear lessened in the ratio of the square of distance; less light comes to the eye from a given surface at increased distance, but the actual surface becomes contracted into an apparent surface less in the same proportion; and thus, one effect balances the other, and the actual illumination is reduced by the effect of the aerial perspective only.—The ancient Greeks and the Arabians made considerable progress in formal optics, but chiefly in the discovery of the law of reflection, and of consequences flowing from it. They had attained the idea of rays of light, the fact of their ordinary straight-lined transmission, and the law of equality of the angles of reflection and incidence, and deduced with much completeness the properties of shadows, perspective, and the convergence of rays by concave mirrors. Euclid and the followers of Plato, however, taught that these rays proceed from the eye, not from the visible object. Aristotle reasoned that an interposed medium was necessary to vision; this he considered to be light, and defined as "the transparent in action." Of special treatises on light, the earliest known are the

"Optics" of Euclid, Hero's "Catoptrics," and Ptolemy's "Optics." In the last of these occurs an elaborate collection of measurements of the refraction at different angles, from air to glass, and from glass to water—tables of much interest, as furnishing the oldest extant example of an accurately conducted physical investigation by experiment. Alhazen, who is believed not to have borrowed from Ptolemy, also gives full tables of refraction. Tycho Brahe introduced a correction for atmospheric refraction into astronomical calculations; the telescope appears to have been invented separately by Metius and Jansen about the year 1600; and Kepler, with his usual fertility of mathematical elements and of hypotheses, and incited by these advances, strove earnestly to find the true law of relation of the angle of refraction to that of incidence, but reached only a near approximation. The actual relation, known as the "law of the sines," was discovered by Willebrord Snell, about 1621. Descartes, who unjustly claimed this discovery, has really the merit of having applied it so as to explain the general formation and the angles of the rainbow. Newton in 1672 published his remarkable discoveries in connection with the decomposition of light by aid of the prism, with the doctrine and measure of the refrangibilities of the different colors, and the agreement of the phenomena with those of the rainbow. His discoveries resulted in improvements in the telescope, and also in explaining a prominent defect in the refracting telescope, that of the colored borders of images, due to chromatic aberration. Dollond in 1757 discovered the possibility of achromatic combinations of lenses, and produced the first of these. The first notice of double refraction is that of Bartholin, 1669; but Huyghens first satisfactorily explained the phenomena, by means of his since renowned undulatory theory of light, his treatise upon which was written in 1678, and first published in 1690. He also first observed the fact of polarization; though the distinct discovery of this phenomenon was not made until about 100 years afterward, namely, by Malus, in 1808, who commenced a thorough study of the subject; and this was much extended by Brewster, Biot, and Seebeck. Hooke appears first to have studied the colors of thin plates, which he described in 1664; and these colors Newton and Young afterward turned to very important use. Diffraction, and the fringes of shadows, were discovered by Grimaldi in 1665; depolarization, with the production of periodical colors in polarized light, by Arago in 1811; the relation of optical properties to the symmetry and axes of crystals, by Brewster in 1818. The general explanation of most of these phenomena by the undulatory theory is due to the labors of Young and Fresnel, in the early part of the present century; and these have since been carried forward and corrected by the labors of Airy, Lloyd, Cauchy, and many others. Still other discoveries in optics,

especially the more recent, as those made in connection with color, the velocity and physical modifications of light, the various optical instruments, and photography, will be found mentioned under the proper heads. I. CATOPTICS. When rays of light fall on a surface of an opaque, and in some degree smooth or polished body, a portion of those rays, greater or less, but never the whole, is thrown off again from such surface, and this light is said to be reflected. Opaque surfaces reflecting in a high degree are termed *specula*, or mirrors. Suppose a ray or minute beam incident on a polished plane surface in any direction whatever, and let fall at the point of incidence a perpendicular to the surface; then, first, it is universally true that the reflected ray will be situated in the same plane in space in which this perpendicular and the line of the incident ray are situated. Thus we may always determine within what plane, vertical to the reflecting surface, to look for the reflected ray. The angle included between the perpendicular and incident ray is termed the angle of incidence; that between the same perpendicular and the reflected ray, the angle of reflection. These angles are always equal. Thus, the fundamental and universal law of reflection from plane surfaces is simply this: the paths of the incident and reflected rays always lie in the same plane with the perpendicular to the reflecting surface drawn to the point of incidence; and in that plane the angle of reflection is always equal to the angle of incidence. This law is strictly verified by experiment and measurement. Necessary consequences of its truth are, that beams or rays parallel before incidence on a plane mirror, will remain parallel after reflection, and that divergent rays will after reflection continue to diverge, and convergent rays to converge, at the same rates as before impinging on the reflecting surface. All the facts relating to images in plane mirrors follow from the same law. But a very important truth in relation to images, and one too often lost sight of, must be premised. Parallel rays or beams of light, or a single beam, may show us the existence of the object emitting them, but they do not enable us to determine its place or distance. We can do this in regard to an object or image, or any point in it, only by means of pencils of light, divergent in themselves, proceeding from the points or point to the eye. We necessarily judge of the size of this object chiefly by the angle subtended at the eye by a line joining its extreme points (the visual angle); and of its distance by the amount of reconvergent action the eye must exert upon the pencils painting its several points, in order to focus them upon the retina, as well as by the convergency of the axes of the two eyes upon the place of the object, if near. (See STEREOSCOPE, and VISION.) Now, the pencils of light from the various points of an object before a plane mirror, being divergent at the same rate after as before reflection,

and the eye of necessity seeing the object in the direction in which the rays of light finally come to it, the image in such case must be, in view of these principles, as it is, seen apparently behind the surface of the mirror, at the same distance as the object is before it, and situated in the course of a straight line let fall from the object perpendicularly on the plane of the mirror, or that plane extended; and it must be erect, but reversed laterally, so that the right side of the object shall show at the left side of the image. If the object be situated at an angle with the mirror surface, its image will form with the surface an equal angle, but in the opposite direction. Hence, with the mirror horizontal, erect objects will be seen in it exactly reversed; and thus is explained the inverted position of the images of trees and banks seen in standing water. When an object is between two plane mirrors nearly parallel, the primary images seen in each of these are reflected as if at a greater distance in the other, and so on, forming in each mirror a long succession of images, growing more and more remote. As the mirrors are turned, approaching a right angle with each other, the number of repetitions grows less, and the whole take a circular arrangement. At a right angle, the object and 3 images are visible, the 4 being at points in the circumference of a circle; at 60° there are 5 images, or 6 forms symmetrically arranged; at 45° , 8 forms, &c. (See KALEIDOSCOPE.) The amount of light reflected from a surface of given size and polish is different with mirrors of different material; and it increases in all cases with increase of the angle of incidence, though not in all cases regularly. We observe the image of the sun in water near midday without difficulty; but when near the horizon the brightness of the reflected light is usually intolerable. Remembering that the surface impinged on by any single ray of light is an extremely small one, it will be seen that any curved reflector is in effect simply a collection of a great number of such minute planes; and that, if we consider the rays falling on such a surface as reflected from the same points in as many different planes tangent to the surface at the points of incidence, we at once extend the law for plane surfaces to all curved surfaces whatever. To the points of incidence of rays on any curved surface, let fall lines perpendicular (normal) to the surface at those points; each reflected ray will be in the plane containing its incident ray and its proper normal; and the angles of reflection and of incidence will be equal for each ray on the two sides of its normal. Ordinary concave and convex mirrors are parts of spherical surfaces. The former must reflect parallel rays convergent, and convergent rays more rapidly so, &c. The latter must reflect parallel rays divergent, divergent rays more so, &c. Parallel rays falling on a concave mirror are reflected to a focus distant from the surface half the radius of curvature of such surface, i. e.,

at $\frac{1}{2}$ the diameter of the sphere; from a convex mirror, divergent at such rate that they appear to come from a point correspondingly distant from the mirror on the other side; this point is then the virtual focus. The focus of parallel rays for the concave mirror is called the principal focus. In fact, this is the focal point only of rays falling on a mirror of small aperture (arc), say not more than 6° . Rays from rings of surface without meet in foci successively nearer to the mirror. This effect is the "spherical aberration" of mirrors. It can only be corrected by resorting to mirrors having paraboloid surfaces; a well known property of the parabola causing all rays parallel with the axis of the mirror to be reflected rigidly to a single focus, and hence all rays emanating from a source of light in such focus to be thrown off in a rigidly cylindrical beam. Hence the use of parabolic reflectors for the lights of lighthouses, locomotives, and similar purposes. The object before a common concave mirror being anywhere without the centre of curvature, the image is between such centre and the focus, inverted, real, and reduced in size; and the places of object and image are interchangeable—the foci are "conjugate," i. e., mutual. When the object is brought within the principal focus, the image is erect, virtual (behind the mirror), and magnified. The image with convex mirrors is always virtual, diminished, nearer the mirror than the object, and erect. II. DIOPTRICS. When a ray or a minute beam of light passes through any surface of division, separating vacuum from any medium, or any one medium from another of different density, or the reverse of either of these cases, a portion of the light is reflected at such surface, and another portion, never the whole, is transmitted. This transmitted light is always bent out of its course at the surface of division, never within the medium, if this be homogeneous; and the light is then said to be refracted. If the medium be one of varying density, like the atmosphere, the ray is bent continually within it; but this case is equivalent to its passing through a rapid succession of surfaces, dividing media more and more or less and less dense. Suppose a ray or minute beam of light transmitted at a point through a plane dividing surface between space and a medium, or any two media, and coming to such point in any direction whatever; let fall to this point of transmission a perpendicular to the surface, and passing through it, so as to lie in both the media; then, first, it is universally true that the ray, after refraction, will be situated in the same plane in space in which this perpendicular and the line of the ray before refraction are situated. Thus we may always determine within what plane, vertical to the refracting surface, to look for the ray after refraction. The angle included between the perpendicular line and the ray before refraction is termed the angle of incidence, and may be represented by I; that between the same per-

pendicular on the other side of the surface and the line of the ray after refraction, is the angle of refraction, R . These angles, the media being of different density, are never equal; nor have the angles themselves any direct ratio to each other. But if in the course of the ray before, and also after refraction, equal radii measured from the point where the ray penetrates the surface be taken, and from the extremities of these radii perpendiculars be let fall on the perpendicular line already drawn, these latter perpendiculars will be the sines of the angles in which they are respectively, *i. e.*, the sines of the angles of incidence and refraction. For any two given media, no matter what the angle of incidence, the corresponding angle of refraction is such that the ratio of the sines is always the same—is a constant value. Thus, the fundamental and universal law of refraction at plane surfaces is also simple, though the conditions to be kept in view are much more complex than in the case of reflection; it is this: The paths of the ray before and after refraction always lie in the same plane with the perpendicular to the refracting surface drawn to the point of transmission, and on opposite sides of that perpendicular; and in that plane, the sines of the angle of incidence and of refraction have in all cases the same ratio for any two given media. This is "Snell's law;" and it also is rigidly verified by measurements. Suppose the refraction be that of a ray passing from air into ordinary crown glass; then, for all angles of incidence, the ratio $\frac{\sin I}{\sin R} = \frac{3}{2}$, very nearly. The angle of incidence is the greater, and the refraction is therefore toward the perpendicular. This is the case whenever the ray passes from a less to a more dense medium. And as, in all such cases, we have $\frac{\sin I}{\sin R} > 1$, this fact of a ratio greater than unity expresses a refraction toward the perpendicular. The value the ratio $\frac{\sin I}{\sin R}$ may have, being constant for any two media, is called for such media the "index" or "coefficient of refraction," c . From air to water, $c = \frac{4}{3}$; from air to diamond, $c = \frac{5}{2}$; from water to crown glass, $\frac{3}{2}$; from crown glass to diamond, $\frac{5}{3}$. When light passes successively from air through water, crown glass, and diamond, these refractions are not added; but the ray has in any one of the media precisely the course it would have had if passed from vacuum or from air directly into the given medium. Thus, in the case supposed, the successive refractions would be $\frac{4}{3} \times \frac{3}{2} \times \frac{5}{3} = c = \frac{5}{2}$, the same as if the light had passed at once from air to diamond; and so in all cases. When the ray passes, on the other hand, from a denser medium to a rarer, we always find the ratio $\frac{\sin I}{\sin R} = c < 1$; and this signifies that the ray is then bent from the perpendicular. Thus, from crown glass to air, $c = \frac{2}{3}$; from water to air, $c = \frac{3}{4}$; and so on. That is, in all these

cases, sine I must be less than sine R ; or sine $R > \sin I$. But the angle of incidence may vary from 0° up to 90° ; and the angle of refraction cannot exceed 90° , because this is the whole space between any surface and a perpendicular to it. Hence, for light going toward the rarer medium, there will be a limit of the angle of incidence beyond which no angle of refraction can be found sufficiently large. Rays meeting the surface at an angle greater than this limit, cannot pass the surface. There is a mathematical impossibility, and hence a physical; and the light is wholly thrown back into the medium, *i. e.*, totally reflected. This total reflection is readily observed on looking in certain directions into a prism; its highly transparent surfaces serve as mirrors for objects situated so that their light falls without a certain angle; for crown glass, $41^\circ 48'$. Any small transparent body of a density unlike that of the medium it is in, and bounded by a curved and a plane or by two curved surfaces, is termed a lens. The forms of lenses, other than the spherical, are: 1, double convex; 2, plano-convex; 3, double concave; 4, plano-concave; 5, meniscus, having its convex more rapidly curving than its concave surface; 6, concavo-convex, having its concavity the greater. Lenses are most conveniently made of glass, and with spherical surfaces. As with mirrors, so with lenses, by considering any curved surface as composed of a multitude of minute plane surfaces, we at once extend to them the law of refraction; and it is then only necessary to know the angles of incidence and the value of c , in order to trace the course of the rays. The refraction toward a perpendicular at the first surface of a lens, will conspire with that from the perpendicular at the second surface, both occurring in the same actual direction in space. A ray passing through the centres of curvature of the surfaces, passes also through the middle point of the lens, and is not refracted. This line is the axis of the lens. Rays parallel to this axis are, when the lens is convex, brought to meet in a real focus lying at some point in the axis; they are made to diverge as from a virtual focus somewhere in this line, whenever the lens is concave. The aperture of a lens is the total arc or number of degrees of curvature of surface on the two sides of the axis, through which light is allowed to pass. Hence, it does not depend on size alone; and the minute lens which is merely a bead of glass has almost necessarily a much greater aperture than a lens of some inches or feet focus. The principal focus of a double convex or double concave lens, of crown glass, of equal curvatures, is at the centre of the sphere of which the lens surface forms part; the focal distance is equal to radius; for the plano-convex and plano-concave, it is equal to twice the radius. The general rule for finding the focal distance is: For the meniscus and concavo-convex lens, divide twice the product of the radii of curvature by their difference; for

the double convex and concave, by their sum. When, for the double convex lens, the object is at any distance greater than twice the radius, on one side, the image is always somewhere between the focus and the other side of the sphere or the distance of twice the radius, on the other; and here, again, the places of object and image are interchangeable; the foci are conjugate. When the object is brought within the principal focus on either side, the image is then on the same side, or virtual, erect, beyond the focal distance, and magnified. So, in the former case, the real image is magnified by bringing the object nearer the focus. The simple act of bringing an object at less than the ordinary distance of distinct vision from the eye, as when we look at small objects close to the eye through a pin hole, increases the visual angle, and so proportionally magnifies them. Hence it is that, for objects viewed as placed within the principal focus, the magnifying power increases with diminution of focal distance of the lens, being determined conveniently by the quotient of the ordinary limit of vision, say 8 inches, divided by the focal distance of the lens. Thus a lens, focal distance $\frac{1}{8}$ of an inch, has a linear magnifying power of $8 \div \frac{1}{8} = 400$ times; and of course a superficial magnifying power of $400^2 = 160,000$ times. Thus are explained the very high powers obtained by the use of minute spherical lenses in form of beads, of perfect glass. But it is only for a small aperture, say 6° or at most 8° , that the rays are brought rigidly to one focus. Enlarging the aperture, the successive rings lying without bring their light to foci successively nearer the lens; passing their foci, these rays diverge, and form an indistinct border of light about the image. This is spherical aberration of lenses. It is to some extent corrected by peculiar forms of lens, hence called aplanatic; the least spherical aberration thus obtained is with a double convex lens, the radii of whose curvatures are as 1 : 6; this, with the surface whose radius is 1 toward the object, gives an aberration of $1\frac{1}{7}\pi$ times its own thickness.

III. DISPERSION. The dispersion of light is the separation of the colors existing, actually or potentially, in white or solar light. It may occur by refraction, by diffraction, or by interference. (See COLOR.) The total length of spectrum obtained by prisms, *i. e.*, the total dispersion, and also the amount of spreading out of the different colors, differ with the nature of the medium or prism employed. Calling the refrangibility of the violet ray V' , and of the red R' , for a given prism, and the coefficient of refraction c , the dispersive power is
$$= \frac{V' - R'}{c - 1}.$$
 This ratio, for oil of cassia, is .189; for flint glass, .052; Canada balsam, .045; diamond, .038; crown glass, .036; water, .035; rock crystal, .026. Thus, for example, the total dispersion and length of spectrum for a hollow glass prism filled with oil of cassia, are about 4 times those of crown glass; and of

flint glass, $1\frac{1}{4}$ times those of crown glass. Now, lenses, like prisms, must disperse or decompose light. The different colors are really brought to foci that, in the case of convex lenses, lie in the following order: the focus of the least refrangible or red ray corresponds with the true place of the principal focus; and the more refrangible rays are brought to foci within this, as the orange, yellow, green, blue, indigo, and violet, lying nearer and nearer to the lens. These colored rays cross at their foci, and again diverge; the effect is a colored border or fringe, mainly blue or red, as the case may be, surrounding the image, and more marked as the aperture of the lens is greater, and in objects toward the margin of the field of view. This is chromatic aberration of lenses. It is almost perfectly corrected by combining lenses in various ways, thus forming achromatic combinations. The principle of these is usually that of correcting, for example, the less dispersion of crown glass by the greater dispersive power of flint glass. To do this, a concave of flint of less entire curvature is combined with a crown glass, convex, and of the greater entire curvature. The dispersion is corrected; but part of the refractive or lens effect remains undestroyed, and the focal distance becomes greater. The solar spectrum is not a succession of colored rays merely. In the lower half of the spectrum, not in the upper, that is, from the green down through yellow and orange to red, the thermometer is more and more affected; and with some sorts of prism, it rises highest in the dark space without the red ray. So, from the green space up through blue and indigo to violet, the sensitized surface of a plate prepared for photographic purposes is more and more speedily and powerfully affected; and with some sorts of prism this effect is greatest in the dark space beyond the violet. Thus, there are three overlapping spectra; that of heat rays being generally lowest or least refrangible; of color, intermediate; of photogenic or actinic rays, highest or most refrangible; and the first and last of these, always present, being invisible. In 1802 Dr. Wollaston discovered in the spectrum 8 or 4 fixed dark lines, or minute straight bands crossing the colored spaces transversely. These lines were rediscovered by Fraunhofer of Munich, and increased by accurate observation to a number that, according to the state of atmosphere or medium, and other circumstances, varies from 600 to 2,000. These occur in fixed positions in certain colors; and hence, certain prominent ones, marked A, B, C, D, E, F, G, have been used to determine the position and refrangibility of the colored rays. The lines are doubtless due to interferences of rays. The different fixed stars have each its own system of dark lines, unlike that of solar light; though, singularly enough, Sirius and Castor give the same system. The electric light and artificial light give various systems of bright bands or lines. Kirchoff (1860) finds that a candle and all so-

dium flames give a double bright line corresponding to the double dark line, D, of the solar spectrum. He finds that, passing the sodium-flame light through another sodium flame, the lines become dark, as in the case of solar light. Hence, he concludes that the bright D proves the presence of sodium in a source of light; and the dark D of sunlight, the presence also of sodium in the sun's atmosphere, the darkening being due to interference. So, Brewster's bright lines, A, a, B, with a salt-petre flame show potassium; and this is also in the sun's atmosphere. The lines corresponding to lithium are not found. Thus is opened a new field of inquiry of the highest interest; and further results are promised.

OPTIMISM, in philosophy, that doctrine according to which this world, considered as a whole, is the best that could have been made. Its imperfections are more apparent than real, as the evils existing in the world are only evils when viewed by themselves, and when considered in relation to the whole subserve the general good. The doctrine was usually stated in this form: if this world were not the best, God either did not know a better one, or was unable or unwilling to create it; none of which suppositions can be true, as in that case his omniscience, omnipotence, or benevolence would be impugned. The doctrine was first fully developed by Leibnitz in his *Theodicea*, who however conceived the world to be in a progressive state, and constantly advancing toward greater perfection. Optimism was made the subject of boundless ridicule by Voltaire in his *Candide*. Dugald Stewart affirms that the optimism of Plato differs from that of Leibnitz in not leading to a denial of the freedom of the will, every thing being right so far as it is God's work, the sins of free moral agents and the evils in the world being no serious objections to the perfection of the universe, as our view is now only limited and narrow. Optimism in some form has been held by the best philosophers of all ages; by the followers of Plato, the stoics, and the Alexandrian school in antiquity; and by Anselm and Aquinas in the middle ages; but it was most fully developed by the schools of Descartes and Leibnitz in modern times.

OPZOOMER, CAROLUS WILHELMUS, a Dutch philosopher and publicist, born in Rotterdam, Sept. 20, 1821. He studied at the university of Leyden, and while there wrote a "Letter to Da Costa," and "Examination of the Dutch Annals of Theology," in both of which he attacked the principles of Christianity. In 1846 he became professor of philosophy in the university of Utrecht, and in 1848 member and secretary of a royal commission to reform the constitution of the universities. In this position he advocated the merging of the three universities into one; and when the proposition was given up on account of the opposition manifested by the institutions themselves, he published his plan under the title of "Project of a Bill for the Reform of the Universities."

He wrote a political treatise "On Direct and Indirect Elections;" and among his philosophical writings is *De Weg der Wetenschappen* ("The Path of Knowledge," Utrecht, 1851; German translation, 1852), a work on logic, in which he advocated the most absolute rational empiricism, and sought to introduce into ethics the method of the natural sciences. Of his other works, an *Oratio de Philosophia Natura* (Utrecht, 1852), "Conservatism and Reform" (1852), and a "Commentary on the Civil Code of Holland," are most noteworthy.

ORACLE (Lat. *oraculum*), in ancient religion, a revelation believed to be made by some divinity in reply to the questions of men; applied also to the sacred place or establishment where such revelations were communicated. The responses were given either by the mouths of priests or priestesses, or by other signs. They were usually uttered in a state of delirium (*furor diuinus*) or divine inspiration, and they consisted often of incoherent words. When the presages were given by signs, the oracles rank only among methods of divination. Thus the responses of the oracle at Dodona were given either by the movement of leaves, the noise of brazen vessels, or the murmuring of the waters of a fountain. The sibylline oracles, or the books containing the words of the sibyls, were consulted at Rome only by order of the senate and in presence of a magistrate. It was not unusual to attribute to the shades of the dead the power to return and unveil the future to mortals. The art of evoking them, called necromancy, existed among the Hebrews, Thracians, Greeks, and Germans. That sacerdotal fraud played some part in the ancient oracles is not doubted. The hollow statue at Antioch, the speaking head in Lesbos, and the Theraphim, or embalmed and speaking heads mentioned by the rabbis, are among the instances of deception. But the probable origin of oracles, and the cause of the faith in them, was the belief that the involuntary utterances of a person suffering under hallucination, and also other accidental noises and movements under certain circumstances, proceeded from some divinity. Chance was thus made a manifestation of the will of the gods. Springs, fountains, grottos, and caves, the waters of which were discovered to have delirious or narcotic effects, were therefore selected to be the sites of oracles. Thus at Didyma the vapor of the water affected both the priestess and the person who came to consult her; at Colophon, the priest drank of the water of a secret well in a cavern; and at Delphi, of the fountain of Castalia, while a vapor issued from a cavern beneath the tripod. In some of the oracles artificial fumigations were employed. Most of them claimed to have been founded either by a divinity or famous diviner, and possessed a body of mythical traditions. Oracular responses were usually given in Ionic hexameters, though, to avoid the scandal which followed when the god of verse ex-

hibited metrical defects, they were subsequently in prose. They were in general remarkable for obscurity and equivocation, yet they exerted great political as well as religious influence. The priests were often accomplices of the statesman, and the responses of the Pythia were not authoritative till they had been written and interpreted by the presiding officer. Delphi, which was the common centre of all the oracles of Apollo, thus became the religious and political metropolis of Greece, extended its authority over the Romans after their conquest, and was called by Cicero *oraculum orbis*. Its power has been likened to that of the Vatican in the middle ages. Oracles were sometimes fabricated or modified after the event, the most remarkable example of which was the sibylline predictions which Christians of the 2d century produced in order to convince pagans that the coming of Christ had been foretold even by their own gods. Even while they were in the highest popular repute, oracles were sometimes condemned by the learned. Aristophanes made them objects of raillery; Demosthenes accused the Pythia of favoring Philip; and Cato of Utica disdained to interrogate Jupiter Ammon. Eusebius counts 600 authors who had assailed them. The Neoplatonists referred the origin of oracles to demons, and Plutarch explained by the death of demons the cessation of some of the oracles. The theurgists sought to revive them and to oppose their power to Christianity. Julian vainly attempted to restore the faith in them. The early Christians explained their predictions also by the agency of demons, whom they identified with fallen angels, the associates of Satan. Eusebius and others affirmed that they became silent at the birth of Christ, and assigned as the reason that Christ put an end to the power of Satan on the earth, and to the worship offered him under the name of God by the gentiles. This view prevailed for many centuries. The Urim and Thummim and the Bath-kol (literally, daughter of the voice, echo) of the Jews have been supposed by some critics to resemble the heathen oracles.—Among the Greeks, Jupiter was less frequently regarded as the source of oracular revelations than Apollo. There were 23 oracles for the consultation of the latter divinity, the most important of which was at Delphi. (See *DELPHI*.) The principal others were that at Abœ, highly esteemed by the Phocians, which promised the victory to the Thebans before the battle of Leuctra, and which, though burned by Xerxes, retained its power, and was in repute as late as the reign of Hadrian; that of the Branchidæ at Didyma, which combined purifying or atoning rites with the practice of responding, was administered by a family having the hereditary gift of prophecy, received from Croesus as rich presents as that at Delphi, and was burned by the Persians, but continued to be consulted; that at Claros, in the territory of Colophon, the responses of

which were given through an inspired prophet, and which was consulted even under the Roman emperors; that at Ismenion, in Boeotia, the national sanctuary of the Thebans, which interpreted signs instead of speaking from inspiration; that at Patara, in Lycia, where the prophetess was obliged to wait a whole night in the temple before making communications; and that at Telmessus, also in Lycia, attached to a fountain, the priests of which interpreted dreams and other marvellous events. The most important oracles of Jupiter were at Olympia in Elis, and Dodona in Epirus, at both of which he only sent signs for men to interpret. A victim was offered at Olympia by those who came for consultation, and the priest divined from accidental circumstances attending the sacrifice. This oracle was chiefly designed for those intending to take part in the Olympic games. That at Dodona was one of the most ancient and celebrated. The response was given in sounds produced by the rustling of the wind in an oak tree ("the speaking oak"), which were interpreted in early times by men, but afterward by old women. It was esteemed for impartiality and for being inaccessible to bribes, but early declined in importance. Its sacred oaks were cut down and its temple demolished by the Ætolians in 219 B. C., but it was consulted until the 8d century A. D. There was also an oracle of Jupiter Ammon in Libya, said to have been founded by Egyptians from Thebes, which was first made known to the Greeks by the Cyreneans, and was afterward frequently interrogated by them, but was in decay in the time of Strabo; numerous priests were in attendance. The other divinities were consulted by oracles only on the special departments over which they presided. Thus, Ceres foretold at Patræ in Achaia the fate of sick persons by means of a mirror suspended in a well; Mercury was consulted at Pharsæ in Achaia, the person going away after a ceremony, and accepting the first remark that he heard from any one as the response of the divinity. There was an oracle of Pluto and Proserpine near Nyssa in Caria, at which priests divined concerning the remedies for illness by passing a night in a sacred grotto, where they often took their patients with them, who would themselves fall into a prophetic sleep. To other persons the place was fatal. An annual festival was celebrated there, the young men driving into the cave a bull, which immediately fell dead. Heroes sometimes acted as mediators to reveal the will of Jupiter to men. The spot near Thebes where Amphiaraus was said to have been swallowed up was the seat of an oracular sanctuary. Birds never alighted there, and cattle never grazed in the neighborhood. After a fast the inquirers slept in the temple, and received the revelations in dreams. If they recovered, they were obliged to drop some money into the well of Amphiaraus in the interior of the shrine. Pausanias calls the oracle of Amphilochus, at Mallas in Cilicia, the most

trustworthy known in his time. The oracle of Trophonius, at Lebadea in Boeotia, was held in the highest esteem until a very late period. Several days of preliminary purification were required before consultation, and during the sacrifices a soothsayer explained from the signs whether the hero would admit the inquirer. If allowed, the latter went into the cave of Trophonius, was received by two boys and bathed in the river Hercyna, and then drank in succession of two wells, one of which made him forget all his former thoughts and the other prepared him for the visions which he was about to have. He then descended by a ladder to the bottom of the cave, and various reports were made of what was there seen, and the responses of the priests were modified according to these reports. Apollonius of Tyana passed 7 days in this cave. There were numerous oracles of Æsculapius, the most celebrated being that of Epidaurus in Argolis, the temple of which was inscribed with the names of persons who had recovered by remaining there one night. It has been asserted that animal magnetism must have been known to the priests of Æsculapius. Oracles where divination by necromancy was practised existed near Lake Avernus in Italy, and at Heraclaea on the Propontia. In Italy there were no oracles where the priests spoke by inspiration. The principal Roman oracles were those of Faunus in the grove of Albunea and on the Aventine hill, where the inquirer received his answer in sleep in prophetic visions; those of Fortuna, where the responses were given by lot; and that of Mars, which in early times existed at Tiora Matiene, and at which the revelation was given through a woodpecker.

ORAN, a province of Algeria on the Mediterranean, extending 180 m. from the mouth of the Shelliff to the Wady-Ajerud, and bounded N. E. by the province of Algiers, S. and S. W. by the Atlas mountains, and W. by the empire of Morocco; area, 88,899 sq. m.; pop. 600,000, one half of whom are Arabs; European pop. in Dec. 1857, 55,740. The province is subdivided for administrative purposes into the departments of Oran, Mostaganem, Tlemcen, Mascara, and the Sahara tribes. It has two principal hill ranges, the Jebel-Beni-Smiel, and Chareb-el-Rieh. The rivers have a course generally from E. to W., and near the capital there is a considerable sheet of water called Lake Sale or Sebka. A great part of the soil is fertile, and there are large tracts covered with forests. The temperature is in general higher than that of the other provinces of Algeria, but it is somewhat moderated by steady N. W. winds.—ORAN, the capital, is situated on a bay of the same name, 209 m. W. S. W. from Algiers; pop. in 1857, 27,269, of whom 19,288 were Europeans. It stands on both sides of the mouth of a small stream called the Oued-el-Rakhi, and at the foot of the peak of St. Croix or Mergiaigio. It is well fortified, and in general well built. The principal edifices are

a mosque, now converted into a parish church, another church built by the Spaniards in the time of Charles V., a hospital, a castle, and an arsenal. It is badly supplied with water, and the country around is arid and barren. The climate, though intensely hot, is generally considered healthy. There is no good anchorage immediately around the town, but Mers-el-Kebir, 8 m. distant, has a large and commodious harbor, which has recently been greatly improved. There is a considerable trade, the aggregate value of the imports and exports being about \$3,500,000. Oran was long a subject of contention between the Spaniards and the Moors. The former, under Cardinal Ximenes, took it in 1509, and retained possession of it till 1708, when the Algerines expelled them. The Spaniards regained it in 1732, but subsequently restored the town, retaining only the port and castle of Mers-el-Kebir. In 1830 the French took possession of it.

ORANGE, a well known fruit produced by a tree of the natural order *aurantiaceae*. This order is composed of trees or shrubs having dotted leaves; fragrant and handsome flowers, the calyx urceolate or campanulate, short, 8 to 5 toothed, withering; petals 3 to 5, broad at base; stamens equal in number to the petals, or twice as many, or some multiple of their number, inserted upon the same hypogynous disk; ovary free, many-celled; fruit pulpy, of one or more cells; seeds attached to the axis, one or many, without albumen; embryo straight; cotyledons thick and fleshy, and radicle very short. The genus *citrus*, to which the orange and lemon belong, is very subject to an unusual and abnormal growth of the carpels, which results in what are called horned and fingered fruits. The genus is almost entirely East Indian; the wood of the several species is hard and compact; their leaves abound in a volatile, fragrant, bitter, exciting oil; the pulp of the fruits is always more or less acid. Among the most remarkable products of the order are the citron, lemon, lime, pomelmooose, shaddock, and orange. The common sweet orange (*citrus aurantium*, Risso) is found upon the hillsides in the forests of the Himalaya, and in China. This species is extensively cultivated for its delicious fruit and for the purposes of commerce. It may be considered a small tree or shrub with an arborescent stem; ovate oblong, acute leaves, a little serrulated, with the petiole more or less winged; its flowers white; its fruit roundish, seldom pointed, occasionally mammosc, many-celled, golden yellow or tawny, the pulp sweet, refrigerant, the rind smooth or smoothish, aromatic, and the oil cysts convex. The principal varieties of the common sweet orange are the China orange, with round, smooth, rather flattened fruit, and a thin golden rind; the orange of Nice, with large, thick-skinned, rough, dark yellow, round fruit (this is one of the finest in every respect); the St. Michael's orange, with small, round, pale yellow, seedless fruit, a thin rind, and extremely

sweet pulp; the sweet-skinned orange, or "forbidden fruit" of the Paris shops, with a subacid and pleasant pulp, and a yellow, soft, and fleshy rind; the blood orange, with round, rough, reddish yellow fruit, and the pulp irregularly mottled with crimson; the mandarin orange, with flattened, rough, deep orange fruit, and thin rind, which separates spontaneously from the pulp (a kind in such esteem in China as to be employed for presents to the officers of state, whence its name); the ribbed orange, with a flattened, ribbed, deep yellow fruit, of little value; the pear-shaped orange, a rare and curious sort, with round, smooth, rather flattened fruit, and thin, golden rind; the fingered orange, its fruit ovate, with an occasional lobe or horn from the monstrous growth of a carpel; and the egg oranges of Malta. The Seville orange (*C. bigaradia*, Risso), or bitter orange, is a smaller tree with spiny branches, elliptical, acute leaves, winged petioles, snow-white flowers, middle-sized, roundish, smooth, or wrinkled fruits of a deep yellow color, and the oil cysts upon the rind concave. From this species the orange water of the perfumers is chiefly obtained; the flowers yield the oil of Neroli; the fruit, whose pulp is bitterish and acid, when crushed and boiled in sugar makes marmalade. There are numerous varieties of the bitter orange, some of which are cultivated exclusively for their flowers, which are large, showy, and fragrant. Of these is the curled-leaved bigarade, with flowers growing in thick clusters at the ends of the branches. This is the nosegay plant, or *le bouquetier* of the French gardeners, and is a common object of cultivation all over the south of Europe. The double-flowered bigarade is also a great favorite in gardens on account of its numerous fragrant flowers, which do not so readily fall to pieces as the single kinds do; the soil in which the plants are grown must be kept very rich, however, to secure the double flowering condition. The myrtle-leaved bigarade has a very dwarf habit, and when well cultivated its beauty is remarkable in the contemporaneous appearance of fruits and flowers; it is said to have originated in China, and to be there used instead of box for edgings to garden beds. The bizarre bigarade is a singular variety with purplish white flowers, and different shaped and different flavored fruits, being of that class of freaks or sports in vegetation which are observable in other plants, and which require care in propagation to preserve them. The bergamot orange (*C. Bergamia*, Risso) is a tree rather variable in its appearance; its branches are brittle; its leaves are oblong, dark green above, but paler beneath; its flowers small, white, very sweet smelling; its fruit pear-shaped, smooth, pale yellow, oil cysts of the rind concave, pulp subacid and very fragrant. From the fruit and flowers of this species is procured the oil of bergamot; the rind retains its perfume for a long time after it has dried; it is pressed into moulds to form

little boxes to contain sweetmeats and lozenges. A variety with ribbed fruit having a broad scar on its summit is the *mellarosa* of the Italians, and is much esteemed on account of the abundance of its flowers.—In cultivation, the common sweet orange is raised from seeds, cuttings, layers, grafts, and buds. When reared from the seed, usually many years are requisite to bring it into bearing, though cramping the roots in small pots and feeding highly with manure may hasten the period of fruiting. The usual mode is therefore by grafting upon seedling stocks; and the bitter orange, being a stronger grower, is employed to graft upon. The lemon tree is also used, and the slit method of grafting pursued with success. Well developed axillary buds inserted in young seedlings, whenever their bark readily peels, do equally well. Planted in the border of the conservatory, the orange tree flourishes, but the usual mode in colder countries is by planting it in tubs or in large wooden boxes. In the vicinity of Florence in Italy, the Seville or bitter orange does well in the open air; and trees of it in the gardens are resplendent in the month of January for their green leaves and golden fruits. The sweet orange trees, however, are not exposed to the frost, but are artificially protected in various ways in the winter months. The usual mode of growing them is in large earthen pots, which are preferable to tubs or wooden boxes; and the branches are suffered to spring from the crown of the roots so that the form of each plant may be that of a bush, which is more beautiful as well as natural. Loudon informs us that the orange was introduced into England in 1595 and grown against walls, and for many years bore fruit. In that country the cultivation of both the orange and the lemon has been successful by the same process revived, after it had fallen into disuse; and in Paris the same has been effected by standard trees in the open air, enclosing them with double glass cases about the month of September, and covering the outer lights with mats in the severest weather. After the wood has perfectly ripened, continued darkness for a considerable period does not seem to be injurious to the tree. The beauty of orange blossoms, employed in making up winter bouquets and for bridal wreaths, renders the cultivation of the orange tree desirable, especially in the northern states, and the greenhouses and conservatories there contain many varieties. A warm, rich, and well drained soil seems best fitted for successful growth, and upon these the perfume and juiciness of the fruit and healthy vigor of the foliage depend. The largest supplies of oranges in commerce come from S. Europe, China, the Azores, and the West Indies. In the United States the orange has been successfully cultivated in Florida; and the orange, lemon, and lime are commonly cultivated in the warmer parts of the southern states, while the bitter sweet orange (*C. culgaris*, Risso) is completely naturalized in some

parts of South Florida.—The importation of oranges into the United States during the year ending June 30, 1859, amounted to \$644,688, of which \$542,642 worth were from the Two Sicilies, and the rest chiefly from the West Indies and the Pacific islands.

ORANGE, the name of counties in 7 of the United States. I. An E. co. of Vt., bordering on N. H., from which it is separated by the Connecticut river, and watered by various small streams; area, about 650 sq. m.; pop. in 1850, 27,296. It has an uneven surface, and toward the N. is mountainous, the eastern range of the Green mountains crossing the N. W. part; the soil is moderately fertile. It contains great quantities of iron ore and granite and some lead ore. The productions in 1850 were 176,586 bushels of Indian corn, 52,822 of wheat, 169,587 of oats, 599,925 of potatoes, 70,549 tons of hay, 248,715 lbs. of wool, and 869,042 of butter. There were 2 woollen factories, 2 foundries, 4 flour, 2 paper, and 13 saw mills, 11 tanneries, 8 newspaper offices, 64 churches, and 9,212 pupils attending public schools. The Connecticut and Passumpsic rivers railroad traverses the eastern margin, and the Vermont central crosses the S. W. corner. Capital, Chelsea. II. A S. E. co. of N. Y., bordered S. W. by N. J. and E. by the Hudson river, and drained by the Wallkill and Shawangunk rivers; area, 888 sq. m.; pop. in 1860, 63,814. The Shawangunk mountains cross the N. W. corner, and a range of precipitous bluffs, having an elevation of from 1,000 to 1,500 feet and known as the highlands, are toward the S. E. on the Hudson river. The remainder of the surface is chiefly rolling upland. It is noted for its excellent grazing and fine dairy produce, nearly half the improved land being in pasture. The productions in 1855 were 48,895 bushels of wheat, 857,490 of Indian corn, 291,111 of oats, 202,801 of rye, 123,551 of potatoes, 103,211 tons of hay, 8,285,587 lbs. of butter, and 80,660 of cheese. The milk sold amounted to 4,553,514 galls. There were 4 cotton factories, 3 paper mills, 8 woollen factories, 21 saw mills, 88 grist mills, 12 tanneries, 112 churches, and 21,575 pupils attending public schools. The New York and Erie railroad passes through the county, Goshen, one of the capitals, being on the line, and the other capital, Newburg, connected with it by a branch. III. An E. co. of Va., bounded N. W. by the Rapidan and drained by branches of the North Anna river; area, about 250 sq. m.; pop. in 1850, 10,067, of whom 5,921 were slaves. Its surface is somewhat hilly, and the soil generally fertile. The productions in 1850 were 121,825 bushels of wheat, 267,140 of Indian corn, 80,750 of oats, 1,881 tons of hay, 174,700 lbs. of tobacco, 21,509 of wool, and 54,814 of butter. There were 23 grist mills, 16 saw mills, 5 tanneries, 1 woollen factory, 9 churches, and 253 pupils attending public schools. The value of real estate in 1856 was \$2,748,666, showing an increase of

85 per cent. since 1850. The Orange and Alexandria railroad intersects the county, passing through the capital, Orange Court House. IV. A N. co. of N. C., watered by the head waters of the Neuse and several small streams; area, about 700 sq. m.; pop. in 1850, 17,055, of whom 5,244 were slaves. It has an undulating surface and fertile soil. The productions in 1850 were 98,888 bushels of wheat, 459,088 of Indian corn, 106,840 of oats, 2,805 bales of cotton, and 194,275 lbs. of tobacco. There were 5 grist mills, 2 saw mills, 4 tanneries, 2 newspaper offices, 29 churches, and 4,220 pupils attending public schools. The North Carolina railroad intersects the county, passing through the capital, Hillsborough. V. A central co. of the peninsula of Fla., bounded E. by the St. John's river; area estimated at 2,000 sq. m.; pop. in 1850 (since which it has been reduced by the formation of other counties), 466, of whom 226 were slaves. It has a level surface covered with extensive pine forests and savannas, with many small lakes and swamps interspersed. Capital, Moultrieville. VI. A S. E. co. of Texas, separated from Louisiana on the E. by the Sabine river, and bounded S. and W. by the Neches, which meets the former at Sabine lake on the S. E. corner; area, 850 sq. m.; pop. in 1858, 1,277, of whom 282 were slaves. It has a nearly level surface, about half of which is covered by a heavy growth of timber, principally pine and cypress, and a portion is wet land well adapted to the cultivation of rice. Stock is raised for the New Orleans market, and there is some trade with Galveston. Capital, Madison. VII. A S. co. of Ind., drained by Patoka and Lost rivers and Salt creek; area estimated at 400 sq. m.; pop. in 1860, 12,000. Its surface is hilly in the S. and undulating toward the N., and the soil is generally fertile. The productions in 1850 were 46,941 bushels of wheat, 484,165 of Indian corn, 96,849 of oats, 2,298 tons of hay, and 88,761 lbs. of wool. There were 14 grist mills, 2 saw mills, 5 tanneries, 25 churches, and 1,800 pupils attending public schools. Capital, Paoli.

ORANGE, PRINCIPALITY OF, formerly an independent seignior, 12 m. in length by 9 in breadth, in the S. E. of France, now included in the department of Vaucluse. Its origin is traced back to the 9th century, and it was held in succession by 4 houses: 1, that of Giraud-Adhemar, which became extinct in 1174, and a member of which, Count Raimbault (Rimbaldo), figures among the heroes of Tasso's "Jerusalem Delivered;" 2, that of Baux (1185-1373); 3, that of Ohálons, which ended in 1530 with the celebrated Philibert, one of the greatest warriors of the age; 4, that of Nassau-Dillenburg, which acquired full possession in 1570, and kept it until the death of William III., king of England, without issue (1702). Many competitors claimed the vacant estate, Frederick I. of Prussia and Prince John William Friso of Nassau-Dietz being the foremost. Each of the several pretenders assumed the title of

prince of Orange; but after a protracted contest the principality was ceded to France by the treaty of Utrecht, and has since been a part of that country. The princes of Nassau-Dietz nevertheless were allowed to style themselves princes of Orange, and since their accession to the throne of Holland that title is given to the heir apparent to the crown.

ORANGE, MAURION OF. See MAURION.

ORANGE RIVER REPUBLIC. See BOXER.

ORANGEBURG, a central district of S. C., bounded E. by the Santee, N. E. by the Congaree, and S. W. by the South Edisto, and intersected by the North Edisto; area, 1,438 sq. m.; pop. in 1850, 23,582, of whom 15,884 were slaves; white pop. in 1859, 7,812. It has a diversified surface and a soil of moderate fertility. Extensive pine forests yield large quantities of lumber and turpentine. The productions in 1850 were 10,024 bales of cotton, 614,418 bushels of corn, 189,915 of sweet potatoes, 7,299 of oats, and 1,299,879 lbs. of rice. There were 67 grist mills, 87 saw and planing mills, 66 churches, and 628 pupils attending public schools. The South Carolina railroad crosses the southern corner of the district, and the Columbia branch railroad passes through the capital, Orangeburg.

ORANGEMEN, a secret political society of the British empire, whose official designation in its own records is "The Loyal Orange Institution." It is composed exclusively of Protestants, and its professed objects are to support and defend the reigning king or queen of Great Britain, the Protestant religion, the laws of the country, the legislative union of Great Britain and Ireland, and the succession to the throne in the present royal family so long as it remains Protestant. They associate also in honor of King William III., prince of Orange, whose name they bear, "as supporters of his glorious memory." Members are admitted by ballot, and each applicant must receive at least $\frac{1}{4}$ of the votes cast. Every member must belong to a private or subordinate lodge, and can only be admitted on proof that he is a Protestant of known loyalty and over 18 years of age. Each member on admission pays an entrance fee, which in no case is less than 2s. 6d. The association is divided into five orders or degrees, the first of which is the orange, and the fifth and highest the scarlet degree. No one is eligible to the highest till he has been a member for 12 months. The officers of the lodge must be of the scarlet degree, and consist of a master, deputy master, secretary, treasurer, and 5 committee men, who hold office for one year. Meetings are commonly held once a month; the lodge is opened by prayer, after which a portion of Scripture is read, which is followed by the transaction of business, such as the balloting for candidates, admission of new members, and consideration of communications, the lodge closing with a prayer. Any member marrying a Roman Catholic must be forthwith expelled. Three or more subordinate lodges

constitute a district lodge, of which the officers are a district master, district deputy master, &c., bearing the same titles as the officers of the lower lodges with the prefix of "district." The district lodge meets 4 times in a year, and exercises a species of supervision over the lower lodges, which make regular reports to it. Next above the district lodges are the county grand lodges, whose officers, from grand master to grand committee, bear the titles already enumerated with the prefix of "grand," and are elected by the officers of the district lodges in the county. The county grand lodge meets twice a year. Finally there is in each of the three kingdoms of Great Britain and in Wales, and in the principal colonies, a grand lodge, which meets twice a year, and consists of the above mentioned "grand" officers, and of a grand committee elected by the officers of the county grand lodges. There is also an imperial grand lodge, at the head of which is the grand master of the empire, "who is its chief and supreme head. His office is permanent and uncontrolled, being confided wholly to the loyalty and integrity of that Orangeman who shall be worthy of so high a trust." The imperial grand lodge meets once a year, and is composed of the grand officers of the grand lodges of the kingdoms which compose the empire. A collateral order called the "Grand Black Order of Orangemen," or "Royal Black Knights of the Camp of Israel," exists within, but separate from, the Orange institution, to which no person is admitted who has not taken the higher degrees of the exterior society, or either of whose parents is or has been a Roman Catholic. No one can be a member who does not profess to believe in the holy Trinity. It is organized, like the Orange institution, into grand lodges, county, district, and subordinate lodges, which, however, are called chapters and preceptories, and the individual members bear the title of knights.—The Orange institution was founded in the north of Ireland in 1795, ostensibly to counteract the Roman Catholic secret associations called "the defenders" or "ribbon men." These two opposite associations were soon involved in fierce hostility with each other; and as nearly the whole peasantry of the country belonged to one or the other of the associations, all the inhabitants were in some districts arrayed under opposite banners, and were always ready for mutual conflict. Whenever the opposite factions met in any considerable numbers, insults were exchanged and riots often ensued. The law was powerless against them, because witnesses were intimidated, and jurymen sometimes refused to convict culprits belonging to their own order. In 1828 immense assemblages of the Orangemen and of the "Catholic association" were gathered tumultuously in the north of Ireland, and blood was shed in some places. In the following year the celebration by the Orangemen of the anniversary of the battle of the Boyne, July 12, led to bloody conflicts in the counties of

Clare, Armagh, and Fermanagh, in which considerable numbers were killed or wounded, and the interposition of the military with difficulty suppressed these disturbances. In 1885 a parliamentary investigation was ordered, which led to the detection of Orange lodges in 84 regiments of the army; and in the following year the imperial grand master, the duke of Cumberland, was compelled to dissolve the institution in Ireland. It was however revived in 1845, and is still extensively diffused in the British islands, though its processions are there forbidden by law. It was introduced into British America in 1829, and in 1861 it had 1,200 lodges and about 150,000 members. Its processions there are not illegal, and its political influence is very great. Much excitement was occasioned by the attempt in 1860 to compel the prince of Wales during his progress through the provinces to recognize the order and to pass under its arches and banners, a recognition steadfastly refused by the prince and his suite.

ORANG-OUTANG (*pithecus*, Geoffr., or *simia*, Linn. and Illig.), the common name of the large tailless anthropoid apes of S. E. Asia and the islands of Borneo and Sumatra. Some details have been given regarding the orangs under APE and CHIMPANZEE; and students desirous of pursuing the subject extensively are referred to the papers of Prof. Owen in the "Transactions of the Zoological Society of London" (vols. i. to iv., 1835-'56), and of Prof. Duvernoy in the *Archives du muséum d'histoire naturelle* (vol. viii., Paris, 1855). The orang usually seen in menageries is the *P. satyrus* (Geoffr.), of which the adult has been described as the *P. Wurmbiti*, the pongo of authors and the *mias* of the natives of Borneo. The pongo or adult orang is more powerful and less anthropoid than the chimpanzee (*trogodytes niger*, Geoffr.); it represents in Asia the gorilla of Africa, and varies in height from 5 to 7 feet. The forehead is contracted, sloping directly backward, with no projecting superciliary ridges; the occiput is flattened, the canines large, jaws powerful, zygomatic arches strong and expanded, and cranial ridges largely developed; the crown is less flat than in the chimpanzee; the brain cavity of the adult is very little larger than at the period of the first permanent molars, the greater size of the cranium depending on a thickening of the walls and the development of the temporal ridges; the latter commence at the external angular process of the frontal bone, and pass upward, inward, and backward to meet at the junction of the sagittal and coronal sutures, the two including a smooth triangular portion of the frontal; the interparietal crest is about $\frac{1}{4}$ inch high, as in the large carnivora, dividing at the vertex, and passing behind the lambdoidal suture to the mastoid ridge, and a rough prominence continues from the point of divarication half way down the occiput. As compared with the chimpanzee, it comes nearer man in the small portion of the wing of the sphenoid which

reaches the parietal, separating the frontal from the temporal, though this character does not hold good in all races of men nor always in the orang; the occipital foramen is further back, and its condyles are nearer together in front, with double anterior condyloid foramina; from the greater development of the canines, the incisive foramina are further back; the intermaxillary sutures are not obliterated until the permanent teeth are almost fully developed; the single nasal bone is flat, with no projection beyond the nasal processes of the upper jaw; the inter-orbital space is relatively narrower; the upper jaw has 8 infra-orbital foramina instead of one, and is larger; the incisors project more obliquely forward; there is a greater height and breadth of the rami of the lower jaw, and greater depth of symphysis. The teeth are in number the same as in man, the chimpanzee, and gorilla, the incisors and canines especially being relatively larger. The spinous processes of the cervical vertebrae are simple and very long, for the muscular attachments rendered necessary by the backward position of the occipital foramen, the great development and weight of the face, and the general anterior inclination of the vertebrae themselves; the spinal column has one general curve behind from the atlas to the beginning of the sacrum, where there is a slight curve in the opposite direction; the dorsals are 12 as in man, the chimpanzee having 18; the lumbar are 4, with shorter spines; the sacrum consists of 5 bones, and is longer, narrower, and straighter than in the chimpanzee; the coccygeal bones are 8, ankylosed together but not to the sacrum. Continuing the comparison with the chimpanzee, the ilia are more expanded and flatter, and the ischia are less extended outward, making the lower part of the pelvis narrower; the superior pelvic opening is nearly a perfect oval; the chest is ample, as large as a man's, the transverse greater than the antero-posterior diameter; the ribs are narrower and less flattened; the sternum short and wide, composed, below the first bone, of a double series of 7 or 8 small bones, always distinguishable in the young animal, but not in the chimpanzee; the clavicles very little curved; the scapulae broad and short. The principal difference is in the relative length of the upper and lower limbs; the arms reach to the heel; in the fore arm there is greater space between the bones, owing to the outward curve of the radius; the bones of the hand are elongated, those of the thumb slender and short, not reaching to the end of the metacarpal of the fore finger; proximal phalanges curved for easier prehension and climbing, and the last row not expanded for a wide sensitive bulb of a finger. The femur has no *ligamentum teres*, giving greater mobility and less solidity to the motions of the hip joint, useful in climbing, but rendering the gait on the ground awkward and shuffling; the bones of the leg are short, with greater space between them owing to the inward curve of the

tibia; the foot is turned more inward, and the os calcis does not project so far back; the phalanges much elongated, the hind thumb not reaching to the condyle of the next metatarsal, resembling a hand more than a foot. The sutures are obliterated in the adults; the large canines of these anthropoid apes bear no relation to their food, being used principally as weapons of defence against the larger carnivora, which their great strength enables them to cope with; the smaller the species and the more easily concealed, the less developed are the canines. The capacity of the adult male orang skull is 26 cubic inches, of the female 24, considerably less than in the gorilla, and about the same as in the chimpanzee; in the young, up to the age of about 5 years, the facial angle is 60°; the extremities preserve the proportions of a 6 months' human foetus, while in the chimpanzee they are those of a yearling infant. The numerous resemblances to the human structure which have served as arguments for progressive animal development have always been taken from immature specimens of these anthropoid apes, in which the facial angle, teeth, shape and relative size of cranium, assume human proportions, which are lost as the animal advances in age; the docility and gentleness of the young give place to obstinacy and ferocity in the old, as the cerebral development becomes relatively less.—The Bornean pongo has long loose hair of a deep fuscous color, approaching in some parts to black, the adult male having large dermal fatty protuberances over the cheek bones, not found in the Sumatran species; the younger specimens, both in Borneo and Sumatra, are more ruddy brown. In the immature specimens, which are the best known, the head is pear-shaped, expanding from the chin upward; the eyes close together; the external ears small; the nose confluent with the face, with nostrils but slightly elevated; mouth projecting, with large gape and very narrow lips; the abdomen protuberant; the hair on the fore arm reversed. They are fond of low marshy regions, well wooded, their whole organization being fitted for progression on trees; they seldom move far on the ground, and then on all fours or by swinging the body awkwardly forward between the arms supported by the bent knuckles; they build a kind of nest in trees, where they spend the night, leaving it late in the morning when the sun has dispersed the dew and thoroughly warmed the air; they do not live in society, except when a pair have a family in charge; the food consists of fruits, nuts, tender plants, leaves, and shoots, and is entirely vegetable in a state of nature; the natives say that they always attack and are attacked by the crocodile (*C. biporcatus*). In captivity the disposition is mild and affectionate, and the deportment grave and often melancholy; the intelligence and powers of imitation are considerable; and they get to be fond of the varied food of man, and especially his drinks, as ardent spirits and coffee. For anec-

dotes of this species see Jardine's "Naturalist's Library," vol. i., and other popular works on natural history. The Sumatran orang has been described as a distinct species, as *P. Abellii* or *bicolor* (Geoffr.); it is of large size and of a reddish brown color. A smaller and more anthropoid species in Borneo has been named *P. morio* by Owen; it is about 4 feet high, and 6½ between the ends of the outstretched arms; the ridges of the skull are rudimentary, passing from the external angle of the frontal bone, slightly converging but not meeting, and behind the coronal suture soon subsiding to the level of the skull; the canines are smaller, and are related to differences in the cranium mentioned by Owen in the "Transactions of the Zoological Society" (vols. ii. and iv., 1836-'36); it may be, according to Owen, a now permanent, though dwarfed, variety of *P. satyrus*. If the pongo represents the gorilla in Asia, the *P. morio* would parallel the chimpanzee, and the *P. Abellii* the bald nahiego recently described by Mr. Du Chaillu.

ORATORIO (Lat. *oratorium*, a small chapel), a sacred musical composition consisting of airs, recitatives, duets, trios, choruses, &c., with full orchestral accompaniment. The subject is generally taken from Scripture, and the text, which is seldom dramatic in form, is sung and recited without action or any of the adjuncts of theatrical representation. The oratorio is frequently spoken of as a species of musical drama; but many of the most noted works of the class are in no sense dramatic, the text either conveying a simple narrative, or consisting merely of detached passages of Scripture, and in a few instances being of a mixed character, as in the "Oration" of Haydn. A musical drama on a sacred subject, like the *Moss in Egitto* of Rossini, is properly an opera. The term has also been somewhat loosely applied to a class of compositions not strictly of a religious character, of which Haydn's "Seasons," founded on Thomson's poem, affords an example. The oratorio was derived from the mystery or religious tragedy of the middle ages, of which it presents a modified form, adapted to the services of the church. Its origin has generally been ascribed to St. Philip Neri, who in 1540 founded the congregation of the Oratory in Rome (whence the term oratorio), one of the objects of which was to deter young people from profane amusements by rendering religious services as attractive as possible. "For this purpose they began by the introduction of canticles, and spiritual songs and choruses; and afterward, to increase the attraction, Scripture songs and incidents were formed into dramatic poems, written in dialogue, and set to music by the best composers of the time. These productions were recited and sung, with the accompaniment of instruments, before and after the sermon; so that the attention of the congregation was thus (it was presumed) secured to the religious instructions of the preacher." (Hogarth's "Memoirs of the Opera," vol. i. p.

5.) Oratorios, in the present signification of the term, were not however produced until about the middle of the 17th century. They speedily became popular in Italy, where they were regularly performed in churches during the carnival, and gradually became a recognized form of musical composition in many parts of Europe, the subjects in Roman Catholic countries being frequently taken from the lives of the Virgin or the saints. In Germany they have been cultivated by eminent composers from Bach down to Mendelssohn and Spohr; and in England for nearly a century and a half they have proved perhaps the most popular species of music extant. In the latter country all the great works of Handel, the most eminent composer of oratorios, including "Samson," "Israel in Egypt," "Saul," "Jephtha's Daughter," and the sublime "Messiah," were originally produced. In some of the cities of the United States the taste for this kind of music has been fostered by societies of long standing and repute, like the "Handel and Haydn Society" of Boston and the "Mendelssohn Union" of New York, which perform the choice works of the composers from whom they derive their titles. In Italy oratorios are still performed exclusively in churches; but in other countries they are frequently given in public halls, concert rooms, and even in theatres.

ORATORY, the art of public speaking, including the two departments of composition and elocution, the former aiming at a peculiar style of rhetorical excellence, and the latter at a pleasing and effective action and delivery. The art culminates in eloquence. The ancient rhetoricians distinguished eloquence as either demonstrative, deliberative, or judicial. The first was designed to offer praise or blame with reference to matters of the present time, and included funeral orations, invectives, panegyrics, inaugural addresses, &c.; the second exhorts or dissuades with reference to the future, and includes moral lectures and all instructive oratory; the third relates to accusation or defence of past conduct, and includes all pleading. These different styles were often united in the same oration. Modern eloquence has been distinguished as that of the senate, the bar, the pulpit, and the platform. Luther thus mentions the "properties and virtues" requisite for a good preacher: "First, he should teach systematically; secondly, he should have a ready wit; thirdly, he should be eloquent; fourthly, he should have a good voice; fifthly, a good memory; sixthly, he should know when to make an end; seventhly, he should make sure of his doctrine; eighthly, he should venture and engage body and blood, wealth and honor in the word; ninthly, he should suffer himself to be mocked and jeered of every one." The eloquence of the ancients, and especially of the Greeks, is usually believed to have greatly excelled modern oratory. Of the 10 Attic orators approved by the Alexandrian critics, nearly all lived in the 4th century B. C. The two

greatest of these, Demosthenes and *Æschines*, were at the head of the two parties into which Attica was then divided, and were constantly opposed to each other. The former, accustomed to elaborate preparation by his early efforts to overcome natural deficiencies, never ventured to speak extemporaneously, or to trust to the impulse of the moment; and his orations are therefore models of artistic and effective arrangement. Dionysius, contrasting the effect of his speeches with that produced by Isocrates, says that the latter left the hearer in a contemplative mood, as if he had been listening to strains of the finest music, while the former inspired him with all the passions incident to humanity, and with an agitation as fierce as that which raged among the initiated during the celebration of the mystic rites of Cybele. The style of Demosthenes exhibits few attempts at philosophical reflection, few prominent ornaments, and has no pretension to wit or humor; and yet, says David Hume, "could it be copied, its success would be infallible over a modern assembly." *Æschines* excelled in improvised or extempore oratory, of which he was called the inventor. Among the Romans, Cicero and Hortensius were pre-eminent as orators, the style of the former lacking the simplicity of the Greeks, though less florid and Asiatic than that of his rival. In modern times the best examples of political oratory have been given in Great Britain and the United States. Mirabeau, Vergniaud, Lamartine, Kossuth, and other leaders in revolutionary epochs have alone rivalled the eloquence of legislative debates. Few of the speeches of the elder Pitt have been exactly reported, but enough remains to show that they have rarely been surpassed in majesty and effect. His power of extemporizing was the reward of a severe course of training at Oxford; and after entering parliament at the age of 26 he remained silent for nearly a year, carefully studying the character of the house. Throughout his public life, amid sickness and pain, he retained the passionate energy which prompted passages in his addresses that were almost irresistible. The two discussions in which his eloquence was chiefly displayed were those relating to the elections of Wilkes and to the American war. The younger Pitt was trained from childhood for his oratorical career; and while he lacked the earnestness and vivid imagination of his father, he was effective from his grasp of intellect, mastery of details, power of contemptuous sarcasm, and sonorous enunciation. The artless and vigorous speeches of Fox rank higher as specimens of oratory, though he affirmed that a speech which reads well must necessarily have been a bad one. He attributed his success as a debater to a resolution, which he formed when very young, to speak well or ill at least once every night. The failure of Burke to affect his hearers illustrates the saying of Demosthenes, that the chief excellence of oratory consists in action.

So ungraceful and frigid was his manner, and so unskillful was he in adapting his ideas to the capacities or humor of the audience, that he obtained the nickname of "the dinner bell," because his rising to speak was the signal for the audience to withdraw to dinner. Yet his speeches remain among the finest specimens of that class of literature. The speech of Sheridan in the impeachment of Warren Hastings was declared by Burke "the most splendid effort of eloquence, argument, and wit united, of which there was any record or tradition." All of Sheridan's speeches cost him excessive labor; even his jokes passed through successive editions on paper, and were subjected to long revision and condensation, and then kept in readiness for a fitting occasion. Before his greatest efforts, he was accustomed to retire into the country and give himself up entirely to study. He not only elaborated his speeches to the minutest details, but for the most part committed them accurately to memory. Erskine, who had been a midshipman and soldier, achieved sudden eminence as an advocate; but his success was the result of long continued preparation in debating clubs. Canning, the most eminent of later British orators, is remarkable for practising skillful appeals to the imagination in many beautiful and poetical pictures. His ingenuity in debating a delicate and hazardous question was displayed in his argument against parliamentary reform at the election dinner at Liverpool in 1818, in his speeches on the Catholic question, and on the projected invasion of Portugal by Spain in 1826. Lord Derby, Mr. Bright, and Mr. Gladstone are the most remarkable of living British orators.—In America, the statesmen who have been most reputed for eloquence are Patrick Henry, James Otis, Fisher Ames, Henry Clay, Daniel Webster, and Edward Everett. The interests of citizenship under a popular government have made public speaking more common and animated in America than it has been perhaps since the republics of Greece and Rome.—In the early church the most brilliant preacher was Chrysostom, who had diligently studied the Greek orators. His homilies, though sometimes displaying gorgeous imagery, were eminently practical, consisting chiefly of simple denunciations of vice and commendations of virtue. Sermons were then rarely read from manuscript, but were more frequently committed to memory. Chrysostom states that his subject was often suggested to him while on his way to the church. Clapping, shouting, and waving of kerchiefs, as tokens of applause, were then usual in churches. The finest examples of pulpit eloquence have probably been presented by the French preachers Bossuet, Bourdaloue, and Massillon. This department of oratory declined during the 18th century, but has been revived with eminent success by Lacordaire, and Ravignan. In England, Whitfield, Chalmers, and Robert Hall have been most re-

markable for power in the pulpit. Whitfield excited the highest interest not only of common people, but of court beauties and of free-thinkers like Chesterfield, Bolingbroke, and Hume. Hume said that it was worth while to walk 20 miles to hear him; and so cool and calculating a person as Dr. Franklin was prompted by one of his charity sermons, against his predetermination, to give all his coin. He is stated to have taken lessons of Garrick, and it is certain that his effect was chiefly due to his manner. His reputation would have been greater had he left no published sermons. Dr. Chalmers bestowed the severest labor upon his sermons. Eachewing all ornaments of style, preserving his broad provincial pronunciation, advancing gradually from a solemn and drawing tone, it was only when near the close that he rose to the full power of his eloquence. His power in passages is likened by those who heard him to that of a tempest; and on concluding there is said to have been invariably a deep sigh or gasp for breath audible through the entire audience. Robert Hall never delivered his sermons from manuscript, but either committed them to memory, or preached extemporaneously. His voice was weak and shrill, and he made it intense and effective by speaking rapidly. His published sermons have high literary merit.—See Maury, *Essai sur l'éloquence de la chaire* (Paris, 1810), and Hunt, "Philosophy of Voice and Speech" (London, 1859).

ORATORY, PRIESTS OF THE. See PRIESTS OF THE ORATORY.

ORBIGNY, ALONDE D', a French naturalist, born in Coueron, Loire-Inférieure, in 1802, died in Paris, June 30, 1857. He was educated at La Rochelle, and in 1824 attracted the attention of the scientific by a paper presented to the academy of sciences, in which he pointed out the existence of many creatures not previously observed. In 1826 he was sent by the government to South America, which he explored for 8 years, from Brazil and Peru to Patagonia. He collected many valuable historical MSS., 86 vocabularies of American languages, 7,000 species of animals, a large proportion of which were entirely new, and 2,500 species of plants. The results of his observations and labors were given to the public in his *Voyage dans l'Amérique du Sud* (7 vols. 4to., 1835-'52), which was printed under the auspices of the ministry of public instruction. He also published many other important works on natural history and on paleontology, to which his later years were particularly devoted, and on which he lectured in the museum of natural history from 1836 to 1853.

OROAGNA, or ORGAGNA (ANDREA DI CIONE), an Italian painter, sculptor, and architect, born in Florence in the early part of the 14th century, died in 1375 or 1389. He was the son of a Florentine sculptor and goldsmith named Cione, and is said to have acquired the surname of L'Archagnuolo (the archangel), which was con-

tracted into Orcagna. He learned design under the tuition of his father, and was instructed in painting by an elder brother, Bernardo, who was a follower of Giotto, and in concert with whom he painted a series of frescoes in the Strozzi chapel in the church of Sta. Maria Novella at Florence. His most memorable productions in this art, however, are the series on the north wall of the Campo Santo at Pisa, executed probably about 1335, representing the "Triumph of Death," "The Last Judgment," and "Hell." These works have been greatly injured by time and neglect. They were profoundly studied by succeeding painters, and Michel Angelo and Raphael borrowed largely from the attitudes and arrangements of Orcagna. As a sculptor and architect Orcagna attained, according to Vasari, even greater eminence than as a painter. One of his most celebrated productions was the tabernacle of the Virgin in the church of San Michele at Florence, a pyramidal altar of white marble ornamented with sculptured figures, one of which represents the artist himself, and is inscribed with his name and the date, 1359. The church itself was also built from his designs; but his masterpiece in architecture was the Loggia de' Lanzi in the Piazza Granduca in Florence, of which Michel Angelo declared that he could produce nothing superior.

ORCHESTRA (Gr. *ορχήστρα*), that part of the Greek theatre in which the chorus performed its dances and evolutions. It was circular in shape, except that a segment was appropriated to the stage, extended in front of the spectators, and was surrounded by steps. In modern theatres the orchestra is the space between the audience and the stage allotted to the musicians; and in concert rooms it is a raised platform occupied by both vocal and instrumental performers. Previous to the commencement of the 18th century the instrumental performers in theatres were placed in a box on the side of the stage and out of view of the greater part of the audience; but their present position, both in respect of acoustic effects and of the opportunity which it affords the singers to have in view the conductor, is considered superior.—The term is more commonly applied perhaps to a body of instrumental performers in which the violin family predominates. A body of musicians using principally wind instruments is popularly called a band. The earliest example of the composition of an orchestra is afforded by Monteverde's opera of *Orfeo*, performed in 1604, in which 20 instruments of the violin species and 12 wind instruments are employed, chiefly to accompany the voice, although they were not all played at the same time. Subsequently the stringed instruments were increased in orchestras to the almost total exclusion of other kinds, and the works of Cavalli, Carissimi, and Lully are written principally for violins, violas of different degrees of power, base viols, and double base viols. Lully sometimes employed flutes, bassoons, and trom-

bones; but it was not until after the time of Haydn's later works that the wind instruments, whether of brass or wood, began to be recognized as an important and indeed an indispensable part of the orchestra. At the present day they are used with splendid effect in military bands, and in the works of some composers encroach upon the limits of the stringed instruments, which should always be made the centre of the orchestra, and the point around which all the rest revolve. The smallest number of performers in a grand orchestra is estimated at 60, and the hall wherein they play should be of moderate size; but for the greatest effects 80 and upward must be employed. M. Fétis gives the following proportions for an orchestra and chorus of 856 performers, beside an organ of first-rate power:

Stringed.		Wind and pul-	Vocal.	
		satils.		
First violins..	30	Flutes	4	Soprano..... 50
Second do.....	30	Oboes.....	4	Alto..... 40
Violas.....	35	Clarinets....	4	Tenor..... 40
Violoncellos..	30	Bassoons....	8	Bass..... 40

ORCHIL. See **ARCHIL.**

ORCHIS, the ancient name of an endogenous, gynandrous plant, with showy flowers and tuberous roots, found in various portions of the world, but sparingly represented in the United States. It belongs to the natural order of the *orchidaceæ*, which comprises many species, all herbaceous, and distinguished by their irregular blossoms, exhibiting singular appearances and grotesque forms. The several parts of the flower of *orchidaceæ* are: 1, the perianth, of 6 divisions, the 3 outer being sepals and the 3 inner petals, of which the upper is furnished with an appendage called the lip; 2, the column, which is usually composed of a single stamen growing into and uniting with the style, and bearing a 2-celled anther; 3, the ovary, which is firmly adherent to the tube of the calyx, and is often so twisted when the flower is about to expand that its back with the floral envelopes is turned to the front; 4, the fruit, a 1-celled, 3-valved pod, filled with very fine chaffy seeds. In the orchis, the flower is ringent; the sepals and petals nearly equal, all of them, or all but the 2 lower sepals, converging upward and arching over the column; the lip turned downward, coalescing with the base of the column, and spurred at the base underneath; the anther cells 2, contiguous and parallel; the pollinia or pollen masses 2, concealed in the hood of the style. Endlicher's division of the genus is into *androrchis* and *herorchis*. Of the European species of the former we have the *orchis mascula* of Linnæus, which grows in meadows, and has oblong, undivided roots, spotted leaves, flowers many,

borne on a loose spike, sepals reflexed, lip 3-lobed, the intermediate lobe emarginate, spur blunt, horizontal; another is the spotted orchis (*O. maculata*, Linn.), with palmate roots, spotted leaves, a conical flower spike, recurved sepals, an acutely 3-lobed lip, and a slender pendulous spur. Of the latter division, *Aerorchis*, may be cited the helmet orchis (*O. morio*, Linn.), growing on dry hillsides, with globose roots, divisions of the perianth obtuse, conniving into the form of a helmet, lip large with 3 obtuse lobes, spur obtuse, cylindrical, ascending, or horizontal.—Other allied genera bear the name of orchis, of which the bee orchis (*Ophrys apifera*, Linn.) is a plant a foot high with a few large and rather distant flowers on the spike; the sepals are whitish tinged with purple, the lip velvety, brown variegated with yellow; it is a native of Great Britain, on chalky calcareous soils, and very handsome, as well as singularly curious. The fly orchis (*O. muscifera*, Linn.) is a more slender plant with purplish flowers, the sepals green, the petals narrow, the lip of a purplish brown and peculiar in shape. The spider orchis (*O. oranifera*, Linn.) has greenish flowers, with a hairy dark brown lip, covered with pale or yellowish lines. In these and similar species the shape of the lip combined with the position of the floral organs gives rise to the trivial names, which convey the appearance that each flower presents. These several kinds are not uncommon in Europe.—The showy orchis (*Orchis spectabilis*, Linn.) appears in May on the hills where there are rich woodlands, from northern New England to Kentucky; it is a conspicuous little plant, whose roots consist of thick fleshy fibres, its leaves 2, ovate, shining, its flower stem 5-angled, with a few flowers having pinkish-purple sepals and petals all arched or vaulted, and an ovate, undivided white lip. Other North American orchises are arranged under different genera established on account of some particular and diverse structure of the flower. Thus in *gymnadenia* of Robert Brown, the glands upon the stigma, which are covered in *orchis*, are bare, naked or exposed, as seen in the 3-toothed orchis (*G. tridentata*, Lindley), a small, slender-stemmed plant, with fleshy, fibrous roots, a single, oblong, obtuse leaf, spike of 6 to 12 flowers, small flowers of a yellowish color, seen in wet woods of the northern states; and in *G. flava* (Lind.), with an oblong, cylindrical spike densely covered with orange yellow flowers, appearing in July in the wet pine barrens of New Jersey, Virginia, and at the south. The genus *platanthera* of Richard is founded upon the 2 naked glands being widely separated and the anther cells diverging below. In this, of the species bearing a single leaf only, we have the dwarf orchis (*P. obtusata*, Lind.), with an obovate, obtuse leaf, a spike loosely set with 5 to 10 flowers, the upper sepal of the flower broad and rounded, the petals bluntly triangular, the lip linear, entire, bearing 2 small tubercles at

base, and the spur curved. It is to be sought for in cold peat bogs and on high mountains from Maine to New York and Lake Superior. Of the species having a 3-leaved scape may be mentioned the large, round-leaved orchis (*P. orbiculata*, Lind.), with very large, orbicular leaves, which are spread flat upon the ground, the flowers spreading, greenish white in a loose raceme. It is a conspicuous plant in rich woodlands from New England to Wisconsin, and southward along the Alleghanies. The northern white orchis (*P. dilatata*, Lind.) represents a section of these plants which have leafy stems; it bears a wand-like spike of whitish flowers with linear, lanceolate petals. It is common at the northward in cold peat bogs, blossoming in June and July. There are several other species with leafy stems, such as the yellow fringed orchis (*P. ciliaris*, Lind.), having a short spike of showy flowers of a bright orange yellow, the petals linear, fringed at the apex, the lip oblong and furnished with a very long and capillary fringe; it is common at the south, and blooms in July and August. In the peat meadows at the north is found the exquisite white fringed orchis (*P. blephariglotis*, Lind.), with pure white flowers, the petals spatulate, slightly cut or toothed at the apices, the lip oblong with the margin irregularly fringed. The ragged orchis (*P. lacera*, Gray) is common by the roadsides of E. Massachusetts, and found in other parts of New England; its stem is about a foot high, bearing oblong lanceolate leaves, and terminating in a raceme of many pale yellowish green flowers, the lip jagged or torn into a few capillary lobes. The small purple fringed orchis (*P. psychodes*, Gray) has a stem 2 feet high furnished with several oblong leaves passing into linear bracts, and ending in a large spike of purple flowers with spreading petals, the two outer of which are fringed; it is common in meadows. The large purple fringed orchis (*P. fimbriata*, Lind.) is an elegant plant, which sometimes grows upward of 2 feet high, with a thick, angular, fistulose stem, oblong-oval, obtuse leaves, an oval-oblong many-flowered spike, petals of the flowers pale purple, the 2 inner ones cut or fringed on the whole of their sides. It occurs in abundance in some portions of New England. The great purple orchis (*P. peramena*, Gray) has large, showy, violet-purple flowers, the lip paler and very ample, its divisions toothed and cut but not fringed. It is a western and southern species, and grows in moist meadows.—When cultivated, the orchis will continue for a few years in the garden, but the finer sorts require more moisture than can be readily furnished. From the roots of several European species a nutritious article of diet called salep is obtained. Such species have each two tubers charged with nutritious matter, one of which feeds the flower stem of the current year, and the other is reserved by the plant for a similar use in the succeeding year. The latter is selected for the salep; the other, being

nearly exhausted of its starch by the growth of the plant, is broken off and thrown away. After the selected tubers have been cleaned and peeled of their exterior brown skin, they are dried in an oven until they exchange their opaqueness for a semi-transparent, horn-like hue. When used, they are boiled in water or in milk to the required consistency, the result being a thick mucilaginous fluid much used as a drink by hard-working people; it is said to contain more nutriment in proportion to its bulk than any other known substance, its constituents being bassorine, gum, and starch. In Turkey and in Persia, where it is prepared from some particular species of orchis native to those countries, salep is held in high esteem; it is likewise a favorite food with pedestrian travellers in wild deserts and uninhabited regions. With this and a few other exceptions, the orchids in general are of little utility, though their beauty and graceful or singular structure are adapted to please the eye.

ORDEAL, an ancient form of trial, to determine, by a supposed reference to the judgment of God, the guilt or innocence of the accused. The word is derived from the Anglo-Saxon *ordal*, compounded, according to Spelman and Ducange, of *or*, great, and *dal*, judgment; according to Lye and Bosworth, of *or*, without, and *dal*, difference, signifying a judgment without distinction of persons. The ordeal usually went under the name of *judicium Dei* (judgment of God), or *vulgaris purgatio* (common purgation), to distinguish it from canonical purgation, in which the person cleared himself by oath. The earliest allusion we have in regard to this practice is found in the laws of Moses (Numbers v.), according to which the Hebrew woman suspected of adultery is to drink the "waters of jealousy," which if she is guilty will cause "her belly to swell and thigh to rot." There is, however, no case on record in Scripture in which this regulation was carried out. Grotius, in his commentary upon this chapter, mentions several instances of trial by water among the people of Bithynia, Sardinia, and other countries. Trial by ordeal seems certainly to have been known in Greece, as in the "Antigone" of Sophocles a sentinel who had failed in fulfilling a trust committed to his charge, is represented as declaring that he is ready to "handle hot iron and walk over fire" to prove his innocence; and this, the scholiast observes, was a usual method of purgation. In modern Europe, ordeals came early into common use, and occupy a prominent position in the history of its jurisprudence. They were of several kinds, of which the trials by fire and by water were most usual. "Fire ordeal," says Blackstone, "was performed either by taking up in the hand, unhurt, a piece of red-hot iron of one, two, or three pounds weight; or else by walking barefoot and blindfold over 9 red-hot ploughshares, laid lengthwise at unequal distances; and if the party escaped being hurt, he was adjudged

innocent; but if it happened otherwise, as without collusion it generally did, he was then condemned as guilty." The trial by fire was the one commonly in use among the higher orders, and several instances are recorded in which noble females by means of it vindicated their claims to chastity; the mother of King Edward the Confessor is said in this manner to have established her reputation when suspected of a criminal intimacy with Alwayne, bishop of Winchester, but the story wants proof.—The trial by water, the origin of which is usually ascribed to Pope Eugenius II., was confined chiefly to the lower classes, and was of two kinds, that by boiling water and that by cold water. In the former, the individual thrust into a vessel of hot water his arm, which, when withdrawn, was bound up and sealed, and at the end of 8 days examined. If no trace of scald appeared, he was declared innocent. From this practice is derived the popular expression of being in hot water. In the cold water ordeal the individual was thrown into the water, and if he floated without swimming, he was considered guilty; but if he sank, he was deemed innocent and drawn out. A trace of this practice lasted until a late period in the case of persons suspected of witchcraft, in which the unhappy victim, with the right arm bound to the left leg and the left arm to the right leg, was cast into some pond, and if the body floated the charge was thought to be proved; if, on the other hand, it had the good fortune to be drowned, the innocence of the accused was clearly established. A terrible kind of water ordeal prevailed in Malabar, where the suspected criminal was obliged to swim across a large stream abounding in crocodiles. As, according to Blackstone, both the trial by fire and the trial by water could be performed by deputy, the principal answering for the result, and the deputy only venturing on some corporeal pain for hire or for friendship, language has preserved a relic of the practice in the expression "to go through fire and water to serve one."—The corsned, or trial by the hallowed bread and cheese, was chiefly practised by ecclesiastics. A morsel of bread or of cheese, loaded with imprecations, was given the accused to eat along with the eucharist; and if the person were guilty, it was believed he could not swallow it. It is said that in this manner was choked Godwin, earl of Kent, who had been charged with the murder of the brother of Edward the Confessor. A trace of the custom survived in certain phrases of abjuration, such as: "I will take the sacrament upon it," and "May this morsel be my last." The ordeal of the cross was of two kinds. In civil suits, the two contending parties held up their arms in the form of a cross, and the one who succeeded in maintaining this wearisome position the longer was declared victorious. In criminal cases, two blocks of wood were taken, one of which was cut the figure of the cross. These were wrapped up in

wool and laid either on the altar or on the relics of some saint. An attending priest took up one of these at hazard, and if it chanced to be the one with the cross engraved upon it, the accused was pronounced innocent; but if the other, guilty. The ordeal of the bier, which lasted even into the 18th century, was common in cases of murder, and existed from a very early period. The murdered man was laid upon a bier, and the suspected criminal was obliged to touch his body, and particularly the wound. If blood flowed, if foam appeared at the mouth, or if the body moved, the charge was deemed to be proved.—The ordeal of battle (see APPEAL), from which arose the modern duel, seems to have been unknown among the ancients, except by a Spanish tribe mentioned in Livy (xxviii. cap. 21) as accustomed in this manner to settle their civil suits, when they were unable or unwilling to find any other solution. It sprang up, however, at an early period in nearly every nation of modern Europe, and is spoken of in almost every collection of the barbarian laws, except in those of the Visigoths, whose jurisprudence followed to a great extent the Roman, and those of the Anglo-Saxons, although it prevailed among the Saxons and Jutes of Germany. William the Conqueror was the first to introduce it into England. Decretals were issued against this method of deciding disputes by Pope Alexander III. in 1179 and by Innocent III. in 1216, and Louis IX. abolished it in the ordinance of 1260. From this time the practice, though sanctioned several times by sovereigns, fell gradually into disuse. There were other forms of ordeal, chiefly local, such as the weighing of witches, practised in Prussia in the 17th and in the neighboring countries in the 18th century. If they were exceedingly light, they were declared guilty. As late as 1798 some witches were weighed at Szegedin in Hungary.—The practice of these ordeals sprang from a superstitious belief that a just God would interfere to punish the guilty, and perhaps also from the very necessities of an age of violence, which required for innocence every chance for safety, however slight. With such respect were they regarded that Eadmer, the contemporary historian of the reign of William Rufus, could express in no stronger language the depth of wickedness into which that monarch had sunk, than by saying that he disbelieved in "the judgments of God." Yet, although ordeals were performed upon consecrated ground, and though so late as the reign of King John the clergy of England had the privilege of using the *judicium ferri, aquæ, et ignis*, the church early and earnestly endeavored to do away with this monstrous perversion of judicial forms. Decretals were issued against the practice. The canon law pronounced it to be the work of the devil; and the increasing use of this and of the Roman law soon caused ordeals to fall into disfavor. The temporal power, moreover, came finally to the aid of the spirit-

ual, and by the 16th century the practice with a few exceptions had been given up. According to Sir Edward Coke, it was abolished in England in the reign of Henry III. There is no doubt that there were artificial preparations for warding off the injurious effects of these trials, which, though well known to the clergy, were calculated to excite the wonder of the ignorant. Moreover, there was in the conduct of the proceedings much room for fraud, which unquestionably was liberally practised.—Ordeals were by no means confined to Europe, but seem to have been used among a large portion of the barbarous and partially civilized nations all over the globe. In Hindostan especially the system was thoroughly developed, as appears from a statement by Warren Hastings in the first volume of the "Asiatic Researches," in which the 9 following kinds of ordeal are enumerated: 1. Ordeal by the balance. In this the suspected person, after having fasted a whole day, was carefully weighed. The principal points of the accusation, written on a piece of paper, were then bound on his head, and he was again placed in the scales, where if he weighed more than before he was held to be guilty; if less, innocent; and if the same, the trial was repeated. 2. Ordeal by fire. An excavation was made in the ground 9 hands long, 2 spans broad, and one span deep, and was filled with fire of pippal wood. Upon this the accused walked barefooted, and if unhurt was adjudged to be guiltless. 3. Ordeal by water. In this the suspected criminal stood in water up to his navel, and near him a Brahmin with a staff in his hand. Three arrows being shot on the ground by a soldier, a man was despatched to bring back the furthest, and as soon as he had taken it up another was sent from the edge of the water for the remaining two. At that moment the accused, grasping the leg or staff of the Brahmin, was to dive into the water, and if he remained under until the two men returned, he was declared to be innocent. In the villages near Benares, he was obliged to remain under without raising his head until a man walked leisurely 50 paces. 4. Ordeal by poison. The supposed guilty party ate $7\frac{1}{2}$ barleycorns of poison, mixed in 192 barleycorns of clarified butter; and if the preparation produced no visible effect, he was declared to be innocent. According to another method, a hooded snake was placed in a deep earthen pot, and the accused took out with his hand a ring, seal, or coin dropped into it; if bitten, he was considered guilty; if not, innocent. 5. Ordeal by the *cisks*. In this the accused drank 3 draughts of water, in which images of the sun, of Devi, and of other deities had been washed for this purpose; and if within 14 days he became unwell, he was deemed a criminal. 6. Ordeal by rice. In case of theft, some dry rice was weighed with the sacred stone, called *salgram*, or certain *shlokas* were read over it. Of this the suspected persons were to chew a quantity, and then

throw it out upon leaves of pipperal, and if it came out of the mouth of any one dry or stained with blood, that one was held to be guilty and the rest were acquitted. 7. Ordeal by hot oil; and 8, ordeal by hot iron. These were very much the same as the hot water and hot iron ordeals of Europe. 9. The ordeal by images. In this a silver image called Dharma, the genius of justice, and a clay or iron one called Adharma, were thrown together into an earthen jar, and the accused was convicted or acquitted according as he brought out the former or the latter; or the figure of one deity was painted on white cloth, and that of the other upon black, and these were rolled up in the excrement of cows in separate balls, and cast into a vessel, after which the procedure was the same as in the previous instance.—Ordeals of various kinds, but chiefly the trials by fire and by water, are found among the Chinese, the natives of Pegu, of Congo, of the coast of Guinea, and the tribes of Asiatic Russia. In Senegambia an application of red-hot iron is made to the tongue of the supposed criminal. In Siam the accuser and the accused were placed together in one spot, and a tiger was let loose upon them. If one was spared, he was considered innocent; if both were destroyed, they were both deemed guilty; and if both were spared, they were compelled to undergo some more certain test. The missionary Krapf, in his "Travels and Researches in Eastern Africa," mentions, as in use among the Wanaka tribe, the ordeals of the hatchet, of the copper kettle, of the needle, and of the piece of bread. The first two were analogous to the hot iron ordeal and the last to the corned of Europe. In the ordeal of the needle, a red-hot needle was drawn through the lips of the alleged criminal, and if blood flowed from the wound, he was deemed guilty; but if none, innocent.—In Madagascar the trial by ordeal is still generally practised by legal authority. The supposed criminal is made to drink a decoction of a poisonous fruit called the *tangena*, a small dose of which acts as an emetic, while a large dose is fatal. By managing the size of the dose, those who administer it can decide the result.

ORDERICUS VITALIS, an English priest and chronicler, born at Attingesham, near Shrewsbury (now Atcham, Shropshire), Feb. 17, 1075, died about 1143. He early entered the monastery of St. Evroult at Ouche in Normandy, where he passed most of his life. He wrote an "Ecclesiastical History of England and Normandy," which begins with the time of Christ and concludes with the year 1141. It was first printed in Duchesne's *Historia Normannorum Scriptores* (1619), and there is a good English translation by T. Forester, forming 4 vols. of Bohn's "Antiquarian Library."

ORDERS, RELIGIOUS. See RELIGIOUS ORDERS, and MONACHISM.

ORDINARY (Roman law, *iudex ordinarius*), in its proper sense, or that which it bore in the Roman law, a judge who took cognizance of

causes in the regular course and proper right of his office, and not by way of special deputation. This acceptation of the word is very exactly preserved in the ecclesiastical law, though in books of the common law the bishop who is the ordinary in England is familiarly referred to as "one who has ordinary jurisdiction in causes ecclesiastical." The bishop of each diocese is the ordinary therein. In virtue of his office he certifies excommunications, the lawfulness of marriages, and the like ecclesiastical and spiritual matters, to the courts of common law. Formerly, and until the statute 8 Elizabeth, c. 4, under claim of the benefit of clergy, he asserted an exclusive jurisdiction over his clerks. But the particular and most prominent judicial function of the ordinary consisted in his grant of probate of wills and letters testamentary. Of these matters the bishops, or, in certain cases, the archbishops, had for many centuries, and until very recently, exclusive jurisdiction. It has been much discussed whether the probate of wills and the granting of administrations were matters entirely and originally of ecclesiastical cognizance. It is now the better opinion that they were not, but that they belonged to the county courts, or to the courts baron of the lords of manors. Certainly these courts existed and wills were made before an ecclesiastical jurisdiction was established. After that was done, and until the time of the conquest, the bishop sat with the earl in the county court. The spiritual and temporal courts were separated in the time of William I., but it is not clear to which of the two the cognizance of wills was intrusted. But Spelman asserts, mainly on the authority of Glanvil, that in the times of Henry I. and Henry II. testamentary causes were regularly heard in the ecclesiastical courts. Since that time the probate jurisdiction of all the dioceses has been in the bishops' or archbishops' courts; and from it the forms and method of probate jurisdiction were borrowed in the United States, with more or less change. Now, however, by the "probate act" of 20 and 21 Victoria (1857), and by an additional act of the next year, the whole of the probate jurisdiction of England is taken from the ordinary, and vested in a court of probate, consisting of one judge, who may also be judge of admiralty, and who exercises this jurisdiction over all parts of England. These statutes provide for the manner of its exercise, and adopt all existing usages and rules, with as little change as possible; even the subordinate officers are expressly retained by name, and their duties and official names are, for the most part, quite unaffected.—In the United States the officer to whom probate of wills is committed is called in some judge of probate, in others ordinary register, or surrogate. (See PROBATE.)

ORDINATION, the act of conferring holy orders, or of initiating a person into the ministry of religion, or setting him apart for performing ecclesiastical rites and duties. All

the Christian denominations which have a special ministry use some kind of ordination, but their opinions greatly differ respecting the authority by which it is conferred, its essence, and its effect. The Roman Catholic, the eastern (Greek, Armenian, Nestorian, and Jacobite), and the Protestant Episcopal churches agree in maintaining that ordination is a prerogative of the bishops. The Roman Catholic and the eastern churches, and the "High Church" party of the Protestant Episcopal church, deny the validity of the orders, and even the existence, of a church where there is no bishop. The Presbyterian churches, on the contrary, hold that the presbytery have authority for this purpose, and that bishops and presbyters are in Scripture the same, and not distinct orders or officers. Among the Wesleyan Methodists, the ordination of their ministry takes place in the annual conference, with a president at its head and without the imposition of hands. Among the Calvinistic Methodists, ordination is performed by the sanction and assistance of their own ministers. Among the Independents and Baptists, the power of ordination lies in the congregation, which tries the qualifications of the candidate, and gives him a call to be its minister. This call being accepted, ministerial brethren of standing assemble to examine his credentials and to inquire as to his religious and moral character and his theological views; and should all these prove satisfactory, they ordain him by prayer and laying on of hands. The society of Friends reject, together with a special ministerial office, all ceremonies of ordination for those who speak in their meetings, believing that the qualifications for the ministry of the gospel are the special gift of the great Head of the church, bestowed both upon men and women, without distinction of rank, talent, or learning, and must be received from him through the revelation of his spirit in the heart.—As to the qualifications required in a candidate for ordination, all denominations seek previously to ascertain his moral and religious character and the conformity of his theological views with those of the denomination or the particular church which he is to serve. Some churches have specified more prerequisites. In the church of England, and the other Protestant Episcopal churches which agree with it in doctrine and church government, a candidate must be 23 years of age before he can be ordained deacon, and full 24 before he can be ordained priest. He is also obliged to subscribe to the 39 articles. The council of Trent appointed that no one should be ordained save those who were provided with a benefice; and this practice still obtains in the church of England. The times of ordination are the 4 Sundays immediately following the Ember week; i. e., the 2d Sunday in Lent, Trinity Sunday, and the Sundays following the first Wednesday after Sept. 14 and Dec. 18. These are the stated times, but the bishops have the right, if circumstances make it desirable, to ordain

candidates at any time. In the Roman Catholic church the ordination for the 4 lower orders may be bestowed in exceptional cases by priests, but that for the 3 higher orders (sub-deacon, deacon, and priest) is reserved to the bishop. The Roman Catholic church makes the validity of an ordination dependent on the apostolic succession of the ordaining bishops; she rejects therefore the ordination not only of the Swedish and Danish, but also of the Anglican church, on the ground that the latter has not proved the apostolic succession of her bishops. The ordination of the Greek and the other eastern churches is not regarded as invalid, but only as illicit, as is the ordination by any bishop who is not in communion with the pope.—As to the essence of ordination, the Roman Catholic and the eastern churches regard it as one of the 7 sacraments, while in the opinion of the Protestant churches it is only a rite for setting apart a minister for his ecclesiastical duties. In the Protestant Episcopal and the Lutheran churches, the essence of the ordination has however been and is still a subject of controversy, as divines have not been wanting who have maintained the objective communication of divine power by means of the ordination. According to the Roman Catholic doctrine, ordination impresses on the ordained minister an indelible character, separating him for ever from the laity, while in the Protestant churches it only initiates him into the ministerial office. Some distinguished Protestant divines have therefore maintained, that the right of ordination should be repeated whenever a minister is called to another charge.

ORDNANCE, a term applied to all sorts of large guns used in war. (See ARTILLERY, and CANNON.)

OREADS. See NYMPHS.

OREGON, a state of the American Union, the 20th admitted under the federal constitution, bordering on the Pacific ocean, between lat. 42° and 46° N., and long. 116° 40' and 124° 25' W. Its N. boundary is the Columbia river, separating it from Washington territory, for a distance of about 800 m. from its mouth to its intersection with lat. 46° N., which it follows eastward about 70 m. to the Snake river or Lewis fork of the Columbia, and that stream is the boundary to the mouth of the Owyhee river; the line continues thence due S. to lat. 42°, and thence due W. to the ocean. Oregon is about 820 m. long from E. to W. and 280 m. wide from N. to S. Its area is about 80,000 sq. m. It contains 19 organized counties, viz.: Benton, Clackamas, Clatsop, Columbia, Coos, Curry, Douglas, Jackson, Josephine, Lane, Linn, Marion, Multnomah, Polk, Tillamook, Umpqua, Washington, Wasco, and Yamhill. All these counties save Wasco are W. of the Cascade mountains, and within 100 m. of the Pacific, the E. part of the state having very few white inhabitants, and those confined to the immediate vicinity of the Columbia river. The largest town in the state is

Portland (pop. in 1860, 2,700). It is the chief seaport, situated on the W. bank of the Willamette river, 10 m. from its mouth, which is 100 m. by the course of the Columbia from the ocean. The town site is a plain about 30 feet above the level of the river, and it is surrounded by dense forests of tall spruce, fir, and other evergreen trees. The town dates from 1847. The houses are nearly all of wood. The next town of importance is Salem, the capital (pop. 1,500), on the E. bank of the Willamette river, about 40 m. from Portland by the course of the river. It contains the state capitol and a woollen mill. Corvallis (pop. 1,000) is 20 m. further S., on the W. bank of the same river. This place was once selected by the territorial legislature to be the capital, but the federal government had appropriated money to build a capitol at Salem, and would not recognize any other. Eugene City (pop. 800) is 30 m. S. of Corvallis, also on the bank of the Willamette river. Other towns in the Willamette valley are Oregon City, Lafayette, Dayton, Santiam, and Albany. Oregon City, 9 m. S. of Portland, at the falls of the Willamette, has a great water power, and will be a manufacturing town of importance; but now the little power used is mostly spent in sawing rough lumber. On the bank of the Columbia are the towns of Astoria, Rainier, St. Helen's, and the Dalles. Astoria (pop. 400) is 9 m. from the ocean, at a point where the river is 3 or 4 m. wide. It possesses a custom house and a couple of saw mills. All the country E., S. E., and S. from Astoria is hilly, covered with dense timber, and almost uninhabited. This fact, and the fact that nearly all the import and export trade of the state is done at Portland, whither the ocean steamers run regularly, scarcely stopping at Astoria save to take on or put off a pilot, may account for the small size of Astoria, which was for a time looked upon as one of the most promising towns of the coast. St. Helen's, 10 m. below the mouth of the Willamette (pop. about 400), once aspired to be the chief port of the state, and the agents of the Pacific mail steamship company, provoked at the difficulty of ascending the Willamette to Portland in seasons of low water, established their coaling depot and office at St. Helen's; but the mercantile interest of Portland was too strong, and St. Helen's lost her trade and her hope. "The Dalles," or Dalles, so named from some rapids in the Columbia river, to which the Canadians employed by the Hudson's bay company gave that name (pop. about 1,500), is a thriving town on the S. bank of the Columbia, about 175 m. from its mouth. The town owes its importance to the rapids in the river, which at this point has a descent of 40 feet, thus interrupting the navigation and requiring goods to be transported by land for a distance of 6 or 8 m. The growth of the place must keep pace with the development of the basin of the upper Columbia, all the trade of which must go down the

river. In the valley of the Umpqua river are the towns of Winchester, Roseburg, Scottsburg, and Gardner. In the auriferous portion of the valley of Rogue river are Jacksonville (pop. 1,500) and Althouse, the two principal mining towns in the state. On the coast, about lat. 43° 20', is the village of Randolph, whose inhabitants are mainly engaged in the business of beach mining.—The population of Oregon, according to the census of 1860, was as follows:

Counties.	Whites.	Colored.	Total.
Benton	3,064	10	3,074
Clackamas	3,465	1	3,466
Clatsop	496	2	498
Columbia	583	..	583
Coos	384	..	384
Curry	393	..	393
Douglas	3,355	9	3,364
Jackson	3,694	43	3,736
Josephine	1,618	4	1,622
Lane	4,779	1	4,780
Linn	6,765	7	6,773
Marion	7,073	15	7,088
Multnomah	4,134	16	4,150
Polk	3,694	1	3,695

Umpqua	1,247	2	1,250
Wasco	1,680	9	1,689
Washington	2,801	..	2,801
Yamhill	3,244	1	3,245
Total	52,343	121	52,464

There are about 2,000 Chinamen, of whom the great majority are working in the gold placers. There is no accurate report of the number of Indians, but they are estimated at 10,000. The Rogue river, the Coos, the Ohetco, the Umpqua, the Tillamook, the Klamath, and the Chinook tribes, though numerous 15 years ago, have now been reduced to a few scattered representatives. East of the Cascade mountains are a few Cayuses, Pah-Utes, and Snakes.—The principal rivers of Oregon are the Columbia and Snake rivers, which do not at any point come within its limits, but only form part of its northern boundary; the Willamette, Fall river (which drains a large and desolate region E. of the Cascade mountains), the John Day's, Umatilla, Grande Ronde, Powder, Burnt, Malheur, and Owyhee rivers, all tributaries of the Columbia and Snake rivers; and the Rogue and Umpqua rivers, large streams which fall into the ocean between lat. 43° and 44° N. Smaller streams emptying into the Pacific are the Coos, Coquille, Siusclair, and Tillamook rivers. The Columbia is navigable 96 m. from its mouth for vessels drawing 16 feet of water. The river where it opens to the sea is 4 m. wide, and that width continues for 18 m. inland. Off the mouth is a bar with 18 feet of water at low tide. The channel is narrow and crooked, the bar is difficult, the winds are frequently high, and fogs common; and the entrance is considered dangerous by mariners and insurance companies. Inside, the navigation is excellent, the river being wide and the water deep. At the Cascades, 183 m. from the ocean, the Columbia falls 40 feet in 5 m., interrupting navigation; and 60 m. further up there is another similar interruption by a

fall of 40 feet at the Dalles. The Willamette is navigable for vessels drawing 12 feet from its mouth to Portland; thence to the falls at Oregon City for vessels drawing 6 feet; thence to Salem for vessels drawing 4 feet; and from Salem light steamers can run to Eugene City during a portion of the year. The Columbia, though not straight, has no short turns, whereas the Willamette, meandering through a flat valley, has a multitude of small crooks, with numerous sloughs and arms. Snake river is probably navigable, but no steamers have been placed upon it. The ports of Oregon, beside those on the Columbia river, are Port Orford, Coose bay, Umpqua river, and Tillamook bay. Port Orford, in lat. $42^{\circ} 25'$, is safe during the summer, that is, while the N. winds blow, but is open to the S. and is insecure during the winter months. The harbor is deep and of good size, and has a good anchorage. Coose bay, in lat. $43^{\circ} 30'$, has an entrance about $\frac{1}{2}$ of a mile wide, with 10 feet of water on the bar at low tide. Inside, the water is deep and the anchorage perfectly secure. Port Orford and Coose bay rarely have any vessels at anchor in their waters. The Umpqua river, in lat. $43^{\circ} 45'$, has an entrance about $\frac{1}{2}$ m. wide, and 15 feet water at low tide. Inside, the water is deeper and the anchorage safe. This and Portland are the only two ports of Oregon regularly visited by ocean steamers. In lat. $45^{\circ} 45'$ is False Tillamook bay, which is nearly round, $\frac{1}{2}$ m. in diameter, with an entrance $\frac{1}{2}$ m. wide, opening to the S. The harbor is secure against all winds save those from the S. There are no islands off the coast of Oregon. The principal lakes are the Upper Klamath lake, the Lower Klamath lake, part of which is in California, and several smaller lakes or sinks of rivers in that portion of the great basin lying within the limits of Oregon. All these lakes are in districts where the soil is poor and the vegetation scanty.—There are two principal mountain ranges in Oregon, both running N. and S., the Coast and the Cascade chains. The Coast mountains, lying along the coast from lat. 42° to the Columbia, vary from 2,000 to 4,000 feet high; they are covered with evergreen trees. The Cascade mountains, forming a portion of the high range running from lat. 55° to 35° , and known as the Sierra Nevada in California, are from 4,000 to 10,000 feet high, with occasional peaks rising still higher. This range on its W. slope is covered with coniferous trees; much of its E. slope is bare. The principal peaks are Mt. Hood, in lat. $45^{\circ} 20'$, 13,000 feet high; Mt. Jefferson, in lat. $44^{\circ} 40'$, 11,000 feet; the Three Sisters, in lat. $44^{\circ} 10'$, 11,000 feet; and Mt. Pitt, in lat. $43^{\circ} 25'$, 10,000 feet. All these rise into the region of perpetual snow, and all of them are extinct volcanoes. How long they have been extinct is not known, but the Indians have traditions of a time when Mt. Hood was an active volcano. Other mountain ranges are the Blue ridge, W. of the Owyhee river; the Siskiyou ridge, between

Oregon and California; the Umpqua mountains, between the Umpqua and Rogue rivers; and the Calapooya mountains, between the valleys of the Umpqua and Willamette rivers.—Nearly all the tillable land in the state is in the valley of the Willamette, a body of land about 120 m. long from N. to S. by 30 m. wide. The soil is a gravelly clay near the mountains, covered with a rich sandy loam along the banks of the streams. In the valleys of the Umpqua and Rogue rivers, about 40 m. from the ocean, there are tracts of similar soil, each about 40 m. long by 20 wide, speaking in general terms. These rivers, when approaching the Pacific, run through steep mountains covered with timber so dense that cultivation is not now thought of. The low land along the banks of the Columbia is so narrow that it scarcely deserves to be taken into consideration in an examination of the agricultural district of Oregon. Fall river has a large basin, but the most of the soil is rocky and desert-like, the elevation high above the sea, the climate dry and cold. There is some good soil in the valleys of the Umatilla, Grande Ronde river, and Burnt river. South of the valley of Fall river lies part of the great basin, which sends no water to the sea, but swallows up all its own streams. Several such streams sink into the sands within the limits of Oregon. The soil is barren and verdureless.—The geological character of Oregon is marked by the predominance of tertiary sandstone in the west, granite in the Cascade mountains, and trap and other eruptive rocks in the E. part of the state. The valley of the Willamette has a deep diluvium strongly resembling that on the shores of Puget sound and in the Sacramento basin, and the resemblance suggests the idea that these valleys are of the same origin and were once connected together, though now separated by the Siskiyou, Umpqua, Calapooya, and Cowliiz mountains. In the Cascade mountains, beside the granite, are found trap, serpentine, porphyry, slate, quartz, and lava, the latter evidently poured out by the great volcanoes which now stand as silent snow peaks. Gold has been found in quantities sufficient to reward miners for their work in the valley of Rogue river and on the ocean beach from the S. boundary to near the Umpqua river. It has also been found in many other places E. and W. of the Cascade mountains, but not in diggings that would pay. It is rumored that valuable silver mines have been discovered in the valley of the Santiam. Copper has been found in the Calapooya mountains, and iron in the Coast mountains near Portland; platinum, iridium, and osmium are found in considerable quantities in the gold placers of southern Oregon; and large beds of tertiary coal lie on the shores of Coose bay.—Western Oregon has a moist, equable climate; eastern Oregon, one dry and variable. In the Willamette valley there are no great extremes of heat and cold. The average temperature of the spring is 54°

F., of the summer 70°, of the autumn 54°, and of the winter 40°. The amount of rain is very great; the sun is often hidden for more than a month at a time. Drizzling rains and thick mists prevail during a large portion of the year. Thunder, lightning, hail, and snow are rare. Ice seldom forms more than a couple of inches in thickness, and soon thaws. The heat of summer is never oppressive. At Astoria the fall of rain is still greater, measuring 86 inches annually, more than in any other place in the American Union. The Cascade mountains cut off the eastern division of the state from the coast winds, fogs, and rains, and this, in conjunction with the high elevation, renders that part of the country hot in summer and very cold in winter, the thermometer in July ranging as high as 80°, and in the winter falling below 20°.—The eastern part of Oregon is very poor in vegetation, the western very rich. In the valleys of the Fall and Snake rivers, a man may travel for days without passing a tree; in the valleys of the Willamette, Umpqua, and Rogue rivers he is never out of sight of dense forests. Nearly all the trees are coniferous evergreens. Among these, the most prominent are the Douglas spruce or red fir (*abies Douglasii*), the yellow fir (*A. grandis*), Williamson's spruce (*A. Williamsonii*), the Oregon cedar (*Thuja gigantea*), the noble fir (*picea nobilis*), the western balsam fir (*P. grandis*), the sugar pine (*pinus Lambertiana*), the western yellow pine (*P. contorta*), and the fragrant white cedar (*cupressus fragrans*). These are all trees of magnificent size and beautiful form, standing in dense forests, and some of them rising to a height of 250 and even 300 feet, with trunks from 4 to 10 feet in diameter. Less striking and important are the western yew (*taxus brevifolia*), the western juniper (*Juniperus occidentalis*), the Oregon oak (*quercus Garreyana*), the Oregon alder (*alnus Oregona*), and the Oregon ash (*fraxinus Oregona*). The forests of Oregon are filled with a dense and tangled undergrowth, in which ferns and bushes bearing berries and thorns are numerous. The greater part of the level land of the Willamette valley and part of the Umpqua and Rogue river valleys are prairie land; that is, they are not covered with trees. East of the Cascades the vegetation is not only far more scanty, but it is entirely different in character. The trees are scattered, stunted, and twisted, the grass is thin, and almost the only bush is the wild sage or *artemisia*, one of the most cheerless and worthless of all plants.—The principal indigenous quadrupeds of Oregon are the grizzly bear, black bear, American panther (*felis concolor*), the wild cat, the gray wolf, the coyote (*canis latrans*), the mountain sheep, the elk, the black-tailed deer, and the antelope. The most prominent birds are the Californian vulture (*cathartes Californianus*), the turkey buzzard, the golden eagle, the bald eagle, the fish hawk, the trumpeter swan (*cygnus buccinator*), the American swan, the Canada goose, the

snow goose, the brant, 4 species of albatross, 3 of pelicans, and 7 of gulls. Of reptiles there are none deserving special mention, save the rattlesnake, which is not abundant. The rivers of Oregon abound in salmon at the proper seasons; there are about a dozen different varieties, and all of them when they first enter the fresh water from the ocean are delicious. Most of the animals and vegetables found in Oregon are indigenous to that coast, and are not found elsewhere. This remark extends to the fish and the birds as well as to the quadrupeds and the trees.—The most remarkable natural curiosities of Oregon are the rapids of the Columbia river at the Cascades and the Dalles, the falls of the Willamette at Oregon City, the high snow peaks of the Cascade range, the glaciers of Mts. Hood and Jefferson, large beds of lava on the slopes of the Cascade mountains in various places, numerous hot springs along the E. base of the Cascade mountains, and the sinking rivers of the great basin.—Agriculture is the chief occupation of the people. The main agricultural products are wheat, oats, potatoes, and apples. The climate is too moist and cool for maize, peaches, melons, and sweet potatoes. A great obstacle in the way of the farmer in Oregon is the fern, which grows in nearly all fields. There is one woollen mill at Salem, the only large manufacturing establishment in the state. There are saw mills to saw all the timber required for home consumption, and grist mills to grind all the grain.—Oregon has little foreign commerce, and that little is nearly all done by steamers with San Francisco and Victoria, British Columbia. Some goods are sent to British Columbia by land up the valley of the Columbia river. The chief exports of domestic produce are wheat, flour, apples, cattle, pickled salmon, eggs, butter, and chickens. The entrance of the Columbia river is so dangerous for sailing vessels, and the price of coal is so high on this coast, that freight to and from Oregon must always be expensive. Two of the most notable roads in the state are the stage road from Portland S. to Yreka in California, and the road across the Cascade mountains from Portland to the Dalles.—Oregon has no railroad or canal. There is no federal fortification, arsenal, navy yard, or hospital in the state. There are small military stations occupied by federal troops at the Dalles, Yamhill, and in Rogue river and Umpqua valleys. The state has few public institutions. The difficulty and expense of getting agricultural produce to market, the Indian war of 1855, and the refusal of the federal government to pay the war debt, have had a strong influence to prevent the growth of the state in population and wealth, and to delay the establishment of prominent public institutions. There are 2 colleges, 7 academies, and about 300 common schools. There is a common school fund consisting of the proceeds of lands granted to the state for that purpose, all escheats, forfeitures, moneys paid as exemption from military duty, all gifts

and devises for common school purposes, the proceeds of the 500,000 acre grant, the 5 per cent. net proceeds of the sales of public lands, &c., the interest of the fund to be divided among the counties in shares proportioned to the number of children in each between 4 and 20 years of age. The governor, secretary of state, and state treasurer compose the board of school commissioners. There was in the treasury, Sept. 10, 1860, to the credit of the common school fund, the sum of \$11,584, beside a university fund of \$5,794. The leading religious denominations are the Methodist church North, the Methodist church South, and the Baptist, which have churches in nearly every town. The Roman Catholics, Presbyterians, and Episcopalians have also some churches. Two daily newspapers and half a dozen weeklies are published in Portland; and Oregon City, the Dalles, Salem, Corvallis, Eugene City, and Jacksonville have each one weekly newspaper.—The government of Oregon is exercised by a governor (salary \$1,500), a secretary of state (\$1,500), and treasurer of state (\$800), who are chosen by a plurality of votes for 4 years. During the first 5 years under the constitution of 1857 the governor is *ex officio* superintendent of public instruction; after 1862 a separate superintendent may be elected. The secretary of state is *ex officio* auditor of public accounts. The governor, secretary of state, and treasurer are eligible for reelection for any number of terms, though not for more than two successively. A state printer is chosen by popular vote for 4 years. The legislature is composed of two branches, a senate of 16 members and a house of 34 representatives. Senators are chosen in single districts for 4 years, one half every second year, and representatives for 2 years. Their numbers may be increased, but are never to exceed 30 senators and 60 representatives. Members of each house receive \$3 a day and \$8 for every 20 miles of travel, but it is provided that the *per diem* of no member shall exceed \$120. The sessions are biennial. Extra sessions may be called for any period not exceeding 20 days. The judiciary comprises a chief justice and 3 associate justices of the supreme court (salary \$3,000 each), who are chosen in districts for 6 years, the oldest or the one having the shortest time to serve being chief justice; their number may be increased, provided it do not exceed 5 until the white population of the state is over 100,000, and never exceed 7. The supreme court is only a tribunal of appeals. Each justice holds a circuit court with both original and appellate jurisdiction, the terms being so arranged that a court shall sit twice a year in each county. Whenever the population of the state exceeds 500,000, the legislature is empowered to provide for the election of supreme and circuit judges in distinct classes. Inferior judges, who also act as judges of probate and county commissioners, are chosen in each

county for 4 years. Sheriffs and clerks of courts are elected in every county, and district attorneys by districts. The revenue of the state for the year ending Sept. 10, 1860, including a balance of \$4,556.26 remaining from the previous year, was \$72,122.12, and the expenditure for the same period was \$71,062.16, leaving a balance of \$1,059.96. There is no public debt, and the state has no power to lend its credit or contract obligations to a greater amount than \$50,000, except to repel invasion or for certain other specified objects. No county shall incur any debt over \$5,000, with the like exceptions. No bank or moneyed institution shall be incorporated, nor shall any such exist with power to circulate paper money. Corporations may be formed under general laws, but shall not be created by special acts, and the stockholders shall be individually liable to the amount of their stock subscribed and unpaid, and no more. The amount of taxable property in 1858 was \$22,824,118, and in 1859 \$24,181,669; amount of state tax in 1858, \$23,754; in 1859, \$49,863. Estimated expenditures for the next two years, \$61,700.—The name of Oregon was long applied to all the territory claimed by the United States on the Pacific coast, extending from lat. 42° to 54° 40' N. In 1846, by treaty with Great Britain, the United States abandoned all claim to the country N. of lat. 49°, and the name of Oregon was by so much restricted. In 1853 the name was further restricted to the land S. of the Columbia river and lat. 46°, by the act creating the territory of Washington N. of that line. In 1859 Oregon suffered another reduction, nearly one third of its extent as a territory having been cut off from its E. end when it was admitted into the Union as a state, when the district between the Owyhee river and the Rocky mountains was added to Washington territory.—The coast of Oregon was seen by various navigators in the 17th and 18th centuries; but its history as known to civilized man may be said to commence with the discovery of the Columbia river by Capt. Robert Gray, who entered its mouth in the American ship Columbia from Boston, May 7, 1792, and gave the name of his vessel to the river. On his return to the United States he made so favorable a report of the majestic river of the west, that statesmen became desirous to secure it and its valley for the Union. This desire led the administration of Jefferson to send an exploring expedition under the command of Captains Lewis and Clark across the continent in 1804 and 1805. The expedition was successful, and while it collected much valuable information about extensive districts previously almost unknown to civilized man, it gave the Americans an additional title to the country. In 1808 the Missouri fur company sent trappers and traders to Oregon. In 1811 the American fur company, of which John Jacob Astor was the leading member, established a trading post at

the mouth of the Columbia river, and called it Astoria; but it was very soon sold to the north-west fur company to save it from being taken during the war. The north-west and the Hudson's bay company, both British associations, for a while separate and afterward united, engaged in trapping and trading, kept many trappers and traders in Oregon until within a very brief period, for it was only in 1860 that their trading post at Fort Vancouver on the Columbia, nearly opposite the mouth of the Willamette, was abandoned. The Hudson's bay company employed many Canadians among its trappers, and these formed for a long time the main body of the white population. Most of them took Indian wives and were the fathers of numerous half-breed children. Great Britain claimed all of Oregon until 1846, when the boundary treaty was made with the United States. In 1839 the emigration of Americans commenced overland by way of the South pass, and there were a few emigrants every year until 1845, when several hundred went, and the next year there were several thousand; in 1847 and 1848 there were a few hundred, and in 1849 perhaps 1,000 again. In 1848, '49, and '50, however, Oregon lost many of her citizens by the gold excitement in California; but in the last named year she gained again from California in consequence of the passage of the "donation law" by congress, giving without cost 320 acres of public land to every person settled on such land before Dec. 1 of that year, and 320 acres more to his wife; and to those persons who should settle between Dec. 1, 1850, and Dec. 1, 1853, 160 acres to each man and 160 to his wife. Under this law 8,000 claims were registered in Oregon. It was a condition of these grants that the settler should reside on the land for 4 years. The donation induced nearly all the inhabitants of Oregon to remain, and led many of the young men to marry. As the men much exceeded the women in number, girls even as young as 14 years were in great demand; and for several years after the "donation law" went into effect the territory had a wonderfully large proportion of very juvenile wives and mothers. Oregon was formally organized as a territory on Aug. 14, 1848, previous to which time there had been a provisional government with the capital at Oregon City. On March 2, 1853, the territory of Washington was established out of the northern half of Oregon. In the summer of 1857 a constitutional convention was held, and drafted a state constitution, which was submitted to popular vote on Nov. 9, 1857. With the constitution were submitted the questions whether slavery should be legalized in the state, and whether free negroes should be permitted to reside in it. The result was favorable to the constitution, and against slavery and free negroes. On Feb. 14, 1859, the state was admitted by act of congress under the constitution adopted in 1857. Oregon has been

troubled with many Indian wars. From 1845, when the disturbances began, until the present time, there has always been a hostile feeling between the whites and the red men. This hostility most of the time did not amount to an open warfare, but simply led to the shooting down of a man or two occasionally. A state of affairs very similar to this still continues in the eastern part of Oregon. Neither red nor white man is safe alone while persons of the other color are near. In 1855 the hostility broke out into a general war, which lasted more than a year, and led to a multitude of skirmishes and many deaths, but no serious battle was fought. In 1858 there was another war, but it was confined to the eastern portion of Oregon and Washington, and little damage was done by it to the industry, trade, or white population of either territory. The gold mines of the Rogue river valley in southern Oregon were discovered in 1851, but were not much worked previous to 1858.

OREGON, a S. co. of Mo. bordering on Ark., drained by Eleven Points and Spring rivers, tributaries of the Big Black river; area, about 1,650 sq. m.; pop. in 1856, 8,405, of whom 19 were slaves. It has an undulating surface and fertile soil. The productions in 1850 were 69,201 bushels of Indian corn, 3,257 of wheat, 5,512 of oats, and 2,019 lbs. of wool. There were 2 saw mills, 1 tannery, 4 churches, and 86 pupils attending public schools. Capital, Thomasville.

OREGON RIVER. See COLUMBIA RIVER.

OREL, ORIEL, ORELI, or ORLIK, a river of Russia, tributary to the Dnieper. It rises in the S. part of the government of Kharkov near Efremovakala, flows S. W., forms part of the frontier of the government of Ekaterinoslav, separating it from that of Pultowa, passes Alexopol, and finally joins the Dnieper on its left bank after a total course of about 185 m., 35 m. W. N. W. from Ekaterinoslav. Its waters are sluggish and muddy.

OREL, a central government of European Russia, bounded by the governments of Kalooza, Toola, Tambov, Voronej, Koorsak, Tchernigov, and Smolensk; area, 18,253 sq. m.; pop. in 1856, 1,445,900. The principal rivers are the Desna, a tributary of the Dnieper; the Oka, which rises in the N. portion of Orel, and runs through the centre of the government toward the Volga; and the Sorna in the E., which flows to the Don. Limestone, sandstone, and alabaster are abundant, and iron ore is found. The climate is mild and healthy; grain, hemp, flax, and tobacco are raised. The extent of arable land is estimated at 2,599,206 acres, and about $\frac{1}{4}$ of the surface is covered with forests. Beet root sugar and coarse linen and woollen cloths are manufactured.—ORELI, the capital, is situated at the junction of the Oka and Orel, 201 m. S. S. W. from Moscow; pop. in 1851, 25,630. It has direct water communication with the Baltic, Black, and Caspian seas, and carries on a large trade with all the countries

bordering on those seas, and also with St. Petersburg and Moscow.

ORELLANA, FRANCISCO, a Spanish adventurer, born in Truxillo about the beginning of the 16th century, died on a voyage across the Atlantic in 1549. He accompanied Francisco Pizarro to Peru in 1581, and took part in the conquest of that country by the Spaniards. When in 1540 Gonzalo Pizarro set out to explore the regions east of the Andes, Orellana was second in command of the expedition, which comprised 850 Spaniards, 4,000 Indians, and 1,000 dogs for hunting down the natives. After a tedious and perilous march across the Andes the army discovered the Napo, one of the upper affluents of the Amazon. Pizarro, despairing of returning by the route he had traversed, spent two months in constructing a brigantine large enough to hold the weaker part of his company and his baggage, and gave the command of the vessel to Orellana, with instructions to keep alongside of the army while it followed by land the course of the unknown stream. After several weeks passed in the descent through a dreary wilderness, their provisions were entirely exhausted, and Pizarro, hearing of a populous and rich district at the distance of several days' journey down the river at the point where the Napo flowed into a still greater stream, despatched Orellana and 50 soldiers in the brigantine with orders to proceed to the confluence of the waters, procure a supply of provisions, and return to the relief of the starving army. Borne swiftly down the current of the Napo, the brigantine in 8 days reached the Amazon, then for the first time navigated by a European vessel. Orellana found the country a wilderness, and altogether unlike what had been represented; so far from being able to procure supplies for the army, he could barely obtain sustenance for his own party. To return against the current was difficult if not impossible, and in this dilemma he resolved to embark at once on the great river before him and follow its course to the sea. His comrades were easily persuaded to this enterprise, and Orellana apparently with little hesitation abandoned his commander and set out on his voyage, which he boldly prosecuted for 7 months amid almost incredible dangers and privations. Many times his vessel was nearly dashed to pieces in the rapids of the river, and he was in still greater peril from the warlike tribes on its borders, who attacked him whenever he attempted to land, and often pursued him for miles in their canoes. He reached the ocean in Aug. 1541, and sailed to the island of Cubagua, and thence to Spain, where he excited great wonder and admiration by relating that he had passed through a country inhabited only by women who were warriors and conquerors, and that he had received authentic information of the existence of an El Dorado where gold was so plentiful that houses were roofed with it. He obtained from the Spanish crown a commission to conquer and

colonize the region he had discovered, and after some years he organized an expedition for the purpose, but died on his voyage to the mouth of the Amazon. That river is supposed to have received its name from his tale of the Amazons on its banks, and has sometimes been called from him the Orellana.

ORENBURG, a government of Russia, situated partly in Europe and partly in Asia, bounded by Perm, Tobolsk, the Kirghis steppes, the Caspian sea, Astrakhan, Saratov, Simbirsk, Kasan, and Viatka; area, 146,986 sq. m.; pop. in 1856, including the Cossacks of the Ural, 1,919,590. The province is of very irregular shape, and the chain of the Ural mountains traverses it from N. to S. The surface is greatly diversified. In the S. it is a steppe, but on the European side of the mountains it is undulating, varied, and picturesque; while toward the N. on the Asiatic side there is an extensive plain, with numerous swamps and small lakes. The drainage of the E. part of the province flows toward the Arctic ocean by the Tobol, Abuga, Ooi, and Miyas; and that of the W. portion to the Caspian sea through the Bielaya, Samara, and other tributaries of the Volga, and the Or, Sakmara, and Ilek, flowing into the Ural, which here forms the boundary between Europe and Asia. The range of the thermometer is very great, the heat in summer being excessive, while in winter the cold is intense. Gold, copper, iron, and salt are mined. A very extensive trade is carried on with the tribes of the Kirghis and the people of Bokhara, in metals, grain, horses, cattle, sheep, leather, furs, tallow, salt, and fish. The inhabitants are chiefly Russians, but there are considerable numbers of Tartars. There are several district schools in the government of Orenburg, and a young ladies' seminary was established in 1859 by voluntary contribution in its capital, Ufa.—ORENBURG, a town of the above government, on the river Ural, 465 m. N. E. from Astrakhan; pop. about 16,000. The streets are broad but badly paved, and the houses are principally constructed of wood. There are several churches, 2 mosques, and an agricultural and a military school. The manufactures are chiefly coarse woollen cloth and leather. Upon the left bank of the Ural, about 2 m. from Orenburg, there is a caravansary where the annual caravans from Bokhara and Khiva stop, and where different productions of S. E. Asia are exchanged for cattle and the produce of the surrounding country. In the neighborhood there are extensive tallow-boiling establishments. The extension of Russian territory into the interior of Asia, consequent upon the voluntary submission of several Kirghis tribes in 1781, led to the foundation of this city, which became the centre of the administration of the new territory. It is now the chief military station on the frontier, and the focus of the Russian trade with central Asia.

ORESTES, a Greek legendary hero, son of Agamemnon and Clytemnestra, and brother

of Clysothemis, Electra, and Iphigenia. He is represented as the avenger of his father, and the deliverer of his sister, through the murder of his mother. He was the theme of the tragic poets, who enlarged and embellished the simple Homeric narrative. Thus they said that at the time of the murder of Agamemnon it was intended to despatch Orestes, but his sister Electra saved him, and intrusted him to a slave, who carried the boy to Strophius, king in Phocis. In his house Orestes lived, together with Pylades, the king's son, and between the youths there sprang up a friendship which has become proverbial. Being frequently importuned by his sister Electra, and instructed by the Delphian oracle, to avenge his father's death, he repaired in secret to Argos, pretending that he brought the tidings of Orestes' death, at which Clytemnestra was overjoyed. With the complicity of Electra, he killed Clytemnestra and her paramour Ægisthus, but immediately afterward became mad, and was driven by the Furies from land to land, until by the advice of Apollo he took refuge with Minerva in Athens. The goddess commanded that his case should be decided by the court of the areopagus; and when they were equally divided, she pronounced him innocent. According to another legend, Apollo directed him to go to Tauris in Scythia, and bring to Athens the statue of Diana which had fallen from heaven. Orestes and Pylades sailed for Tauris, and on their arrival were seized by the natives in order to be sacrificed to Diana, according to the custom of the country. But the priestess of Diana was Iphigenia, Orestes' sister, and on their mutual recognition all three escaped with the statue of the goddess. The Furies were now appeased. Orestes ruled over his father's kingdom at Mycenæ, afterward became king of Argos, and married Hermione, the daughter of Menelaus. He died of the bite of a snake in Arcadia, and was buried in Sparta. According to another legend he was buried in Aricia, whence his bones were afterward carried to Rome. The history of Orestes is the subject of several celebrated dramas by Æschylus, Sophocles, and Euripides.

OREUS. See HISTIA.

ORFILA, MATEO JOSÉ BONAVENTURA, a French physician, of Spanish parentage, the founder of the science of toxicology, born in Port Mahon, Minorca, April 24, 1787, died in Paris, March 12, 1853. His father was a merchant in rather moderate circumstances; and designing his son for the same pursuit, he sent him on a trading expedition to Sicily and the coast of Africa. Young Orfila, however, manifested so strong a predilection for the study of medicine, that his father sent him successively to Valencia and Barcelona, where he so much distinguished himself that the junta of Barcelona resolved to defray the cost of his further education in Paris, on condition that he should return to Barcelona as a professor in their medical school. He arrived in Paris, July 11, 1807.

Young, handsome, and genial in his disposition, he made many friends and gained general good will. The outbreak of the Spanish war soon deprived him of his pension, and rendered him liable to be expelled from France; but an uncle at Marseilles supplied him with the necessary funds; and Vauquelin, the chemist, claiming him as his pupil, obtained permission for him to stay in Paris unmolested. At the end of 4 years (Oct. 27, 1811) he was graduated, and immediately became a private lecturer on chemistry in the French capital, where large audiences crowded around him. The first edition of his great work, *Traité des poisons, ou toxicologie générale*, appeared in 1813, and attracted considerable attention. On the establishment of peace in 1814, he signified his readiness to fulfil his part of the agreement made with the authorities of Barcelona; but the city declined the offer, as it could not afford to pay his salary. He now made application to become a French citizen, married (July, 1815) Mlle. Gabrielle Lesueur, daughter of a sculptor of some repute, and was elected corresponding member of the academy of sciences. On the occasion of a short visit to Minorca in the beginning of 1816, he was received with great honors. On his return to Paris, he was nominated, through the influence of Decazes, a physician to Louis XVIII. In 1819, having received his first letters of naturalization, he was appointed professor of medical jurisprudence in the faculty of medicine; in 1823 he succeeded Vauquelin as professor of chemistry; and in 1831, on the resignation of Antoine Dubois, he was made dean of that faculty, an office of both honor and responsibility. He was now in the full tide of prosperity; his public lectures were as popular as ever; his works ranked as masterpieces; his drawing room was the rendezvous of the choicest society, and admission to his musical evening parties was eagerly sought for. He was scarcely less accomplished as a singer than as a man of science. In 1832 he was chosen a member of the general council of hospitals in Paris; subsequently a member of the general council of the department of the Seine; and in 1834 one of the council of public instruction. He now received his letters of full naturalization, and had hopes of being promoted to a peerage, in which, however, he was disappointed. His authority as a scientific man had also reached its zenith; as a toxicologist he was without a rival, and the evidence which he was called upon to give on numerous murder trials, especially on that of Mme. Lafarge, and in 1850 on that of the count of Bocardé, for poisoning, served greatly to increase his reputation. In his official capacity he also effected several important improvements, which materially enhanced the progress of medical students by new facilities being afforded for demonstration and study; he organized the clinical hospital, established a new botanical garden, the museum of pathological anatomy styled *musée Dupuytren*, founded under

the will of that illustrious surgeon, and a gallery of comparative anatomy, to which his own name has been given. Under his administration, the service in the public hospitals was rendered more efficient, while the range of studies in the various schools of medicine was improved or elevated and enlarged. He was the founder of a provident association (*société de prévoyance*) among the physicians of Paris, of which he was elected the first president. On the revolution of 1848 he lost all his distinctions, except his professorship. In 1851 he was elected president of the academy of medicine, and in his will he left to that society and to 6 other public institutions the sum of 121,000 francs to establish prizes and for other useful purposes. Perhaps the most original of his works, and that upon which his fame mainly rests, is his *Traité de toxicologie*, which was successively enlarged and improved until the 5th edition, which appeared in 1852, in 2 vols. 8vo. Of this, an English physician says: "It is a vast mine of experimental observation on the symptoms of poisoning of all kinds, on the appearances which poisons leave in the dead body, on their physiological action, and on the means of detecting them. . . . Few branches of science so important in their bearings on every day life, and so difficult of investigation, can be said to have been created and raised at once to a state of high advancement by the labors of a single man." His other publications, which are also considered standard works in their line, are *Éléments de chimie appliquée à la médecine* (1817; 8th ed., 2 vols. 8vo., 1851); and *Traité des exhumations juridiques* (2 vols. 8vo., 1881), which was afterward merged into the *Traité de médecine légale* (1823-'5; 4th ed., 8 vols. 8vo., 1848). Valuable papers from his pen, chiefly on subjects connected with medical jurisprudence, are to be found in the medical journals; among the number are his *Recherches sur l'empoisonnement par l'acide arsénieux*. He left personal memoirs which have not yet been published.

ORGAN (Gr. *οργανον*, Lat. *organum*, an instrument), a name at the present time applied to several musical instruments that are in construction and principle somewhat closely allied; but more distinctively appropriated to the largest of these, the church organ, which may be briefly described as a wind instrument, the sounds of which are those of a great number of pipes of varying lengths, and are produced by the admission to these (as determined by the keys and stops moved by the performer) of compressed air conveyed to them along certain channels, from a bellows worked by human or other motive power. This, which from its essential feature of construction is also named the pipe organ, and from the mode of playing the finger organ, is incomparably the noblest and most imposing of musical instruments, being in majesty of tone and grandeur of effect quite without a parallel. Its name, originally designating a mechanical device or im-

plement of any sort, became at a later day appropriated in one sense to musical instruments of whatever kind; still later, to wind instruments only; and ultimately, to that which is, *par excellence*, the organ.—The early history of the organ is obscure, or indeed lost. A plausible supposition is, that the instrument may have been suggested by some modification of the Pandean pipes, such as the addition of a reservoir to receive condensed air, which should then be distributed to the pipes at the pleasure of the player. At what periods any considerable enlargement or improvements in it began to be made is not known. Ctesibius, about the middle of the 8d century B. C., is said to have invented a hydraulic organ, the *hydraulicon*; a pneumatic organ is also mentioned by some ancient writers; the distinction between the two could not have been in the employment of water and air respectively in the pipes, but merely in the use in one, but not in the other, of the power of water for supplying air to the pipes. Mersenne describes an organ carved on an ancient monument in the Mattei gardens at Rome, the form, the operation of keys, and the bellows of which closely resemble those of the present day. St. Augustine, commenting on the 56th Psalm, alludes to an instrument inflated by bellows. Pope Vitalian is related to have first introduced organs into some of the churches of western Europe, about A. D. 670; but the earliest trustworthy account is that of the one sent as a present by the Greek emperor Constantine Copronymus to King Pepin, A. D. 755. Organs were common in England before the 10th century, and are said to have exceeded in size and compass those of the continent. The largest was obtained by Elfeg, bishop of Winchester, in 951, for his cathedral. They were still very rude in construction, and of limited capacity. The keys were broad and large, and, it appears, were to be struck with the fist. The pipes were of brass, and harsh in tone. In the 12th century the compass of many of these organs, perhaps of any, did not exceed 12 or 15 notes. About this time half notes were introduced at Venice. In some of the rude instruments of the same period, a plan of concords had been arranged, such that each key in the proper compass called forth not only its own note, but by other pipes also its 5th and 8th above. William of Malmesbury, in 1143, mentions an organ, in playing which a wind "forced out by the violence" of boiling water, "passing through brass pipes, sends forth musical tones;" a device which would seem to have anticipated the harsh steam organ, or "Calliope," not long since invented in the United States. Pedals, or foot keys, were added to the organ by Bernhard, a German, in 1470; and while the improvements made have been various and by builders of many nations and periods, it seems to have been in the 15th century that the instrument reached substantially its present form. Among famous builders, the earliest were the family

of Antegnati, of Brescia, in the 15th and 16th centuries; after these, in the 18th, Serassi of Bergamo, and Callido of Venice. In England, very few instruments escaped the organoclasts in 1641; at the restoration few eminent builders survived, and foreign artists were called in. Within the past 20 years great improvements have been made in the tone, as dependent on "voicing" of the pipes; and the "touch," or quickness of response to the keys, and other mechanical arrangements, have also been greatly improved.—The tones of the church organ are yielded by many series or rows of pipes or tubes, the rows being collected into two, three, or more groups or sets, which really constitute as many distinct organs, but all connected in one arrangement. The size of the entire instrument, the number of the partial organs, and their complexity, vary much according to the requirements of special cases; and the position given to the several parts may also vary. Each row of pipes in each partial organ is, as a rule, intended to be susceptible of being played upon alone; but in a few instances a double, triple, or quadruple row is played as one. Any complete series or row, single or multiple, of the pipes, intended to sound throughout its scale as one instrument, is called a "register," and, for reasons hereafter to appear, a "stop;" if it embraces a single row of pipes, the register or stop is called simple; if two or more rows, to be played as one, compound. Of the pipes, some are mouth or flute pipes, others reed pipes; in the former, the pitch of the notes yielded is high or acute in the inverse ratio of the lengths of the pipes; in the latter, the lengths of pipe should have the like ratio to the tones yielded by the vibrating brass tongues or reeds. The pipes yielding in each single or multiple series successive notes, are fixed at their lower ends, which are conical, tapering downward, in a rack or frame, through a stout board forming the bottom of which they communicate by small openings with as many narrow channels beneath it, separated from each other by air-tight partitions. This board, forming part of what is improperly denominated the "sound board" (the organ, unlike the piano, having in fact no sounding board), may be considered as the top of an air-tight box, the wind chest, which receives air directly from the bellows by a large passage called a wind trunk. Each partial organ has its own wind chest and wind trunk; and each is really a collection of several registers or series of pipes, which stand side by side in parallel rows on the frame above the wind chest, and all opening into the channels of the sound board. Imagine a very long and somewhat broad, tight box (the wind chest), which, however, is usually of only half the breadth of the frame and sound board, transversely across and within which latter run the channels already named. These have no communication with each other, and no exit for air forced into them, save through the pipes

above, which are thus made to sound; but these channels are also closed each by a pallet or spring valve below (on the side opening down into the wind chest), so that, although the chest is kept filled from the bellows, no air can enter them, or affect the particular pipe or pipes opening into them, until this valve is depressed. To depress this valve, the player touches a key or pedal, as the case may be. The connection between the key and the valve, varying somewhat with position of the parts, is usually by the following pieces: the key or pedal, elevating a "sticker" (short link), this acting on a "back-fall" (lever), this pulling down a "tracker" (long link or slender strip of pine), this attached to and moving a "roller," by which is drawn down what is called the "pull-down wire;" and this last, passing up by a minute opening through the bottom of the wind chest, depresses the required one of the valves already referred to. In a church organ of good size (not the largest) there are usually three of the partial organs. Each has its several registers or rows of pipes, simple or compound; and of the registers, each has such a succession of pipes as will give the tones and semitones through its compass, two or more octaves. The performer on the ordinary piano, touching a white or black key, evokes one single tone or semitone from the string or wire thus agitated. But in the organ, one key struck depresses one valve, and opens and lets air into one channel. Now, this channel has opening into it from above, not only a pipe giving a certain fundamental note, but always pipes of some of the other registers of that partial organ, and usually a pipe or pipes of every one of its registers (according as each is simple or compound); and those pipes of the various registers that open into each channel, are so selected and attuned in the making of the organ, that, while as above intimated one shall give a fundamental note, the others shall give the chords—unisons, fifths, octaves, twelfths, &c.—of that note. It follows that the striking of any one key can be made to call forth at once a leading note, its unisons, and the pre-determined other chords. Suppose, then, a given white key elicits G and its chords; the black key next above will give G \sharp and its chords; the next white key, A and chords; and so on. That is, a key or pedal opens a valve, and hence a transverse channel, taking a row of pipes transversely across all the different registers of one partial organ; so that we may say each register, running lengthwise, is represented in every channel, that is, in every key (or pedal) before the performer. And this is generally true; but a few registers do not extend through an entire compass. One bank or row of keys or pedals, then, commands one partial organ. Three of these, therefore, must have three rows, two for the fingers and one of pedals. Larger organs have three, four, or more rows of finger keys. The pedals usually act on the largest pipes, which are of

wood, and in the form of hollow square prisma. It will now be seen that each partial organ, or row of keys, represents in a manner a choir or band, but one in which the chords that can be produced are of certain tones only, determined beforehand by the pipes or reeds used. The first three rows of keys connect with the three usual partial organs; the first row playing what is called the swell organ; the second the great organ; the third, the choir organ. The pedals play what is called the pedal organ. But any one of these, if played always with all its registers open, would give a uniformly forcible and consequently monotonous effect; and it is necessary therefore to place the registers also at the command of the player. This is done by means of long narrow strips of board, termed "sliders," which are let into the under side of the upper board of the wind chest, already referred to, by means of rectangular grooves cut into the board lengthwise, one in the course of each row or register of pipes. The slider fits so closely as to prevent any considerable leakage of wind, and has small holes made through it in such positions that when it is drawn out, say 2 inches, these holes communicate in straight lines from all the pipes of that register down into the several transverse channels; but when the slider is pushed in, the holes fail to match, and the corresponding register of pipes receives no air and is silent, although all the open registers of the organ be played at the time. Each simple or complex register, in each partial organ, then, has its slider; and these are drawn out or shut in by means of the "stops" or "draw-stops," which are the knobs connected with draw-stop rods appearing above the keyboard, and on each side of the performer. The connection from the knobs to the sliders is as follows: the draw-stop rod, pulled out, turns a "square," or rectangular lever turning on a centre; this moves a "trace" (link), and this a "lever" which actuates the slider. Thus a register comes also to be called a stop; and in a tolerable manner the power and capabilities of a given organ are estimated by the number of its stops or registers. The bellows, usually a single one, is at the present time placed horizontally, and is often on a level with the player, a little way within the face. The pedal organ pipes usually stand nearly on a level with the bellows; the great and the choir organ higher, the first in front; the swell organ highest, and at the back. The swell organ is so named from its use; it is entirely enclosed within a tight box of thick pine, lined with paper or leather to deaden the sound when closed; but its front is a sliding door, or several separate horizontal doors which open on axes; and these, gradually opened or closed, under the control of a pedal for this special purpose, give the effects of *crescendo* and *diminuendo*. The traces and trackers can be introduced of such lengths as required by the remoteness of the several par-

tial organs from the keys and stops, which is, in rare instances, a distance of 90 feet. An organ at Birmingham is estimated to have 44 miles of trackers. It will now be understood that, while each key commands a particular tone and its chords in one partial organ, each stop proper commands one register in one organ; and the number and kind of stops drawn out at a given time will determine the character of the tones and chords secured. But beside these, there are certain knobs which control arrangements called "couplers" (mechanical stops); one of these coupling all the keys of two partial organs, say the great and the choir, so that the player performs on both by fingering one row of keys; another coupling all three organs with one set of keys. Of these couplers the organ of Trinity church, New York, has 11—an unusual number. The registers then represent so many distinct and sometimes unlike musical instruments; certain series of pipes being made to imitate more or less closely the flute, trumpet, &c. The several registers are of pipes that are open, stopped, or half stopped, and sounding by embouchures or reeds. These circumstances not only affect the pitch, but also the *timbre* or quality; and builders further vary the quality of the tone by means of the material of the pipes—wood or metal, in the latter case either tin and lead, tin, or zinc—by the form given to the open top at which the air escapes, and to some extent by the ratio of the diameter of the pipes to their length. Pure tin gives the most clear and brilliant tone; but this, as well as the alloy of tin and lead commonly used, is liable by its weight and vibration to batter slowly at the lower end and shorten, an effect obviated by the use of wood or zinc pipes. The *timbre* of the stopped and half-stopped pipes is more dull and soft than of the open. Both the number of registers and the whole number of pipes differ very greatly, according to the tastes of builders and the requirements of purchasers. Of the stops or registers, some take their names from the quality of sound they are intended to imitate; some from the harmonic relations they bear to the leading register, the open diapason. The most usual registers (which are, of course, distributed among the several partial organs) are these: 1. The open diapason—metal mouth pipes, open at the upper end, and extending through the entire proper compass of the organ. 2. Stopped diapason—mouth pipes, generally of wood, stopped above; pitch, an octave below. 3. Double diapason—wooden mouth pipes, open; pitch, also an octave below that of 1. Generally, these are confined to the two lowest octaves of the compass, giving the lowest notes of the instrument. 4. Principal—metal mouth pipes; pitch, an octave above that of 1. This stop is first tuned, and from it all the others. 5. Dulciana—metal mouth pipes; pitch, unison with 1. The sweetness of tone is secured by increased length and narrowness of the pipes. 6. Twelfth—metal

mouth pipes; pitch, a 12th above that of 1. 7. Fifteenth—metal mouth pipes, an octave above the principal (4). 8. Flute—metal and wood pipes, in unison with 4. 9. Trumpet—reed pipes of metal, in unison with 1. 10. Clarion (or octave trumpet stop)—reed pipes of metal, an octave above 9. 11. Bassoon—reed pipes, for the lower notes, in unison with 1. 12. Cremona (clarinet)—reed pipes, in unison with 1. 13. Oboe—do. do. 14. *Vox humana*—reed pipes, in unison with 1; an imitation of the human voice, which, however, is seldom very satisfactory. To these have more recently been added the *tremolo*, a mechanical contrivance by means of which a fine, tremulous effect is given to any or all the registers of one partial organ; and also the *voix céleste*, or two rows of pipes slightly out of unison, which by interference of sound imitate the same effect. In some large organs, especially those of continental Europe, there is a great superfluity of stops, some of them absurd imitations of various instruments, and seldom useful. Among ordinary compound stops are: 1. The *sesquialtera*—4 or 5 rows of open pipes, at intervals of a 17th, 19th, 22d, 24th, and 26th above the open diapason (1). 2. Cornet—a stopped diapason, principal, 12th, 15th, and 17th. 3. Mixture or furniture stop—several ranks of pipes, nearly the same as in the *sesquialtera*, but some of higher pitch. An organ built in 1783 for a church at Pisa has 4 rows of keys, and more than 100 stops. The organ of the Seville cathedral has 100 stops and 5,300 pipes; one at Weingarten, in Swabia, 60 stops and 6,666 pipes, of which there are 7 pipes of 16 feet length, and 8 of 32 feet; one at Haarlem, 60 stops and 5,000 pipes; one at Rotterdam of 5,500 pipes, and altogether 150 feet in height; one at Baltimore, Md., 86 stops and 2,313 pipes. The three largest organs in the United States, are in New York, viz.: that of Trinity church, the compass of the great organ in which is from CCO through 5½ octaves, and which has 8 rows of keys, 43 stops, and 2,169 pipes, including a double open diapason of 32 feet; that of St. George's church, which has 47 stops, and 2,446 pipes, including one of 32 feet, and that of St. Stephen's, having 46 stops and 2,029 pipes. The compass of the leading stops in German organs is from CO (an 8-foot pipe) to F in alt.; in the English, sometimes descending to G below, or to CCO; in American, usually from CO to G in alt. This is also the compass of the swell, and of the choir organ. The stopped pipes are closed by a plug or stopper in the upper end, which is shiftable, to regulate the pitch. The half-stopped have a sort of chimney at top; and in some pipes the ear of metal on each side of the mouth is also bent inward or outward, to modify the pitch. The reeds of reed pipes are similar to those of the accordion, of brass or copper, and broader as well as of proper length. The length of pipes (in mouth pipes, the length above the orifice) is generally spoken of with

reference to that of tuning, or pitch C, which is, in the principal register, 1 foot long. The octaves below double the length successively, giving 2, 4, 8, 16, and 32 feet pipes. The last are the largest used, and these rarely; their employment is one of the circumstances giving to an organ the highest rank. In a general way, the diameter of the pipes as well as their length is varied in obtaining differences of pitch. The relations of some of the notes and of their chords to length may be exhibited thus:

Notes.	In the open diapason.		Principal, length.	Fifteenth, length.
	Length.	Diameter (about).		
CC.....	8 feet.	8 inches.	4 feet.	2 feet.
C tenor.....	4 " "	4 " "	2 " "	1 foot.
Middle, or pitch C	2 " "	2 " "	1 foot.	6 inches.
C above.....	1 foot.	1 inch.	6 inches.	3 " "

The middle C of dulciana is 2 feet 2 inches long, and about 1½ inches in diameter. Several attempts have been made in the construction of organs to avoid the imperfection of chords naturally arising where several octaves must be attuned (see HARMONY), by means of dividing the octave into more than 12 intervals. The divisions attempted have ranged from 17 to 24 intervals, the organs which were so made being called enharmonic; but the necessary complexity of the manuals and pedals, quite sufficient to alarm the practical organist, has prevented their coming into use. In the tuning of organs, some difference of practice still prevails. Some tune from C, and allow of the wolf, or discordance arising from the flatness of some of the fifths. Others tune from A, adopting equal temperament; and this, approximating nearer to the voice, interferes less with other instruments, and is more agreeable. M. Grenié of France, about the year 1810, introduced "free" in place of "beating reeds," the former being taken from instruments in form of the accordion. Mr. Bishop has stated, however, that free reeds were in use from time immemorial in China. Their advantages consist in a less liability to get out of tune, and in their admitting, to a much greater degree, of expression, or swell and diminution of tone, by varying by use of a pedal the pressure of the wind. The free reeds were applied also by Erard, but afterward fell for some time into disuse. In the London exhibition of 1851, the French and German organs had free-reed stops; in the English they were not yet in use. They are not much employed in this country. M. Grenié's reed, of wood or copper, had the form of a parallelopipedon, the tongue, a thin plate of brass, being so placed as to vibrate only in the stream of admitted air, and not against the reed, thus avoiding the harsh or uneven tone to which the old reeds were liable. The sound thus becomes quite as pure as that of the flute pipes. He constructed open reed pipes 16 feet long, the tongue being a flat slip of copper, 9.449 inches long,

1.878 broad, and 0.118 thick; their vibrations caused the pipe placed in the porte-vent and neighboring elastic bodies to tremble. See further, M. Grenié's papers in the proceedings of the French institute. For further details in respect to construction of organs, consult *L'art du facteur d'orgues*, by F. Bedos de Celles (Paris, 1766 and 1778, the last in folio, 187 plates), which, though old, is still one of the best works on the subject; Abbé Vogler's German works on organ building; G. Serassi's *Lettere sugli organi* (Bergamo, 1816); "The Organ, its History and Construction," by Rimbault and Hopkins (London, 1856); and in respect to performing, O. H. Rink's *Praktische Orgelschule* (6 parts, Leipsic), and many other popular treatises.—The Alexandre organ, so called, being constructed substantially on the principle of the harmonium, will be considered along with the latter under the head of **REED INSTRUMENTS**. In the barrel or hand organ, a bellows within the instrument is worked by turning a winch, while by the same action, by means of an endless screw, a cylinder or drum is turned, on which the tunes are set in brass pins and staples, at such distances as required by the lengths and succession of the notes, as in the pins studding the cylinder of a musical box. The pins raise keys, which press down stickers, and open pallets or valves, admitting air to the pipes required. The Apollonicon, built many years since, in London, was a gigantic barrel organ, 24 feet high and 20 feet broad; it could be played by 8 large cylinders, or by 6 performers on as many sets of keys. The tone was fine, and the effects grand and novel; but the substitution of mere mechanical action for the skill and taste of the living organist was justly deprecated, and the instrument has not come into vogue. The organolyricon is an extremely complex instrument of French invention, much on the principle of the organ, but combining more distinctly a great variety of instruments and effects, in imitation of a tolerably full band or orchestra.

ORGUNJE. See **KHIVA**.

ORIANI, BARNABÉ, an Italian astronomer, born in Garegnano, near Milan, April 15, 1753, died in Milan, Nov. 12, 1832. He early manifested a taste for astronomical science, and at the age of 23 was attached to the observatory of Brera. In 1786 he was sent to England to buy instruments, and there made the acquaintance of Herschel, with whom he kept up a correspondence during life, and on his return coöperated with him in measuring the arc of a meridian. When the Italian institute was founded, he was one of the first 30 members. On the invasion of Napoleon and creation of the Italian kingdom, he was made count and senator, having previously refused an invitation to go to France; and upon the return of the Austrians, he was confirmed in his situation as director of the observatory, which place he held

until his death. He was one of the first who calculated the orbit of Uranus; and when Ceres was discovered by Piazzi in 1801, he proved that it was a planet, and not a comet as had first been supposed.

ORIBASIIUS, a Greek medical writer, born probably in Pergamus, Mysia, about A. D. 325. He was the friend of the emperor Julian, who appointed him quæstor of Constantinople, and sent him to Delphi to attempt to restore the oracle of Apollo. Under the succeeding emperors his property was confiscated, and he was banished, but was afterward recalled, and his property was restored. There are extant 8 genuine works of Oribasius: *Collecta Medicinalia*, *Synopsis*, and *Euporista*. The first of these is valuable on account of its citations from many writers whose works are now lost.

ORIFLAMME (Lat. *auriflamma*), the banner of the Capetian kings of France. It was originally that of the abbey of St. Denis, being used in religious ceremonies, and carried also by the counts of Vexin, in their capacity of patrons of the monastery, in the wars they waged for its protection. Philip I. of France having annexed Vexin to his dominions, the charge of carrying the oriflamme devolved upon himself and his successors. Louis VI. raised it for the first time in 1124. It was disused after the defeat of Agincourt in 1415. It was a banner made of red or flame-colored silk, with 2 notches at its end, adorned with green silk tassels, and hanging from a gilded shaft.

ORIGEN, surnamed **ADAMANTIUS** from his inflexible zeal, a Christian scholar and teacher of the 3d century, born in Alexandria in 185, died in 254. His father, Leonides, was a zealous Christian, and educated him strictly in the doctrine and morality of the gospel. He went first to the catechetical school of Clement, and afterward to the Neo-Platonic school of Ammonius Saccas, where he soon became distinguished. When he was 17 years old the persecution under the emperor Septimius Severus broke out at Alexandria. Leonides was one of the first to be arrested. Origen would fain have shared his fate, and courted danger by declaring everywhere that he was a Christian. But a stratagem of his mother prevented this plan of sacrifice; and the young man, unable in decency to leave his parental home, could only write to his father, and exhort him to remain firm. Leonides was martyred, the property of the family was confiscated, and the widowed mother and her 6 younger children were compelled to look for support to Origen. A noble matron of Alexandria, pitying his condition, took him into her house, and for a time gave him the means of livelihood. But her adopted son Paul was a heretic; and Origen's horror of heresy compelling him to refuse religious communion with heretics, he preferred to open a school on his own account. Scarcely had this become established and attractive, when he was invited to succeed Clement in the catechetical school, though but 18 years old, and younger

than most of his pupils. At first he taught the profane arts and sciences, but soon confined himself to religious and scriptural instruction. Neither the clamor of the rabble nor the murder of his best pupils could interfere with his persistent teaching. He was stoned in the streets, forbidden to lecture, and driven from the city, but only to resume his work more resolutely than ever when the tumult subsided. Gradually an ascetic spirit took possession of him. He refused pay for his teaching, sold his library of heathen authors, slept upon the ground, wore but one garment and no shoes, gave up all stimulating drinks, lived on 5 pence a day, and, to secure exemption from fleshly lusts, made of himself a eunuch. He worked incessantly, and taught not only in the house, but as he walked and travelled. He dared to attend the death scenes of his scholars, and to comfort them at the stake. Among his pupils were women as well as men. After the death of Severus in 211, Origen ventured to make a journey to Rome, and his visit confirmed his purpose of doing some great work for biblical scholarship. Relinquishing part of his duties to his assistant Heraclae, he gave himself to the study of Hebrew, in which he soon became proficient above all living men. His converts became his scribes. Summoned to Antioch to meet the emperor Heliogabalus and the empress Mammea, he made such an impression by his learning and his accomplishments that the persecutions against the Christians declined. On his withdrawal to Palestine, though yet unordained, he was allowed by the bishops to teach in the Christian assemblies. To avoid this scandal, in 228, when he was 48 years old, he obtained from the bishop of Caesarea, with the consent of the other bishops of Palestine, priest's orders. This ordination was regarded by the bishop of Alexandria as irregular, and he refused to receive Origen back, or to allow him to teach or preach in Alexandria. Two councils were held, in which he was excommunicated as a heretic, deprived of the priestly office, and banished from his school. The western churches took sides with the Alexandrian bishop. But the churches in Arabia, Palestine, and Phoenicia still upheld him, and he found a welcome from the bishop of Caesarea, and work as a scriptural interpreter. The principal heresy of which Origen was accused was the denial of eternal punishment; and his writings certainly justify that charge. It is also affirmed that he taught the possible repentance and future salvation of the devil. The only evidence in support of this is, that some who afterward taught that notion cited the authority of Origen in support of their view. In the persecution under Maximin, Origen was forced to hide himself for two years in Cappadocia; and in the Decian persecution which followed, he was imprisoned, and only released after severe and protracted torture. His bodily sufferings in this persecution, added to the natural infirmities of age, brought on rapid decline, which

terminated his life. His tomb was preserved for many centuries near the high altar of the cathedral of Tyre, and was only lost when that city was destroyed during the crusades.—The writings of Origen were very voluminous, and in many kinds, critical, philosophical, polemic, and practical. Most of them, if the tradition of their large number is to be trusted, are lost. Of those still extant, the principal are the "Hexapla" and "Octapla," commentaries on the Scriptures, "On Principles," "On Prayer," "On Martyrdom," and his 8 books "Against Celsus." The "Hexapla" was an edition of the Old Testament in 6 parallel columns, in Hebrew, in Greek letters for Hebrew words, and in the 4 versions of Aquila, Symmachus, the Septuagint, and Theodotion. Two more versions were added in the "Octapla," one found in Jericho, and the other at Nicopolis in Epirus. A smaller "Tetrapla" contained only the first 4 of these versions without the original text. This splendid work, of such value in the recension and purification of the text of the Old Testament, exists at present only in fragments. Most of the MS., which appears never to have been copied, was destroyed at the capture of Caesarea by the Arabs in 658. Transcribers of his text, misreading his critical signs and marks, made many alterations, and it is not probable that the text retains its original purity. Many eminent modern scholars have labored to restore the work and edit it from these fragments. The standard edition is that of Montfaucon (2 vols. fol., Paris, 1718). The story that Origen was occupied 28 years in the preparation of this great work, has no trustworthy foundation. The commentaries of Origen upon the Scriptures cover more ground than those of any other ancient interpreter. They are remarkable for the constant use of the allegorical method. The literal sense is always secondary, and the critic never fails where it is possible to find in the simplest fact or the plainest exhortation some hidden meaning. The work of Origen "On Principles" remains only in the Latin translation of Rufinus, and in this not only is incomplete, but has been altered by the translator. Intended as a refutation of heresy, it contains some notions which seem heretical, among others the notion of the preexistence of souls, and of the souls of the stars. Editions of this work were published in Germany in 1886 by Redepenning in Leipzig, and by Sohnle in Stuttgart. The work "On Prayer" was addressed to his friend Ambrose. It takes the Lord's prayer as a model, explains this, and vindicates the meaning and worth of prayer. An edition of this work was published by Reading (London, 1728). The treatise "On Martyrdom" is a defence of death for the faith, and an admonition to constancy. In point of style it is one of the most finished of Origen's works. It was published by Wetstein (Basel, 1674). But his most celebrated work is his apology for Christianity contained in the 8 books "Against Celsus." This is regarded as

the most complete defence of the Christian religion that has come down from the ante-Nicene age. Celsus was the name of more than one distinguished sceptic, satirist, and man of science of imperial Rome; but the Celsus whom Origen attempts to refute lived in the latter part of the 2d century, was a friend of the poet Lucian, and, according to Eusebius and the church fathers, an Epicurean. In modern times, however, Michaelis and Brucker, from a more careful examination of his views, have decided that he was a Neo-Platonist. The work and opinions of Celsus are mainly known to us in the representations of his adversary. Origen answers one by one, and at length, the objections of Celsus: that the Christian assemblies were secret; that there is nothing new in their moral teaching; that the pretended miracles were really the work of magical art; that the prophecies were misapplied and unfulfilled; that ignorant men could not have been made instruments of a really noble religion; that God in Christ is an absurd idea; that Christ borrowed from Plato; and other minor cavils. Not content with this refutation, he makes a direct attack upon the system of paganism, and shows the weakness and worthlessness of this, in ritual, in doctrine and morality, as compared with the religion of Christ. In this work against Celsus Origen's acuteness as a reasoner most appears, and his philosophical system is found here most clearly stated. The collected works of Origen were published under the supervision of the Benedictine fathers, and especially of Charles de la Rue, the associate and friend of Montfaucon (4 vols. fol., Paris, 1738-'9). A more complete edition was published by Lommatsch (25 vols., Berlin, 1831-'48). The most valuable accounts of the life and writings and influence of Origen are the essay of Böhringer in the first volume of his "Ecclesiastical Biographies," the critical remarks on Origen in Neander's "Church History," and especially the "Relation of Origen's Life and Teaching" by Redepenning (Bonn, 1841). Portions of Origen's works have been repeatedly translated into French, German, and English; and interesting notices concerning the commentaries may be found in the edition published by Huet, bishop of Avranches (Rouen, 1668). In spite of minor heresies, the works of Origen are regarded by the Roman Catholic church as orthodox in the main.

ORINOCO, a river of Venezuela, South America, which falls into the Atlantic by numerous mouths between lat. 8° 40' and 10° N., after a course of about 1,500 m. Its source has never been visited by civilized man, although Sobomburgk approached within 30 m. of the place where it takes its rise. It rises in the Sierra del Parima, near lat. 8° 40' N., long. 64° 30' W., and flows W. by S. to lat. 3° 10' N., long. 66° 20' W., about 20 m. W. of the village of Esmeralda, where it bifurcates, part of its waters under the name of the Cassiquiari taking a S. S. W. direction and fall-

ing into the Rio Negro, an affluent of the Amazon, after a course of 120 m. The other branch of the Orinoco continues to flow N. W., forming part of the boundary between Venezuela and New Granada, until it receives the Ventuari on the right, about lat. 6° 20', long. 66° 30'. There it makes a sharp turn to the W. S. W., but after being joined by the Guaviare on the left at the town of San Fernando, about lat. 4°, long. 68° 10', it sweeps around to the N., receiving several smaller affluents in its course, and gradually verging toward the N. E. Near lat. 6° 20', long. 67° 45', it is joined on the W. by the Meta, which forms part of the N. boundary of New Granada, and the rest of its course is wholly in Venezuela. From its confluence with the Apure, lat. 7° 30', long. 66° 45', it flows nearly E. to the sea, its principal tributaries in this part being the Caura and Caroni, both on the right (S.) bank. About 180 m. from the sea it forms a delta, by sending to the N. a branch which divides into several streams, called the Bocas Chicas, or small mouths, some of them falling into the gulf of Paria and the rest into the open ocean. The main stream, called the Boca de Navios, is divided for about 40 m. by a line of islands leaving a channel about 2 m. wide on each side. At the great mouth of the river the breadth is upward of 60 m., but a sand bar extends across the navigable channel in the centre, with 17 feet of water. Several of the other mouths are navigable, and the main stream may be ascended for about half its length. It has more than 400 navigable tributaries, and at a distance of 560 m. from the sea is more than 3 m. wide. At Bolivar, the head of tide water, 250 m. from the sea, it is 4 m. wide and 390 feet deep. The region drained by the Orinoco, comprising an area of 250,000 square miles, is entirely occupied by immense plains, stretching from the coast chain to the Parima mountains, and from the Atlantic to the Andes, rising in some parts to the height of 1,800 feet, but in many places little above the level of the sea. The greater part of these plains is destitute of wood, but there are some dense forests in certain regions on the N. bank, and along the course of the river. The waters of the Orinoco rise from April to October, attaining the greatest height in July and August, which in the upper part of the river is from 80 to 86 feet, and in the lower 24 to 25 feet; but in one confined place they are said to rise 120 feet above the usual level. The vast plains through which the river passes are at this season to a great extent overflowed. Two remarkable rapids occur in the upper parts of the Orinoco, called the Atures and Maypures, or Apures, the one in lat. 5° 8' N., about 80 m. below the junction of the Atabapo and Guaviare with the Orinoco, the other about 86 m. lower down. These rapids are formed by innumerable little cascades succeeding each other like steps, where numerous islands and rocks so restrict the bed of the

river that, though the breadth above is upward of 8,000 feet, there only remains an open channel of 20 feet in width. It is almost impossible to pass these rapids, and in attempting it the canoes of the natives are often dashed to pieces against the rocks. From this place the river is navigable for the rest of its course.

ORIOLE, the name of a sub-family of denterostral birds of the thrush family, characterized by a bill as long as the head, broad at the base, compressed on the sides, with elevated and curved culmen and notched tip; wings long, with the first 3 quills equally graduated, and the 8d and 4th the longest; tarsi short and strongly scaled; toes moderate, the lateral ones usually unequal. In the typical genus *orioleus* (Linn.), beside the above characters, the tail is moderate and rounded, and the claws long, strong, and curved. These orioles are migratory birds, scattered over various parts of the old world; they are usually found singly or in pairs, sometimes in small flocks, on the edges of woods and in fields and orchards, feeding on fruits and insects, flying in an undulating manner from tree to tree; their notes are loud, but mellow and somewhat plaintive; the plumage is generally brilliant yellow, more or less interrupted by deep black markings; the form is stout, and the powers of flight considerable; some of them display great ingenuity in the construction of their nests. The European golden oriole (*O. galbula*, Linn.) has the body clear brilliant yellow, the wings and space between the bill and eye deep black; the quills are edged and tipped with yellowish white, which sometimes extends to the tips of the secondaries; a triangular spot of yellow on the closed wing; 2 central tail feathers black, the lateral ones with yellow tips increasing to the outside; the female is yellowish green above, shading below into yellowish and pure white, the wings brownish black with an ashy tinge; it is about as large as the blackbird, 9½ inches long. This species is found abundantly in S. Europe, Asia, and N. Africa, and some wander as far north as Great Britain and Sweden. The nest is skilfully made, of the ordinary round shape (according to Yarrell), and placed in the horizontal cleft of a branch, each side of which is included in the substance of the nest; the eggs, 4 to 6, are clear white, with brownish black spots most numerous on the larger end; the parents defend their nest with great courage. Though possessing small powers of song, their beauty makes them in request as cage birds; but they are difficult to raise, and rarely live more than two years in captivity. In the districts where they feed on figs the flesh becomes very fat, and is considered excellent eating; being very shy, it is difficult to shoot them. The African golden oriole (*O. auratus*, Vieill.) is about as large as the preceding species, which it much resembles; but the black stripe on the side of the head extends behind the eye, and there is much less black on the wings; the bill is red; it migrates southerly from equatorial

Africa. The black-headed oriole (*O. melanocephalus*, Linn.) is of a general yellow color, with the head and throat black; this is also a native of Africa. More than 20 other species are described in Africa, Asia, and the Indian archipelago.—In the genus *ephecotheres* (Vieill.) of Australia, the bill is shorter, stouter, and more curved, and the tail long and even; the species are few, frequenting the tops of lofty trees, feeding on fruits and insects. In the genus *sericulus* (Swains.), also Australian, the bill is longer and more slender, and the wings and tail moderate; these birds live in the large bushes, feeding principally upon figs. In the genus *orioleia* (L. Geoffr.), of Madagascar, the bill is as long as the head with a straight culmen, the wings long and rounded, and the tail long with the lateral feathers the shortest, each one ending in a point.—The name oriole is erroneously given to many conirostral birds of the starling family, especially to the sub-family of *icterinae* or hang-nests of North and South America; the Baltimore oriole of this group has been described under BALTIMORE BIRD.

ORION, a Greek mythical hero, according to the common account the son of Hyrieus, of Hyria in Boeotia, called by the Boeotians Candaon. He was a giant, strong and handsome, and, coming once to Chios, fell in love with Aero or Merope, the daughter of Ctenopion. To please her, he cleared the island of wild beasts; but Ctenopion constantly put off the marriage, and Orion, being intoxicated on one occasion, forced his way into Merope's chamber. To avenge this insult, the father with the aid of Bacchus and the satyrs put out Orion's eyes. He recovered his sight by going toward the east, and exposing his eyeballs to the rays of the rising sun; and on his return to Chios for the purpose of punishing Ctenopion, being unable to discover him, he went into Orete, where he lived as a hunter with Diana. Four accounts of his death are given. One is that he was killed by Diana for attempting to violate her; another, that Apollo, indignant at Diana's love for him, challenged her to hit with an arrow a distant point in the sea, which proved to be the head of Orion, who was swimming; a third, that, having been carried off by Aurora, who loved him for his beauty, Diana, to please the indignant gods, put him to death; and the fourth, that, having boasted he would clear the earth of wild beasts, the earth sent forth a scorpion which killed him. After his death he was placed among the stars, where he appears with a girdle, sword, lion's skin, and club, the brightest constellation in the northern heavens.

ORISSA, an ancient province of Hindostan, on the W. side of the bay of Bengal, between lat. 17° 16' and 22° 23' N., and long. 81° 35' and 87° 20' E., extending about 400 m. along the coast with an average breadth of 70 m.; pop. estimated at 4,500,000. It is embraced in the British districts of Outtaok, Mohurbunge, and Konjeur, the greater part of it lying in the

first named. The most important towns are Cuttack, Juggernaut, and Balasore. The chief rivers are the Godavery, which forms the S. boundary, and the Mahanuddy. The greater part of the interior consists of rugged hills and uninhabited jungles, in which wild animals, especially elephants, abound. The soil is fertile, particularly in the S. E., and the principal production is rice. The population is composed chiefly of Oorias, who are Brahmins and inhabit the low districts; Ooles or Hos, a wild hill tribe, in the north; Khonds in the middle; and Saurias or Sauras in the south. The temperature in summer is extremely sultry, the thermometer reaching 115° in the shade; and the climate is one of the most unhealthy in India. The country is consequently but thinly settled, and not well cultivated.—The downfall of the Hindoo rule in Orissa may be regarded as having been consummated in 1592, when the administration of Cuttack passed into the hands of a lieutenant of the Mohammedan king of Bengal. The rest of Orissa, except a part of Midnapore, was acquired by the English East India company by virtue of the firman, dated Aug. 12, 1765, of Shah Alum, emperor of Delhi, granting them the dewanny of Bengal, Bahar, and Orissa. Some of the hilly regions are still in possession of native chiefs, who pay a trifling nominal tribute to the British, or to their dependent the Nizam.

ORIZABA, PEAK OF, a volcano of Mexico, and the first land visible on approaching the coast in the direction of Vera Cruz. It was called by the ancient Mexicans Citlaltipetl, or Mountain of the Star (from *cittalin*, star, and *tepetl*, mountain), probably from the circumstance that when in a state of eruption the flame at its summit appeared, when seen from a distance, like an immense star on the verge of the horizon. It has an altitude of 17,873 feet. Its most considerable eruptions known to history took place between 1545 and 1566. In common with the other great volcanoes of Mexico, Popocatepetl, Tuxtla, Jorullo, and Colima, it seems to have lost most of its activity, and to be in a state of repose. The form of Orizaba is that of a very exact cone, truncated at its summit. Its top is covered with eternal snow, and its sides are so steep as almost to preclude ascent. The only ascent on record was made in May, 1848, by Lieuts. Reynolds and Maynard of the American army.

ORKNEY ISLANDS (Lat. *Orcades*), a group lying off the N. coast of Scotland, separated from it by a channel 6 or 8 m. wide called the Pentland frith, and extending between lat. $58^{\circ} 47'$ and $59^{\circ} 20'$ N., and long. $2^{\circ} 24'$ and $8^{\circ} 28'$ W. They consist of 67 islands, of which 27 are usually inhabited, and 13 are of considerable size; aggregate area about 600 sq. m., or 884,000 acres, of which about 84,000 acres are under culture; pop. in 1851, 81,455. Among the larger islands are Pomona, or Mainland, the largest of the group, with nearly half the entire population; Hoy, N. and S. Ronaldshay,

Westray, Sanday, Eday, Stronsay, Ronsay, and Shapinahay. Hoy is the only one of the group that can be called mountainous, its greatest elevation being 1,600 feet. Geologically the islands belong to the old red sandstone formation, though granite is found near Stromness in Pomona. In the peat mosses which abound throughout the group traces of ancient forests have been discovered, but at present the climate is unfavorable to the growth of trees. Marl and bog iron ore are the most important mineral products. There are no streams of any size, but springs of good water are abundant; and there are several lakes, the largest of which, in the island of Pomona, is 14 m. in circumference. There is but little frost or snow; the mean heat throughout the year is 45° , and the greatest range of the thermometer is from 25° to 75° . Agriculture is in a backward state. The herring and cod fisheries are considerable, and large quantities of lobsters are sent to London. The principal manufactures are straw plait for ladies' bonnets, and hosiery.—The same Celtic people who colonized S. and N. Britain seem to have been the original inhabitants of the Orkneys. They were visited by Agricola, A. D. 84, and were afterward favorite resorts of the piratical Northmen. In 876 Harald Harfager made a descent on the Orkneys and Hebrides, and subdued both groups. On his return to Norway he conferred the administration of his conquest on Ronald, the father of Rollo, the ancestor of William the Conqueror. In 920 Sigurd, the brother of Ronald, received this dominion from him, and afterward added to it considerable territory on the mainland of Scotland; and the two brothers thus became the founders of a long line of Scandinavian earls who affected the style of independent princes. In 1098 they became subject to the Norwegian crown; and when James III. of Scotland married Margaret of Denmark (1468), he obtained the Orkney and Shetland islands as security for her dowry. As the islands were never ransomed from the pledge, they thenceforth became attached to Scotland.—Discoveries of ancient relics have been made in the Orkney islands at various times. The most remarkable, found in 1858, consisted of massive pins, brooches, bracelets, and other ornaments, and a number of silver coins which are believed to have been contemporaneous with the earliest kings in Scottish or Scandinavian history.

ORLÉANAIS, an ancient province and government of France, situated near the centre of the kingdom, and bounded N. E. by Isle de France, E. by Champagne and Burgundy, S. by Berry, and W. by Touraine, Maine, Perche, and Normandy. With Orléonais proper, it included the districts of Blaisois, Vendômois, Dunois, Sologne, Gâtinais, Beauce or Pays Chartrain, and Perche-Gouet. It was originally the country of the Gallic tribes called Carnutes and Senones. It was watered by the Loire, Loiret, Loir, Cher, Beuvron, Yonne,

Essonne, and Loing. It has been divided into the three departments of Loir-et-Cher, Eure-et-Loir, and Loiret.

ORLEANS. I. A N. co. of Vt., bordering on Canada East, watered by the Black, Barton, Clyde, Lamoille, and Missisque rivers; area, 700 sq. m.; pop. in 1850, 15,707. It has an uneven surface, and lies between the E. and W. ranges of the Green mountains. Numerous small lakes or ponds are scattered over its surface, and Lake Memphremagog extends some distance within its borders. The productions in 1850 were 58,515 bushels of wheat, 70,306 of Indian corn, 407,132 of potatoes, 45,288 tons of hay, 81,947 lbs. of wool, 656,888 of maple sugar, and 645,160 of butter. There were 4 woollen factories, 2 founderies, 15 saw mills, 5 tanneries, 24 churches, and 4,274 pupils attending public schools. Capital, Irasburg. II. A N. W. co. of N. Y., bordering on Lake Ontario, and watered by Oak Orchard, Johnson's, and Sandy creeks; area, 405 sq. m.; pop. in 1855, 28,435. Its surface is traversed E. and W. by the lake and mountain ridges which divide it into 3 level or gently undulating plateaus, and the soil is generally fertile. The productions in 1855 were 379,155 bushels of wheat, 229,781 of oats, 436,975 of Indian corn, 171,867 of potatoes, 34,620 tons of hay, 205,802 lbs. of wool, 912,013 lbs. of butter, and 170,298 of cheese. There were 26 grist mills, 33 saw mills, 10 tanneries, 51 churches, and 10,514 pupils attending public schools. The Erie canal and the Rochester, Lockport, and Niagara railroad intersect the county. Capital, Albion. III. A S. E. parish of La., bounded N. by Lake Pontchartrain, S. E. by Lake Borgne, and S. W. by the Mississippi river; area estimated at 150 sq. m.; pop. in 1853, 162,411, of whom 16,800 were slaves. It has a low and level surface, mostly morass, submerged at high water, and fit for cultivation only on the river margins. The productions in 1850 were 32,180 bushels of Indian corn, 1,495 hhd. of sugar, and 52,505 galls. of molasses. There were 3 ship yards, 6 iron and 5 brass founderies, 8 saw mills, 118 boot and shoe factories, and in 1853 30 churches. Capital, New Orleans.

ORLEANS (Fr. *Orléans*; anc. *Genabum*, afterward *Aurelianum*), a city of France, capital of the department of Loiret, situated on the right bank of the Loire, 75½ m. by railway S. by W. from Paris; pop. in 1856, 43,256. The ancient fortifications have been demolished, to make room for gardens and public promenades. The cathedral was begun in the 13th century, and partly destroyed by the Huguenots. Its reconstruction on a new plan was begun in the reign of Henry IV., and has lately been completed. The churches of St. Aignan and St. Evverte, the old city hall, an edifice of the 15th century which is now appropriated to the museum, and the old houses of Agnès Sorel and of Francis I., are objects of attention. Orleans has a branch of the bank of France (the operations of which amounted in 1859 to nearly 51,-

000,000 francs), an academy of sciences, belles-lettres, and arts, and a large public library. There are manufactures of hosiery, woollen and cotton blankets, &c.—Ancient Genabum was destroyed by Cæsar, and, being rebuilt by Aurelianus, took his name. Attila with his Huns appeared before its walls; but the prayers of its bishop Anianus (St. Aignan) and the timely intervention of the Roman general Aëtius rescued it from danger. It was conquered by Clovis in 496, and under his successors became the capital of one of the Frankish kingdoms. It was pillaged by the Northmen in 866 and 865. Louis the Fat was crowned there in 1108, and a university was established in 1309. After the time of Philip of Valois, it became the capital of a duchy, which was bestowed successively upon various princes of the royal family. It adhered faithfully to the French kings during their long wars with the English. In Oct. 1428, the latter, under Salisbury, laid siege to the city, whose inhabitants, encouraged by Dunois and other leaders, resisted heroically; it was finally rescued, April 29, 1429, by Joan of Arc, and the enemy retreated a few days later. The states-general convened there in 1560. The Calvinists in 1562 seized upon this stronghold, which was the next year besieged by the Catholics under the duke of Guise, who died before the walls, murdered by Poltrot de Méré. In 1652, during the war of the Fronde, the duchess of Montpensier, the daughter of Gaston of Orleans, held it against the king.

ORLEANS, DUCHY AND FAMILIES OF. That region in France of which the city of Orleans was the capital formed successively a viscounty and a county under the Carolingian and Capetian dynasties. It was erected in 1344 into a duchy and peerage by Philip VI. of France, who bestowed it as an apanage upon his son Philip, who died in 1375. Thenceforth, beside several princes of the royal family who occasionally bore the title, it was held by three families or branches: 1, that of Orleans-Valois (1392–1498), consisting of 3 dukes, Louis I., the 2d son of Charles V. of France; Charles, the poet; and his son Louis II., who ascended the throne as Louis XII.; 2, the first house of Orleans-Bourbon (1626–1660), which had but one duke, Gaston, the brother of Louis XIII., who died without male issue; 3, the second house of Orleans-Bourbon (1660–1842), which originated with Philip, the brother of Louis XIV. and husband of Henrietta Anna of England; it reckons among its members Philip, the regent under the minority of Louis XV., Louis Philippe Joseph, known as Philippe Égalité during the French revolution, and King Louis Philippe; it is still extant in the persons of this king's sons, the duke of Nemours, the prince de Joinville, the duke of Aumale, and the duke of Montpensier, and of his grandsons. His eldest son, Ferdinand Philippe, who married the princess Helen of Mecklenburg-Schwerin, and died in 1842, was the last who held the title of duke of Orleans.—Of the various families of Orleans, the

following are the most important members: I. Louis, the head of the family of Orleans-Valois, born in 1371, died in 1407. The 2d son of King Charles V. by Jeanne of Bourbon, he was first styled duke of Valois, then of Touraine, and finally of Orleans in 1392. Fruitless negotiations were opened for his marriage with Mary, the heiress of Louis the Great of Hungary; and in 1389 he married Valentina Visconti, a Milanese princess, by whom he had several children. When his brother Charles VI. was seized with that madness which for nearly 40 years was productive of so many misfortunes to France, he tried to share the power with his uncles, and through the influence of Queen Isabella secured a considerable part in the administration. On the death of Philip of Burgundy in 1404, he had for a while the full control of affairs, under the title of lieutenant-general of the kingdom, in concert with the queen; but his maladministration soon made him unpopular, and John the Fearless, son of Philip of Burgundy, was looked on as a liberator when he presented himself before the gates of Paris. The rivalry between the two princes foreboded civil war; but the duke of Berry, their uncle, brought about a seeming reconciliation, Nov. 20, 1407, the rivals partaking of the sacrament together in token of amity. Three days later, within a few steps of the Montaigne palace, where he had just been visiting the queen, the duke of Orleans fell a victim to assassins hired by the duke of Burgundy. The latter at first denied all share in the crime, but soon openly avowed it, and induced a Franciscan friar, Jean Petit, to deliver an apology for it before the Sorbonne. This murder gave the signal for civil wars, which are generally styled the quarrels of the Burgundians and the Armagnacs, the latter being the adherents of the family of Orleans. II. CHARLES, eldest son of the preceding, born in Paris, May 26, 1391, died in Amboise, Jan. 4, 1465. He was carefully educated under the supervision of his mother, Valentina Visconti, and became familiar with the poems of the French trouvères, and of the great Italian writers. On his father's death in 1407, he did not evince the energy which the emergency called for; and when two years later his mother died heart-broken, he was easily persuaded to give up all thought of resentment against John of Burgundy, with whom he signed in 1409 a treaty of peace, styled the *paix fourrée* by French historians. But his party soon found a more energetic leader in Count Bernard of Armagnac, whose daughter he married in 1410, his first wife, the widow of Richard II. of England, having died the previous year. Under direction of this powerful lord, civil war was renewed, in which, while playing a secondary part, the young duke gave evidence of personal courage. The strife having been terminated by the peace of Arras in 1414, Charles joined the French army under the constable d'Albret in 1415, fought bravely in the battle at Agincourt, and was wounded, taken

prisoner, and carried to England, where during his captivity of 25 years he composed a series of miscellaneous poems, ballads, complaints, songs, and rondeaus, some of which are elegant and graceful. By the intervention of the duke and duchess of Burgundy, he was at last allowed to return to France in 1440, on condition of paying a ransom of 200,000 gold crowns and not bearing arms against England. He now married Mary of Cleves, who, 23 years later, bore him a son who was afterward Louis XII. On the death of his uncle Philip Visconti, after a fruitless attempt to take possession of the duchy of Milan, he obtained the county of Asti, his mother's dowry. In his later years he became involved in political intrigues against Louis XI., but the monarch treated him with contempt, and the duke is said to have died of grief in consequence. His poems were brought to light in 1784 by the abbé Sallier, who furnished an interesting notice of the author to the *Mémoires* of the academy of inscriptions in 1742. An edition appeared in 1808 in Grenoble; two better ones were published in 1842, by A. Champollion and Guichard. The best MS. of his poems is in the British museum. The English portion of them was printed for the Roxburgh club (4to., London, 1827). They show taste and facility in the use of the language of his long captivity. III. JEAN BAPTISTE GASTON, the youngest son of Henry IV. and brother of Louis XIII., born at Fontainebleau, April 25, 1608, died in Blois, Feb. 2, 1660. He was first known under the title of duke of Anjou, and, under the supervision of 8 successive governors, Savary de Brèves, Du Lude, and Ornano, received an education which made of a naturally weak character a pattern of restlessness, fickleness, and moral cowardice. He early showed signs of opposition to his brother's minister Richelieu, shared in all the conspiracies against him, and on every occasion was frightened into submission and the betrayal of his friends. The first whom he had to give up was his governor Ornano, who died in prison, and who in 1626 had involved him in the conspiracy for which Chalais lost his life. He then consented to marry Mlle. de Montpensier, the richest heiress in France, whom he had previously refused; she bore him an only daughter, afterward greatly celebrated under the title of Mademoiselle, and died suddenly. New but obscure family dissensions and intrigues went on during the following years, in which Gaston was constantly outwitted. He and his mother, and nearly all the courtiers, were utterly worsted by Richelieu in the imbroglia known as the *journées des dupes*, Oct. 1630. The next year, his mother having fled to Brussels, he issued a threatening manifesto against the minister, repaired to the court of Charles IV. of Lorraine, whose sister he secretly married notwithstanding the positive prohibition of his royal brother, and then, joining his mother at her place of exile, entered into a new plot which ended in open

rebellion. The governor of Languedoc, the gallant Henry de Montmorency, was persuaded to take part in it, but was deserted by Gaston at the battle of Castelnaudary, in Sept. 1632. Gaston in his fright submitted to terms dictated by Richelieu; but he soon escaped again to Brussels, where he made his marriage known. The minister, taking advantage of this avowal, made the duke of Lorraine pay for his brother-in-law's revolt, and caused his duchy to be forcibly occupied in 1634, the king in person taking the city of Bar-le-Duc. Gaston was spared, as "being of the royal blood of France, which must be respected," but received orders to retire to Blois. In 1636 he was privy to, if not an accomplice in, a plan for the assassination of Richelieu, concocted by the count of Soissons and others; but he was afraid in 1641 to help the latter in the insurrection which cost him his life. In 1642 Gaston shared in the conspiracy of Cinq-Mars, and negotiated personally with Spain; but the secret having been divulged and Cinq-Mars arrested, he gave evidence against his accomplice, which sent the unfortunate youth to the scaffold. On the death of Louis XIII. a new field opened before him, but again he proved unequal to the emergency. He evinced some personal bravery in 1644-'6 when placed at the head of the French army in Flanders, and displayed unusual good sense under various trying circumstances; but when the war of the Fronde broke out, he was found as wavering and selfish as ever, serving and betraying by turns the king, the princes, the parliament, and the popular party, and being on most occasions only a tool in the hands of bolder or more designing persons. His conduct exposed him to general indifference, if not contempt. He was finally exiled to Blois, where he spent his later years in complete insignificance. By his second wife, Marguerite of Lorraine, he had 8 daughters, who respectively married Duke Cosmo III. of Tuscany, Duke Louis Joseph of Guise, and Duke Charles Emanuel II. of Savoy. A man of some parts, and fond of the natural sciences, he was the patron of Voiture and Vaugelas, and the founder of the botanical garden at Blois. He left *Mémoires de ce qui s'est passé de plus remarquable en France de 1608 à 1685*, first published at Amsterdam in 1683. IV. PHILIP II., regent of France during the minority of King Louis XV., born at St. Cloud, Aug. 2, 1674, died in Paris, Dec. 2, 1723. The 2d duke of the house of Orleans-Bourbon, he was the son of Philip I., brother of Louis XIV., by his 2d wife, Elizabeth Charlotte of Bavaria. Until his father's death in 1701 he bore the name of duke of Chartres. He was high-minded, generous, highly gifted by nature, and accomplished by education; but from his sub-preceptor, the infamous abbé Dubois, he learned infidelity and immorality. It was Dubois who reconciled him to marrying in 1692 Mlle. de Blois, the natural daughter of Louis XIV. by Mme. de Montespan, a union no less distasteful

to his parents than to himself. The abbé was in fact his evil genius. He encouraged him in debauchery, and when at the head of the government influenced him to adopt a system of policy entirely at war with the true interests of France. The young duke early distinguished himself by his bravery at the siege of Mons in 1691 and the taking of Namur in 1692. In the latter year he was also wounded at the battle of Steenkerque. In 1693, at Neerwinden, leading the light cavalry, he penetrated through the thickest of the enemy, and, being carried so far by his ardor as to run the risk of being taken prisoner, cut his way back sword in hand. Such proofs of personal gallantry, connected with military talents, gained him little favor with Louis XIV., who did not wish a prince of the royal blood to shine too brilliantly. Philip was obliged to leave the army, and was coldly received at Versailles. This injustice and his forced inactivity preyed upon his mind, and he plunged into dissipation, but devoted a portion of his time to the pursuits of painting and natural philosophy. After the death of Charles II. of Spain, he signed, in conjunction with his father, a protest against the late sovereign's will, which entirely ignored their rights to the Spanish crown, in case the elder Bourbon line should become extinct. In 1706 the king recalled him to service, and appointed him commander of the French army in Italy, but placed him in fact under the control of Marshal Marsin. The latter, opposed by Prince Eugene, lost the battle of Turin, Philip trying in vain by skilful manoeuvres and indomitable courage to retrieve the fortune of the day. He was twice wounded. The next year he was sent to Spain, subdued the provinces of Valencia, Aragon, and Catalonia, took Lerida, which 60 years before had frustrated the efforts of the great Condé, successfully conducted several expeditions in 1708, and gained such popularity as to be received with great honors in Madrid. These successes, the manifest incapacity of Philip V., and the encouragement which he probably received from some Spanish noblemen, led him secretly to aspire to the crown which he was fighting to secure for another. His designs being suspected, he was recalled to France, subjected to a severe questioning by the king, and would probably have been arraigned before some high court had he not been protected by the intervention of the duke of Burgundy. He was finally obliged to make a formal renunciation of all his claims or pretensions to the Spanish throne, and forbidden to appear again at Versailles. Once more exiled from active life, he returned to his wonted occupations; but it was noticed that he devoted much of his time and money to chemical experiments. This, coupled with sudden and mysterious deaths in the royal family, brought him under suspicion; he was charged with having poisoned the dauphin, the duke and duchess of Burgundy, and their second son, thus

opening his way to the throne. The people of Paris were incensed by these reports to such a degree as to threaten to assault the Palais Royal, and the life of Philip was in danger. He indignantly repelled the accusation, and insisted upon a trial, his chemist at the same time offering to surrender himself to a magistrate; but Louis XIV., either from the certainty of his innocence or from motives of policy that are not quite apparent, declined an offer which would have cleared off every suspicion. Philip vindicated his good name afterward by the paternal care which he bestowed upon the infant king, then the only bar between him and the throne. By the will of Louis XIV., Philip was to be the nominal president of a council of regency which consisted chiefly of his opponents. He went to the parliament, communicated to them what he pretended that the king had said to him in his last moments, and caused them to set the will aside and place the regency in his hands, with full powers to choose his own councillors. Even the guardianship of the young Louis XV. was confided to him. During the 7½ years that he wielded power (from Sept. 2, 1715, to Feb. 22, 1723), and especially in the early part of his administration, he had to contend against many adverse circumstances. At home, on the death of Louis XIV., all was misery, ruin, and disorder. The public debt amounted to more than 8,460,000,000 livres (about \$1,200,000,000 of the present day), the yearly revenue moreover falling short of the expenditures by 78,000,000. The state was unable to pay most of the public officers and creditors; provinces had been devastated by protracted wars; scarcity was felt nearly everywhere, and commerce was completely paralyzed. As a means of relieving the treasury, the regent was advised to repudiate the debt at once; but he rejected the advice, and tried a system of retrenchment and reform. Money was recoined, all government stocks and certificates were subjected to a rigorous revision, and considerable sums were obtained from the farmers of the public revenue; but the increase of income thus obtained was scarcely felt. The regent now adopted the bold plan of a national bank proposed by John Law, which for a time (1717 to 1720) proved very successful; but the abnormal inflation of stocks, the unlimited emission of notes, and the consequent excesses in stock jobbing, ended in a terrible crash, and an increase of the public debt. This however was partly counterbalanced by the suppression of many offices and the redeeming of many branches of revenue which had previously been alienated. The regent abandoned altogether the foreign policy of Louis XIV. Yielding to the representations of Dubois, who received a large pension from the English government, and perhaps to his own resentment against Philip V. of Spain, who aspired to wrest the regency from his hands and to make good his own claims to the eventual succession of the French crown, he concluded,

Jan. 4, 1717, with Great Britain and Holland, the treaty known as the "triple alliance," by which he consented to expel the pretender from France, to discontinue the fortifications at Mardyck, to destroy the port of Dunkirk, and not to increase the French navy, giving up at the same time all right to trade in the South sea. Meanwhile Alberoni, prime minister of Philip V., was devising vast plans not only to counteract this policy, but to overthrow the house of Hanover in England and the regent in France, and restore Spain to her former rank as a ruling power in Europe. A conspiracy was plotted in Paris by the Spanish ambassador Cellamare, in which the duchess of Maine, who had entertained a deadly hostility against the regent ever since he had caused the legitimated natural children of Louis XIV. to be deprived of their privileges and reduced to the rank of ordinary peers, as well as some discontented noblemen in Brittany, were persuaded to participate. The plot was discovered by Dubois; but the regent contented himself with sending the ambassador back to Spain and the duchess to her chateau at Sceaux; only 4 of the insurgent Bretons were executed. But this outbreak led to active hostilities with Spain; and Austria having joined the "triple alliance" in 1718, war was conducted in earnest. The English destroyed the Spanish fleet, and Berwick stormed some of the northern strongholds of Spain. Alberoni, whose plans were entirely baffled, was expelled from Spain, and by the treaty of Madrid, Jan. 1720, part of western Europe was remodelled; the duke of Savoy received Sardinia in exchange for Sicily, which, as well as the duchy of Milan, was given to the emperor; while the duchies of Parma, Piacenza, and Tuscany were granted in expectancy to the eldest infant of Spain. All this was mostly the work of the abbé Dubois, who, through English influence and his master's weakness, rose to the rank of cardinal and archbishop. Owing to the recuperative power of France, rather than any successful exertions of his own, the regent, on surrendering his power to the young king, had the satisfaction of seeing the country in a condition comparatively better than at the commencement of his administration. Dubois now continued prime minister for about 6 months, and on his death the duke of Orleans resumed the reins of government in that capacity; but his constitution had been shattered by debauchery, and at the end of 4 months he died of apoplexy. By his marriage with Mlle. de Blois he had one son, Louis, born in 1703, died in 1752, and 6 daughters: Marie, duchess of Berry, who died before her father; Louise Adélaïde, Mlle. de Chartres, abbess of Chelles; Charlotte Aglaé, Mlle. de Valois, who married the duke of Modena; Louise Elisabeth, Mlle. de Montpensier, who was the wife of Louis, king of Spain, whose reign lasted only a few months; Philippe Elisabeth, Mlle. de Beaujolais; and Louise Diane, who married the prince of Conti. A natural

son, Jean Philippe, who was known as the chevalier d'Orléans, became high prior of the order of St. John of Jerusalem, and a grandee of Spain. V. LOUIS PHILIPPE JOSEPH, frequently styled Philippe Égalité, the 5th duke of his house and great-grandson of the regent, born at St. Cloud, April 13, 1747, guillotined in Paris, Nov. 6, 1793. Under the title of duke of Chartres, which he bore till 1785, he married in 1769 Louise Marie Amélie of Bourbon-Penthièvre, great-granddaughter of Louis XIV. and Mme. de Montespan, and a most worthy princess, who, owing to her brother's death, brought to her husband the rich inheritance of her house. He increased his immense fortune by speculation, and constructed three of those rows of buildings that surround the gardens of the Palais Royal. He early showed signs of opposition to the court, and in 1771 signed the protest of the princes against the dissolution of the ancient parliaments. Being rather rudely treated by Queen Marie Antoinette, who felt an instinctive antipathy to him, he conceived a violent hatred toward her, which occasionally broke forth in open hostility. In 1776 he became the head of "the princes' party," in opposition to that of the queen, and charged Marie Antoinette with being the instigator of the wrongs and insults which he received from Louis XVI. He claimed a right to be appointed grand admiral of France, but his pretensions were not allowed. In 1778 he participated as a volunteer in the naval battle of Ushant, when the highest praise, soon followed by ridicule, was bestowed upon his conduct; he was then recalled, and received the empty title of colonel-general of hussars. After a visit to London, where he lived on intimate terms with the prince of Wales, afterward George IV., he devoted himself to pleasure and dissipation. At the time of the famous trial of the diamond necklace, he bitterly denounced Marie Antoinette, and is even charged with having encouraged the libellous publications of the countess of Lamotte. He now procured his own election as grand master of the French free masons. In 1787 he appeared in the assembly of notables, and, while evincing little concern at the embarrassments that beset the throne, held secret meetings with the most ardent members of the parliamentary opposition. He openly protested against some heavy loans that were proposed by the government, and was consequently exiled to Villers-Cotterets. The popularity he thus acquired was enhanced by his lavish expenditure of money to relieve the sufferings of the people during the severe winter of 1788-'9. When the elections for the states-general came on, he was chosen at Paris, Villers-Cotterets, and Crespy in Valois. In the solemn procession that took place on the eve of the opening, he was hailed by the crowd with enthusiastic cheers, and in the assembly at once showed his sympathies for the third estate. He was among the first nobles who joined the deputies

of the commons on June 25, and aided in transforming the states-general into a national assembly. He was now charged openly with being the abettor of every revolutionary manifestation; and in fact, although he could not have originated a movement that was essentially national, his adherents had a share in all the troubles that followed, and thus favored the impression that he aspired to the crown. The garden of the Palais Royal was the usual place of meeting for popular agitators. Thence started the procession which on July 12 carried the bust of the duke of Orleans, by the side of that of Necker, through the streets of Paris; and thence came the signal for the storming of the Bastille. The events of Oct. 5 and 6 were generally ascribed to the Orleans party; the duke himself was accused by the Châtelet; but the assembly declared that there was not sufficient reason to allow one of its members to be arraigned before a tribunal. Lafayette, however, who was now exerting a sort of dictatorship, thought it necessary to keep out of the way a man who stood in the attitude of a pretender, and forced him by threats to go to London, where he remained for 8 months. On his return, July 11, 1790, while his adherents were secretly manœuvring with renewed ardor, there were some attempts at a reconciliation between him and the court; he had been at last promoted to the admiralship; an interview with the king and another with the queen seemed to have pacified angry feelings; but the treatment which he received from the courtiers estranged him for ever, and incited him to listen to still wilder projects. His elevation to the throne was spoken of; but, wavering and pusillanimous, he baffled all his adherents' hopes, while Mirabeau, who had for a moment favored his aspirations, turned from him in disgust. His want of character became especially apparent on the flight of the king from Paris, when he permitted the best opportunity for the accomplishment of his plans to escape, without even the show of an attempt. His party, however, continued to foster popular movements; they had a hand in that of June 20, and in the insurrection of Aug. 10, 1792. The duke freely mingled with the Jacobins, the Cordeliers, and the members of the revolutionary commune of Paris, whose favor he courted by the meanest arts. He now dropped his patronymic to assume the surname of Égalité, which was, in the name of the commune, bestowed upon him by Manuel. He was elected to the convention, and took his seat among the *montagnards*. He did not leave it on the trial of Louis XVI., and either of his own accord, or, as it is said, through compulsion and fear, he voted for the death of his cousin, uttering his determination in the following words: "Entirely devoted to the discharge of my duty, and convinced that all those who have made or shall make any attempt against liberty are deserving of death, I vote for death." This verdict was followed by general clamors

of indignation; and this dreadful sign of devotion to the revolution, far from redounding to his popularity, branded him as an outcast even from the ranks of the revolutionists. He was still suspected of sinister designs; and such suspicions were enhanced by the plot of Dumouriez to reëstablish the constitution of 1791 and restore royalty. The committee of general security ordered him to be arrested, April 10, 1793, as well as all the members of his family; he vainly asserted his inviolability as a deputy. In company with his youngest son he was incarcerated at the Abbaye, and thence transferred to Marseilles, where he was placed upon trial. His answers were dexterous and forcible. He denied all knowledge of Dumouriez's conspiracy, and insisted upon his unflinching devotion to the party of the mountain. The revolutionary tribunal of Marseilles found a verdict in his favor. But on the proscription of the Girondists, he was brought back to Paris, by order of the convention, Nov. 5, arraigned the next morning before the great revolutionary tribunal, found guilty on several false or frivolous charges, and forthwith sentenced to death. On hearing this verdict, he exclaimed: "Since you were determined on my death, you ought at least to have put forth more reasonable grounds for my condemnation!" and he insisted upon being at once taken to the scaffold. He thenceforth evinced remarkable self-possession, firmness, and dignity. The insults of the crowd, and the sight of his palace, before which the cart that carried him to the place of execution stopped for nearly a quarter of an hour, left him apparently undisturbed, and he met his fate without the slightest perceptible emotion.—His virtuous wife passed unharmed through the revolution, though she was detained a prisoner. On her release in 1797, she received a pension of 100,000 francs from the government, went to Spain, and thence to Palermo, where she was present at the marriage of her eldest son Louis Philippe with Marie Amélie, daughter of the queen of Naples (1809), returned to France in 1814, was treated with marked respect by Napoleon during the Hundred Days, and died in 1821. Beside Louis Philippe, she bore her husband two sons: Antoine Philippe, duke of Montpensier, born in 1775, died in 1807, who left interesting personal *Mémoires*, contained in Baudouin's and Barrière's collections, and Alphonse Léodgar, count of Beaujolais, born in 1779, died in 1808; and one daughter, Louise Marie Adélaïde Eugénie, born in 1777, died in 1847. These children were early separated from their mother and confided to the care of Mme. de Genlis, who was styled "the governor of the princes of Orleans," and conducted their education *à la Jean Jacques*. This lady at the same time held a marked influence over the father's mind, and is said to have encouraged him in his opposition to the court. VI. FREDINAND PHILIPPE LOUIS CHARLES HENRI JOSEPH, the eldest son of King

Louis Philippe and grandson of the preceding, born in Palermo, Sept. 8, 1810, killed near Paris, July 18, 1842. As the duke of Chartres, he was educated at the college of Henry IV., where he distinguished himself by cordiality and simplicity of manners and by scholarship. In 1825 he was appointed by Charles X. colonel of the first regiment of hussars, and was in garrison at Joigny when he heard the news of the outbreak of July, 1830, upon which he hastened to Paris at the head of his regiment. Being now, by the election of his father to the throne, duke of Orleans and prince royal, he went through France to distribute the new colors to the departments, made use of his popularity to suppress the insurrectionary troubles at Lyons in 1831, and in 1832 during the prevalence of the cholera visited the sick in the hospitals in company with Casimir Périer. He served in Belgium under Marshal Gérard, led the advanced guard of the French army, and had a share in the siege of Antwerp. In 1835 he repaired to Algeria, fought several battles with the Arabs, was wounded on the banks of the Habrah, and entered the town of Mascara with the triumphant army under Marshal Clausel. During the summer of 1836 he visited several courts of Germany, and there became acquainted with Helena of Mecklenburg-Schwerin, whom he married, May 30, 1837. Two years later he went again to Africa, and led one of the divisions of the army which, under Marshal Valée, forced the defile of Bibans or the Iron Gates. In 1840 he commanded the expedition against the province of Tittery, routed near Lake Kalloolah the tribes headed by Ben Salem, forced the Teniah or pass of Mouzaiah, defended by Abd el Kader himself, carried Medeah and Millanah, and thus secured to the French the right bank of the central Shelliff. In 1841 and 1842 he busied himself in improving the condition of the army; he organized the foot chasseurs, who were first named after him, and are now known as *chasseurs de Vincennes*. While preparing for a tour of inspection, he had just taken his wife to Plombières, and was going to Neuilly to pay his respects to his parents before repairing to St. Omer, when his horses became ungovernable, and in jumping from his carriage he fell on the pavement and fractured his skull. He was taken to a neighboring house, where he expired after a few hours. This sudden death sent a thrill of horror through all France, and was followed by public mourning. A chapel was built on the spot where he breathed his last; and two statues have been erected in his honor, one within the Louvre, the other on a square in Algiers. VII. HÉLÈNE LOUISE ÉLISABETH of Mecklenburg-Schwerin, wife of the preceding, born at Ludwigslust, Jan. 24, 1814, died in Richmond, England, May 18, 1858. The daughter of Prince Frederic Louis, she lost her mother, a princess of Saxony, in 1816, and her father when only 5 years old, and was educated under the supervision of her stepmother.

The brilliant festivities that followed her marriage with the duke of Orleans were saddened by a terrible accident at the Champ de Mars, by which several persons lost their lives. She shared not only the liberal views but the acts of benevolence of her husband. In spite of the antipathy the French generally feel toward foreign princesses, she had already won the affections of the people when her husband was killed. She then devoted herself to the education of her two sons: Louis Philippe Albert, count of Paris, born Aug. 24, 1838, and Robert Philippe Louis Eugène Ferdinand, duke of Chartres, born Nov. 9, 1840. She inspired them with the principles of their father, and tried to make them friends to constitutional liberty. In this she did not entirely please her father-in-law, Louis Philippe, who, a few months after her husband's death, caused a bill of regency to be presented to the two chambers, by which she was deprived of the rights which belonged to her according to previous usages of the French monarchy. She appeared with both her sons in the chamber of deputies on the eventful Feb. 24, 1848, and was on the point of being proclaimed regent when the hall was invaded by the crowd, who demanded more than the mere abdication of Louis Philippe. Amid the dreadful confusion that followed, the princess evinced anxiety only for her sons. She was finally obliged to retreat to the Hôtel des Invalides in company with her brother-in-law the duke of Nemours, then secretly removed to Bligny, and with her two sons succeeded in reaching Belgium in safety. After remaining for a time at Ems, she accepted the hospitality extended to her by her maternal uncle, the grand duke of Weimar, and settled at Eisenach. Here she lived honorably, fulfilling her duties as a mother and a Christian, and maintaining the claims of her eldest son, whom she long cherished the hope of seeing on the throne of France. When she saw his prospects blasted by the success of Napoleon III., disappointment preyed upon her mind; her health failed, and during a visit to her husband's family in England, she breathed her last without perceptible suffering. A collection of her letters has been published, and a memoir of her life translated by Mrs. Austin from the French (8vo., London, 1859).

ORLEANS, MAID OF. See AEG, JOAN OF.

ORLOFF, the name of a Russian family which rose into consequence in the early part of the 18th century, and has ever since played an important part in the history of Russia. I. IVAN, the founder of the family, was one of the corps of strelitzes who in 1689 were induced by the princess Sophia to mutiny against her brother the young czar Peter (the Great). Being included in the sentence of death by which many thousands of his comrades were destroyed, he showed such extraordinary coolness upon the scaffold that he was pardoned, and enrolled in the ranks of the army, where by his bravery he obtained a commission. He

adopted the name of Orloff. II. GRIEORII GRIGORIEVITCH, grandson of the preceding, born in 1734, died in Moscow in 1783. He early entered the military service, and became an aide-de-camp of Gen. Shuvaloff, with whose mistress, the princess Kurakin, he had an intrigue which brought him under the notice of Catharine II., then grand duchess, who took him under her protection. Rising rapidly in favor with her, he was instrumental in the deposition of her husband, Peter III., and in establishing her upon the throne, a service which gained him the first honors of the empire, including the title of count, conferred also upon his 4 brothers, who had assisted him. He aspired to the hand of the empress, but was successfully opposed by Razumoffski, Tchernitchef, and other influential men. He then meditated the formation of a kingdom on the Caspian sea, and attempted for his own advantage to establish Greece as an independent state. His fickleness, indiscreetness, and above all his inconstancy, gradually alienated from him the affections of the empress, who, as a means of ridding herself of a discarded favorite, charged him in 1771 with measures for arresting the progress of the plague in Moscow. His courage and devotion in the performance of this duty reinstated him temporarily in the good graces of Catharine, and he began again to indulge in ambitious designs. But during his absence in Wallachia to negotiate a peace with the Turks, he was supplanted by another favorite, and upon his return to St. Petersburg the empress exiled him to the castle of Tzarskoe Selo. He submitted with a good grace, and was rewarded with additional titles and domains. He however never recovered his position at court, but passed the remainder of his life in restless wanderings over Europe, or in vain endeavors to regain the imperial favor. The mortification attending his fall finally produced mental alienation, in which condition he died. He left a son by the empress, who received from the emperor Paul the title of Count Bobrinski. III. ALEXEI, brother of the preceding, born in 1735, died in Moscow in 1808. He commenced his career in the army, and attracted the favorable notice of Catharine II. by the daring part he played in the deposition of Peter III. in 1762. He was intrusted with the detention of the dethroned czar, and is said to have strangled him in prison with his own hands. His rise after this was rapid, and in 1768 he was appointed admiral of the fleet despatched against the Turks in the Grecian archipelago. By the assistance of a British officer named Elphinstone, he gained brilliant successes over the enemy at Tchesme, for which he received many marks of honor from the empress, including the surname of Tchesmenskoi, in the enjoyment of which he remained unmolested until the accession of the emperor Paul. Upon the celebration of the funeral of Peter III. by order of Paul, Orloff was forced to hold a portion

of the canopy which covered the remains of the sovereign whom 80 years previously he had aided in deposing and murdering. He was thenceforth exiled from court, and passed the remainder of his life in travelling or on his estates. He was a man of striking personal appearance, and possessed immense physical strength. IV. FEODOR, brother of the preceding, born in 1741, died in Moscow in 1796. He served in the army, and for various successes against the Turks was raised to the rank of general-in-chief. He left 4 illegitimate sons, by whom the male line of the Orloffs has been continued to the present time. V. MIHAIL, son of the preceding, born in 1786, died in 1841. He was an aide-de-camp of Alexander I., with whom he made the campaign of 1814, and participated in the negotiations resulting in the capitulation of Paris. The latter years of his life were passed on his estates. VI. ALEXEI, brother of the preceding, born in 1787, entered the army at an early age, and, after participating in the campaigns ending with the peace of Paris in 1814, became aide-de-camp to Alexander I., and colonel of a regiment of horse guards. During the formidable insurrection in St. Petersburg which followed the accession of Nicholas (1825), he manifested the utmost fidelity to the new emperor, and the energy of his movements and the loyalty of his troops contributed much to crush the rebels and to establish Nicholas on the throne. He was rewarded with the confidence of his master, bestowed during a period of 30 years, in a larger degree than upon any other subject; for which he evinced his gratitude by an unwavering devotion to the interests of the imperial family. He was made a count, appointed adjutant-general, and in 1828 fought against the Turks. In the following year he negotiated the peace of Adrianople, gaining much reputation as a diplomatist, and during the Polish insurrection of 1830-'31 he was commissioned to supervise the operations of the Russian generals in Poland. The sudden deaths of Marshal Diebitsch and the grand duke Constantine, shortly after his arrival, were attributed by popular rumor to poison, administered, as Louis Blanc insinuates in his "History of Ten Years," by Orloff, or under his direction. No just grounds for these suspicions, however, are believed to exist, the marshal and grand duke having in all probability been carried off by the cholera, which was then raging in eastern Europe. His next important service was the negotiation of the treaty of Unkiar-Skelessi between Russia and Turkey, by which the latter agreed to close the Bosphorus and Dardanelles against all ships of war except those of Russia. In 1835 he attended the coronation of the emperor Ferdinand of Austria as Russian envoy; and in all the visits of Nicholas to European courts he was his constant companion. Since 1844 he has had charge of the secret police of Russia, and has managed this vast system with an energy and skill which have caused him to be

regarded as one of the most formidable personages in the empire. In Jan. 1854, he was sent to Vienna to secure the support of Austria, or at least her neutrality, in the war with Turkey and her allies, but returned to St. Petersburg without having succeeded in either object. Since the death of Nicholas he has exercised an equal influence in the councils of his successor, Alexander II., although he probably does not sustain such intimate personal relations with him. In 1856 he represented Russia at the congress of Paris in the capacity of first plenipotentiary, and aided in negotiating the treaty of March 18, after which he was appointed by the emperor president of the grand council of the empire, a position which he still holds. He is also a prince of the empire, and has received the most important orders of the principal European sovereigns. He is a man of commanding presence and great muscular strength, of quiet deportment, and simple and elegant manners, and during his diplomatic mission to Paris was by far the most observed man in the congress.

ORME, ROBERT, an English author, born in Travancore, Hindostan, in 1728, died in Ealing, England, Jan. 13, 1801. He was educated at Harrow, began life in a counting-house, and in 1742 went to Calcutta in the East India company's civil service. In 1758 he returned to England, settled in London, and employed himself in writing a "History of the Military Transactions of the British Nation in Indostan from the Year 1745" (2 vols., 1768-'78), extending to the peace of 1763. The East India company appointed him their historiographer, with a salary of £400 a year, and he was elected a fellow of the society of antiquaries in March, 1770. He also published "Historical Fragments of the Mogul Empire from the Year 1659" (8vo., London, 1782), and left "A General Idea of the Government and People of Indostan" and "Origin of the English Establishments at Broach and Surat," both of which appeared after his death, together with the "Historical Fragments" and a life of the author (4to., 1805).

ORMOLU (Fr. *or*, gold, and *moulu*, ground, rubbed), a name given by the French to a peculiar color applied to bronze after it has been gilded. The method of producing it is as follows: The gilded articles are first rubbed with the scratch-brush, not so hard as is practised for burnishing, and then they are exposed to a more moderate heat than that employed in deadening. When partially cooled, a mixture of finely pulverized hematite, alum, and sea salt in vinegar is laid on with a brush, the burnished parts being left untouched. The pieces are then heated upon burning coals till they are hissing hot, and the color begins to change to brown. They are then plunged into cold water, washed and rubbed with a brush wet with vinegar, or, if the work is chased, with dilute nitric acid instead of vinegar. Finally they are washed with pure water and dried by a moderate fire.

ORMOND, JAMES BUTLER, duke of, lord lieutenant of Ireland, born in London in 1610, died at Kingston hall in Dorsetshire, July 21, 1688. His wardship having been claimed by King James, he was committed to the instruction of Archbishop Abbot, from whom he derived a strong affection for the principles of the Protestant religion. In 1629 he married his cousin Lady Elizabeth Preston, a union which healed dissensions that had hitherto existed between the two branches of the family. In 1632 he succeeded his grandfather as earl of Ormond. His abilities attracted the attention of Wentworth (afterward Lord Strafford), then lord lieutenant of Ireland, who predicted that "that young nobleman would make the greatest man of his family." When the Irish rebellion broke out in 1640 he was chosen commander of the royal troops, and repeatedly repulsed the rebels; but being ill supported he was forced to make terms of peace which created much dissatisfaction in England. He was, however, raised to the dignity of marquis by Charles I. and made lord lieutenant of Ireland in 1644; but after the success of the parliamentary party, he resigned his office and retired to France. Returning to Ireland, he attempted to restore the royal power, caused Charles II. to be proclaimed, and made an unsuccessful effort to capture Dublin. Cromwell passing over into Ireland, Ormond again withdrew to France, where he remained until the restoration, at which time he was raised by Charles II. to a dukedom. He was again lord lieutenant of Ireland in 1662, and held the office 7 years. In 1670, while riding in his carriage in London, he came near being assassinated by Col. Blood and 5 accomplices; and upon Charles sending to him and begging him to forgive the ruffian, then confined in the tower for a subsequent attempt to seize the king's regalia, Ormond answered "that if the king could forgive the offender for stealing his crown, he might easily forgive the attempt upon his life; and that if such was his majesty's pleasure, that was for him a sufficient reason." So convinced was Ormond's son, the earl of Ossory, that Buckingham, his father's bitter enemy, had instigated this attack, that he told that nobleman in presence of Charles, that if his father were assassinated, he should consider him guilty of it, and pistol him, even though he stood behind the king's chair. In 1676 Ormond was again appointed lord lieutenant of Ireland, and held the office until 1685. He survived "the gallant" earl of Ossory 8 years, saying in regard to him that "he would not exchange his dead son for any living son in Christendom." Ormond's life and the history of his Irish administration was written by Thomas Carte (8 vols. fol., London, 1735-'6; new ed., 6 vols., Oxford, 1851).

ORMUZ, or HORMUZ, an island in the Persian gulf, near its entrance on the N. side, in lat. 27° 5' N., long. 56° 29' E., 10 m. from the Persian coast, about 15 m. in circumference;

pop. 800. It is a mass of hills, composed of rock salt and sulphur, entirely destitute of vegetation, and containing both iron and copper ore. On the N. side are the ruins of a town which once had 40,000 inhabitants, and was a place of great trade. Albuquerque took possession of it in 1507, but the Persians, assisted by the English, expelled the Portuguese in 1622. The Persian monarch transferred the trade to Gombroon, on the opposite coast, and ordered the inhabitants to evacuate the place. About the close of the last century the imam of Muscat took possession of the island. Rock salt is prepared by the inhabitants, from which the imam derives a revenue.

ORMUZD, the supreme deity of the ancient Persians and their descendants, the Parsees and Guebres. He is the god of the firmament, the representative of goodness and truth, and the creator of the universe and of the beneficent spirits who have charge of the well being of man and all created things. According to Zoroaster, an incomprehensible being named Zeruane Akerene, the eternal one, existed from all eternity; from him emanated primeval light, and from the latter sprang Ormuzd and Ahriman or Arimanes. Ahriman became jealous of his elder brother, and was condemned by the eternal one to pass 3,000 years in a region of utter darkness. On his release he created a number of bad spirits to oppose the spirits created by Ormuzd; and when the latter made an egg containing good genii, Ahriman produced another full of evil demons, and broke the two together, so that good and evil became mixed in the new creation. The two great opposing principles are called the king of light and the prince of darkness. Ormuzd is described as "sitting on the throne of the good and the perfect in regions of pure light," or as a venerable man seated on a bull, the emblem of creation. (See GUZARAS, and MYTHOLOGY, vol. xii. p. 80.)

ORNE, a N. W. department of France, in the old province of Normandy, bounded N. by Calvados and Eure, E. by Eure-et-Loir, S. by Sarthe and Mayenne, and W. by La Manche; area, 2,355 sq. m.; pop. in 1856, 490,127. The chief rivers are the Orne, Touque, Rille, Eure, Sarthe, Huine, and Mayenne; there are a great number of ponds and marshes. The soil is sandy and unproductive, except in the valleys. Iron, plumbago, and granite are produced. Hemp, fruit, cattle, and poultry are raised for the Paris markets; needles, linens, cottons, and lace are manufactured. Capital, Alençon.

ORNITHICHNITES. See FOSSIL FOOTPRINTS, vol. vii. p. 628.

ORNITHOLOGY (Gr. *ornis*, bird, and *logos*, discourse), the department of zoology which treats of the structure, habits, and classification of birds, the 2d class of vertebrated animals. Their structure having been given under BIRDS, and their habits under their separate titles, this article will be restricted to the history and principles of their classification. Among the many methods, more or less natural, which

have been presented in the history of ornithology, such only can be introduced here as have advanced the science or have been celebrated in their day. Until after the first quarter of the 19th century most ornithologists classified birds according to the characters of the bill and feet, as expressed in the slightly varied names of the orders; since that time several continental authors, especially Oken, Nitzsch, Sundevall, Müller, Cabanis, Bonaparte, and Burmeister, have drawn attention to the care they take of their young, the song and the vocal muscles, the number and length of the quills, the scales and feathers on the legs, the number of tail feathers, the position of the hind toe, and the absence, presence, and extent of the webs, as data for the basis of a natural classification.—Aristotle, in the 3d chapter of his 8th book on animals, mentions the modes in which birds subsist, stating that some are carnivorous, others granivorous, and others omnivorous; that some are terrestrial and others aquatic, and many migratory during winter; he enumerates the names of the species then known, without descriptions except for the eagles. Pliny notices many species, but neither describes nor classifies them.—Belon, the reviver of natural history, in his *Histoire naturelle des oiseaux* (fol., Paris, 1555), classed birds by their habits and places where they are found, making the 4 divisions of birds of prey, waders, swimmers, and birds which nestle in trees or on the ground; his work is illustrated with numerous woodcuts. Gesner, of Zürich, in his *Historia Animalium*, lib. III. (1555), gives a history of birds, with a copious index and full references. Aldrovandus, in his *Ornithologia* (Bologna, 1599), follows Belon in classifying birds according to their places of habitation and the nature of their food, but adds a great number of new descriptions. Johnston (*Historia Naturalis de Avibus libri VI.*, Amsterdam, 1657) gives a condensed compilation of all that had been observed up to his time. The work of Willughby (*Ornithologia libri tres*), published at London under the superintendence of Ray in 1676, was the first systematic attempt at classifying birds; in this the land birds are divided into two groups, one having curved beak and talons, the other with the bill and claws more nearly straight; the water birds are also subdivided into waders and swimmers; there are in this work 78 folio copperplate illustrations. Ray, in the *Synopsis Methodica Avium* (8vo.), published in 1713 after his death, made some improvements upon Willughby's system; and these two furnished the basis of the classification adopted half a century later by Linnæus.—Linnæus, in the 12th edition of the *Systema Naturæ* (1766), divided the class into 6 orders: I. *Accipitres* or birds of prey; with the bill bent, and the upper mandible dilated on each side or armed with a tooth; legs short and robust, toes warty, and claws curved and sharp. II. *Picæ*, with bill convex or rounded above and edged on the lower part;

legs short and robust, but with smooth toes. III. *Anseres* (swimmers), with bill smooth, covered with an epidermis, and thickened at its point; feet with palmated toes. IV. *Grallæ*, with bill almost cylindrical, thighs half naked, and legs formed for wading. V. *Gallinæ*, with bill convex, and the upper mandible arched over the under; feet formed for walking, and the toes rough below. VI. *Passeres*, with bill conical and pointed, legs formed for hopping, and toes slender and divided. In ornithology Linnæus deserves the same credit as in the other departments of zoology, for his excellent determination of genera and his admirable system of binomial nomenclature.—Brisson, in his *Ornithologia* (4to., Paris, 1760), describes about 1,800 species of birds, arranged in 26 orders and 115 genera, whose characters are drawn from the toes and their membranes, the bill, and feathers of the legs; the descriptions are minute and accurate, and illustrated by numerous copperplate engravings. Schæffer in 1774, in his *Elementa Ornithologica*, divided birds, according to the feet, into the families *nudipedes* and *plumipedes*, as Brisson had into *fiestipedes* and *palmipedes*. Scopoli, in his *Introductio ad Historiam Naturalem* (1777), adopted the divisions of *retipedes*, having the skin of the legs divided by small polygonal scales, and *scutipedes*, having the fore part of the legs covered with unequal segments terminated on each side in a longitudinal furrow.—Latham, in his "General History of Birds" and "Supplements" (1781–1801), in his *Index Ornithologicus* (1790), and in his "Synopsis" (10 vols. 4to., Winchester, 1821–'8), was the next writer of importance on general ornithology. In the last work he divides land birds into orders: I., rapacious or accipitrine, with 4 genera and 868 species; II., pies (like the shrikes, crows, creepers, humming birds, parrots, toucans, cuckoos, woodpeckers, and kingfishers), with 82 genera and 1,320 species; III., passerine (finches, swallows, goatsuckers, thrushes, flycatchers, and starlings), with 17 genera and 1,444 species; IV., columbine or pigeons, with a single genus and 186 species; V., gallinaceous (turkeys, pheasants, grouse, bustards), with 12 genera and 210 species; VI., struthious (dodo, emu, and ostrich), with 4 genera and 8 species. He divides the water birds into orders: VII., waders, with cloven feet (herons, ibis, snipe, sandpiper, gallinule), with 20 genera and 455 species; VIII., with pennated feet (coots and grebes), with 4 genera and 29 species; and IX., web-footed (flamingo, albatross, gull, duck, penguin), with 17 genera and 859 species. He thus makes in all 111 genera and 4,824 species, of which many are ill determined and improperly made. Pennant, in his "Arctic Zoology" (1785), and Lewin, "Birds of Great Britain and Ireland" (1795–1801), adopt the system of Latham.—The abbé Bonnaterre (*Encyclopédie méthodique*, 1790) divides birds into 12 classes and 112 genera, according to the form of the bill and other minor distinctions; his system

was afterward enlarged by Vieillot.—Lacépède in 1799 (*Histoire naturelle*) divided birds into 2 sub-classes. Sub-class I. (having the legs feathered, and no toes completely united by wide membranes) contains divisions: 1, with 2 toes in front and 2 behind, large and strong, the climbers (*grimpeurs*), with 6 orders and 12 genera; and 2, having 3 toes in front and one or none behind, with the 1st subdivision of birds of prey, with strong and curved claws, embracing a single order and 10 genera; 2d subdivision, having the external toes free or united only along the 1st phalanx (*passereaux*), with 8 orders and 36 genera; 3d subdivision, having the external toes united for almost the whole length (*platypodes*), like the hornbill, kingfisher, and bee-eater, with 5 orders and 7 genera; 4th subdivision, having the anterior toes united at the base by membrane (*gallinacés*), with a single order and 12 genera. Sub-class II. (the legs without feathers, or with many toes united by a wide membrane) contains division 1, with 3 toes in front and one or none behind, with 1st subdivision, having the anterior toes united by membrane (water birds, ducks, &c.), embracing 6 orders and 17 genera; 2d subdivision, with all 4 toes united by a wide membrane (*oiseaux d'eau latirèmes*), like the cormorant and pelican, having 3 orders and 6 genera; and 3d subdivision, having the toes united at base by membrane (shore birds), with 7 orders and 26 genera; and division 2, with 2, 3, or 4 very strong toes, not united at base by membrane (*cursorés*), like ostrich and dodo, with 2 orders and 4 genera—in all, 39 orders and 180 genera. Duméril (*Zoologie analytique*, 1806) reduced the orders to 6, *rapaces*, *passereaux*, *grimpeurs*, *gallinacés*, *échassiers*, and *palmipèdes*, with 23 families.—Blumenbach, in his "Manual of Natural History" (1807), made 9 orders. A. Land birds: I., *accipitres*; II., *levirostrés*; III., *pici*; IV., *coraces*; V., *passeres*; VI., *gallina*; VII., *struthiones*. B. Water birds: VIII., *grallæ*; IX., *anseræ*. Shaw, in his "General Zoology" (1809-'12), adopted the 6 orders of Linnæus; but Mr. Stephens, in his continuation of the work, admitted many of the modifications of Mr. Vigors's system (mentioned below). Meyer and Wolff (*Almanach des oiseaux de l'Allemagne*), in 1810, made the 11 orders of *rapaces*, *coraces*, *pici*, *alciones*, *ocines*, *chelidones*, *columbæ*, *gallina*, *cursorés*, *grallæ*, and *natatores*; this seems to be the first work in which the terms *ocines*, *alcyones*, and *chelidones* are applied to the orders of birds. Illiger (*Prodromus Systematis Mammalium et Avium*, 1811) gives the 7 orders *scansores*, *ambulatorés* (including the 2d, 4th, 5th, and 6th orders of Meyer), *raptatores*, *cursorés* (including gallinaceous birds and pigeons), *cursorés* (ostrich, bustard, plover), *grallatores*, and *natatores*, with 41 families and 147 genera.—Cuvier (*Règne animal*, 1817) preserved the 6 orders of Linnæus, founded on the characters of the beak and feet, except that he substituted the previously used term of *scansores* for those

of the *pici* which have 2 toes before and 2 behind, placing the remainder among the *passeres*. His orders are: I., *accipitres*, divided into diurnal (hawks, &c.) and nocturnal (owls); II., *passeres*, divided into tribes *dentirostrés* (like shrikes), *levirostrés* (swallows and goatsuckers), *conirostrés* (crows, buntings, and starlings), *tenuirostrés* (humming birds), and *syndactyli* (kingfishers); III., *scansores* or climbers (woodpeckers and parrots); IV., *gallina*, or birds resembling the domestic cock; V., *grallæ* or waders, divided into *brevipennes* (ostrich), *pressirostrés* (bustards), *cuthirostrés* (cranes), *longirostrés* (ibis, curlew, snipe), and *macrodactyli* (rail, jacana); VI., *palmipodes*, divided into *brachypteri* (penguins and grebes), *longipennes* (terns and petrels), *totipalmes* (pelicans), and *lamellirostrés* (ducks). This is essentially followed in the article "Ornithology" of the "Encyclopædia Britannica," and by Milne-Edwards (1855).—Vieillot in 1817, and in the article *Ornithologie* of the *Nouveau dictionnaire d'histoire naturelle*, made 5 orders: I., *accipitres*, diurnal and nocturnal, with 4 families; II., *syloicola*, with 2 tribes, *sygodactyli* and *anisodactyli*, equivalent to the climbing and passerine birds of other authors, with 30 families; III., *gallina*, with families *nudipedes* and *plumipedes*; IV., *grallatores*, with the tribes *di-tridactyli* and *tetradactyli*, with 15 families; and V., *natatores*, with the tribes *teleopodes*, *ateleopodes*, and *ptilopteri*, with 7 families.—Temminck (*Manuel d'ornithologie*, 2d ed., Paris, 1820-'40) modified the systems of Meyer, Illiger, and Latham, and made 16 orders, comprising 202 genera. His orders are: I., *rapaces* or birds of prey; II., *omnivores* (crows, rollers, starlings); III., *insectivores* (thrushes, shrikes, flycatchers, warblers); IV., *granivores* (larks, buntings, finches); V., *sygodactyli* (cuckoos, toucans, parrots, woodpeckers); VI., *anisodactyli* (creepers and humming birds); VII., *alcyones* (bee-eaters and kingfishers); VIII., *chelidones* (swallows and goatsuckers); IX., *columbæ* or pigeons; X., *gallina*; XI., *alektorides* (agami); XII., *cursorés* (ostrich and bustard); XIII., *grallatores* or waders; XIV., *pinnatipedes* (coots and grebes); XV., *palmipedes*, swimmers; XVI., *inertes* (apteryx and dodo). This is followed by Naumann in his *Vögel Deutschlands* (18 vols. 8vo., Leipsic, 1820-'44), and is adopted in Stark's "Elements of Natural History" (Edinburgh, 1828).—De Blainville (1823) called birds *pennifera*, and made the 9 orders of *prehensores* (parrots), *raptatores*, *scansores*, *saltatores* (passeres), *sponsores* (pigeons), *gradatores* (*gallina*), *cursorés*, *grallatores*, and *natatores*. Beside this system, founded on the characters of the legs and feet, he proposed another, developed by L'Herminier in 1827, based on the anatomical peculiarities of the sternum or breast bone. (See *Annales de la société Linnéenne de Paris*, vol. vi.) This is interesting as illustrating several obscure points in the structure of birds, and as furnishing many secondary characters useful in classification. He makes 2 sub-

classes: I., normal birds, in which the sternum is provided with a crest more or less developed, and with the 8 bones in the shoulder distinct and simply in contact, including 84 families of ordinary birds, from the hawks to the penguins; II., abnormal birds, in which the sternum is formed of 2 pieces, originally separated, united on the median line into a single plate, of various forms, but always without bony crest or keel; the shoulder bones, distinct in the young, are consolidated in the adult; this includes the single family of *cursor* (ostriches). Latreille (1825) divided the terrestrial birds into the orders *rapaces*, *passerorum*, *grimpours*, *passerigalles* (pigeons and guans), and *gallinacés*, and the water birds into *échassiers* and *palmipèdes*, describing 252 genera.—Leeson (*Manuel d'ornithologie*, Paris, 1838), though in his text he adopts the system of Cuvier, gives another in his introduction, as follows: Section I., terrestrial birds, with the orders: 1, *insessores*; 2, *passerini*; 3, *rapaces*; 4, *rasores*; and 5, *heterosoma* (ostriches). Section II., aquatic birds, with the orders: 6, *grallatores*; 7, *pinatipèdes*; 8, *natatores*; and 9, *paradeaux* (including the genus *ornithorhynchus*, now universally recognized as a mammal). Straus-Durckheim (*Traité d'anatomie comparative*, Paris, 1848) adopts the 6 orders of Cuvier, adding a 7th, *nyctériens*, for the nocturnal birds of prey. Gray ("Genera of Birds," 4to., London, 1844-'9) makes the system of Cuvier the basis of his classification, separating, however, the *columba* as an order from the *gallina*, and the *struthiones* from the *gralla*, forming 8 orders with 49 families.—The famous quinary system of classification was for many years in vogue in England, and exerted considerable influence upon ornithology by calling attention to many affinities and analogies previously overlooked. Macleay, its founder (*Hora Entomologica*, London, 1819-'21), assumes that all animals of a group must be analogous to those of every other group, beside forming a circle in themselves; and he therefore arrays them in circles and groups so as to bring out external analogies, without much regard to structural affinity. Vigors ("Transactions of the Linnean Society of London," vol. xiv., 1835), following out his quinquennial and circular arrangement of affinities, adopts the 5 orders of *raptores*, *insessores*, *rasores*, *grallatores*, and *natatores*, characterized respectively by their feet

adapted for tearing, perching, scratching, wading, and swimming. These 5 groups, which he arranges as circles, are connected together as follows: the *raptores* to the *insessores* by the owls of the former and the goatsuckers of the latter, the immediate passage being made by the Australian genus *podargus* (Cuv.); the pigeons are intermediate between the perching and gallinaceous birds, but belong essentially to the latter, and these orders come nearest together at the insessorial plantain eaters and the rasorial curassows; the passage from the gallinaceous birds to the waders seems to be between the bustards of the former and the genera *calicnemus* (Cuv.) and *peophia* (Linn.) of the latter; the passage from the waders to the swimmers is by the coot (*fulica*, Linn.) of the former and the Australian goose (*cereopsis*, Lath.) of the latter; the swimmers are brought back to the *raptores* by the frigate bird (*tachypetes*, Vieill.) of the former, and probably some of the *gypogeranida* of the latter. The affinities are thus represented (*op. cit.*, p. 509):

Each of these 5 tribes in each of the 5 orders is capable of being again subdivided into 5 families, which may be arranged in circles similarly connected. Swainson (Lardner's "Cabinet Cyclopædia," vol. xiii., 1837) adopts the same 5 orders and the general quinary arrangement, and expresses the analogies existing between birds and mammals in the following tabular form:

1. Typical.	<i>Insessores.</i>	Prehensile.	<i>Quadrumanæ.</i>
2. Sub-typical.	<i>Raptores.</i>	Carnivorous; retractile claws.	<i>Fera.</i>
3. Aquatic.	<i>Natatores.</i>	Feeding and living in the water.	<i>Osteacea.</i>
4. Suctorial.	<i>Grallatores.</i>	Jaws much prolonged.	<i>Glossæ.</i>
5. Rasorial.	<i>Rasores.</i>	Domestic; feet for walking.	<i>Ungulata.</i>

He connects the 1st and 2d, 3d and 4th, and 4th and 5th orders by the same tribes as does Vigors; but he is inclined to connect the 2d with the 3d by the *didida* (dodo), which he places erroneously near the vultures, instead of the *gypogeranida*, which he considers either the grallatorial or possibly the rasorial type of the *raptores*; he connects the 5th with the 1st

by the *megapodida* instead of the curassows. According to the principle of these systems, birds are connected on the one hand with reptiles through the pterodactyle, and on the other with mammals through the ornithorhynchus and the ostrich. Though these affinities cannot be made the basis of a natural classification, they are interesting, ingenious, and to

some extent philosophical.—The first and most learned of the German physiophilosophers, Oken, in various works from 1809 to 1848, published his system of classification, in which birds are called ear animals, in the division according to the senses, because in them for the first time the external auditory meatus as well as the cochlea is exhibited in perfection; birds are also nerve animals, in the anatomical division, as they have a complete nervous system with cerebrum and cerebellum. They belong to his 2d province, of *sarcosoa*, 4th circle or flesh animals, and 12th class or *otozoa* or *neurosoa*. They are the first encephalic animals, as the brain defines the head, which is here for the first time freed from the trunk and placed upon a long neck far removed from the thorax, hence also called cervical animals; the caudal vertebrae, on the contrary, are less than in other classes. Birds are capable of instruction, affection, imitation, gratitude, and other mental manifestations not seen in reptiles and fishes. They are the closest repetition of insects, the thorax predominating over the rest of the body, with large respiratory muscles; their lungs are a cluster of insect tracheae, full of foramina through which air penetrates all over the body, as in insects; the intestine lies in the air, and the bird to a certain extent breathes from it; the whole bird is lung, and its body a thoracic cavity, as the latter is a sexual cavity in the fish and an abdominal cavity in the reptile; the food is crushed in a muscular stomach, as in insects; a bird is an insect with fleshy limbs, and a feather is an insect's wing. With the bird, for the first time, the voice proper breaks forth; "the bird speaketh the language of nature." Swainson (*op. cit.*) expresses the same idea, when, after stating that the typical characters of each are a body furnished with wings, he says: "Birds are the butterflies of the vertebrated animals, not merely in the imagery of poetry, but in the sober language of science." In Oken's "Physiophilosophy" (Ray society edition, London, 1847) are given two great divisions of birds, according as the young require to be fed by the parents or not, the former being the lowest; this principle of division, first published in 1821, has retained its place in ornithological science, and lies at the base of the systems now generally followed in Europe and in this country. His divisions are: A. Splanchnic birds, which remain in the nest and are fed, with short neck and feet, 4 ununited toes, and pointed beak. In this division are the orders: I. Protozooid birds (*tenuirostræ*), some of them very small, insectivorous, slender-formed, with awl-shaped bill and brilliant plumage, employing feet and tail in climbing; with families: 1, infusorial birds (humming birds and creepers), the bill bringing to mind the proboscis of insects; 2, polypary birds or woodpeckers; 3, aculephian birds or cuckoos. II. Conchozooid birds (*conirostræ*), perchers, granivorous, with powerful bill and muscular gizzard; with families: 4, mussel

birds or sparrows; 5, small birds or crows; 6, kraken birds or parrots. III. Ancylozooid birds (*dentirostræ*), with families: 7, worm birds, *cantores* or songsters; 8, crustacean birds or flycatchers; 9, ptilotoid birds (*rapaces*). B. Sarcosæ birds, which run about soon after being hatched, feeding themselves; the bill is obtuse in most; they are good walkers, runners, or swimmers, and some are good fliers. This division contains the orders: IV. Sarcosæ birds, with long neck, comprising the families: 10, fish birds (*nataiores*), approximating to fishes in the webbed and posteriorly inserted feet, closely set plumage, and swimming, diving, and fish-catching habits; 11, reptilian birds (*grallæ* or waders), with very long neck, bill, and legs, "having a frog's body, with its long feet, and a serpent's neck with a tortoise's head;" 12, typical birds (*gallinæ*). V. Sensorial birds, unable to fly, with family 13, thricozooid birds (bustard, cassowary, and ostrich), having mammalian affinities. Fitzinger's classification (1848) is based upon this of Oken. Cuvier (1818-'28), in his *Traité d'anatomie comparée*, ranks birds in his 6th class or *cephalo-thoracosa*, characterized by great development of the respiratory organs. He makes the orders: I, *nataiores*, having relations with reptiles, especially such of its members as fly poorly or not at all (like the penguins); II, *vadentes* or waders; III, *predentes*, with the sub-orders *rapaces*, *passeres*, *scanores*, and *gallinæ*; and IV, *incedentes* or struthious birds, having relations to mammals. Ehrenberg (1886) ranks birds as the 2d and last class of the *nutritia* or animals which take care of their young; this division is not strictly natural, as some reptiles and fishes have a care for their progeny. Without accepting the theory of progressive development which seems naturally to arise from the system of the great German physiophilosopher, much that is valuable in the way of anatomical and physiological relation has been suggested by his researches.—The embryological systems of classification next deserve attention. The eggs of birds have generally been selected for investigations in embryology, and, under the examination of Döllinger, Von Baer, and Pander and D'Alton, have furnished most important discoveries; the unity of anatomical structure in all vertebrates is confirmed by the common structure of the primitive egg, and the order of classification from anatomical evidence by the metamorphoses which each class undergoes to its full development. The bird goes through its fish-like and reptilian structure and form; the only difference between the egg of a bird and a mammalian ovum, as to external covering, is that the former has a hard shell when laid protecting the immature chick, while in the latter the envelopes remain membranous, having a peculiar connection with the maternal body which is not severed until the birth of the young. Von Baer (1828) places birds in his doubly symmetrical type, whose embryos acquire an allantois, but have no umbilical cord,

having wings and air sacs. Van Beneden (1845) ranks birds as the 2d class of his *hypocotyledones* or hypovittellians, in which the vitellus enters the body from the ventral side; he makes the orders *psittaceae*, *rapaces*, *passeres*, *columbae*, *gallinae*, *struthionae*, *grallae*, and *palmipedes*. Vogt (*Zoologische Briefe*, 1851) makes two series of birds: I., *insectivores*, with orders *columbae*, *ocineae*, *clamatrices*, *scansores*, and *raptatores*; and II., with orders *natatores*, *grallatores*, *gallinaceae*, and *cursorae*. Prof. Agassiz ("Proceedings of the Boston Society of Natural History," vol. iii. p. 42, 1848, and 19th "Lecture on Embryology," Boston, 1849) gives the results of some observations on the structure of the bird embryo, from which it appears that the limbs are not at first developed in the form which is to be permanent; the legs and wings are not formed as such, but as fins; in all the orders of birds, with their various powers of locomotion, the legs and wings are uniformly webbed like the fins of fishes; in the same manner the primary condition of the heart, lungs, and other organs of a bird is that of these organs in a fish. This would indicate that the web-footed birds are lower in the scale than those with divided toes; and that the union of all the former into one group, however different the structure of their wings, plumage, and internal organs, and their mode of life—the almost wingless penguin with the swift-flying ocean birds, the hook-beaked predaceous gulls with the flat-billed and timorous ducks—must be an unnatural arrangement. In the words of this lecture: "It is probable that we shall soon see a rearrangement of the class of birds, which will be classified on other grounds, and leave in each group some swimming types and some types with divided fingers, which may be combined by some higher characters." The examination of the feet of an embryo robin, swallow, warbler, and finch, showed all 4 toes directed forward and webbed, while in the mature birds they are separate, 3 directed forward and one backward; he found the bill of the immature robin resembling that of a vulturine bird, indicating the comparatively low type of the latter; indeed some water birds, like *lestris* (hawk-gull), have a bill very greatly resembling that of the vultures; some birds of prey also resemble water birds in the rudiment of a web between the toes. He regards birds which have all their toes directed forward as of a lower type than those in which one is directed backward, as, for instance, the pelicans and cormorants among water birds, and the swifts (genus *cypselus*, Ill.), among swallows; a similar idea was broached by Sundevall in 1835. In Prof. Agassiz's classification, as given in vol. i. of the "Contributions to the Natural History of the United States" (Boston, 1857), birds form the 7th class of vertebrates, with 4 orders, *natatores*, *gralla*, *rapaces*, and *insectivores* (including *scansores* and *accipitres*).—Oken appears to have first proposed a classification of birds according as the young are or are not

fed by the parents. Sundevall (*Kongl. Vetenskaps-Academiens Handlingar*, Stockholm, for years 1835 and 1843) adopted this principle of division, and made use of the position of the hind toe and the powers of song in his classification. His sections are: A. *Aves altrices*, which nourish their young in the nest, having either the thumb or the external toe turned back and entirely resting on the ground. These comprise the divisions or legions: I. *Volucres* (*passeres* of Cuvier), typical flying birds, with the thumb only turned back, containing the orders: 1, *passeres*, with 4 families; 2, *ocineae* (singers), with 28 families. II. *Gressores* or walkers, containing the orders: 3, *macrochires*, with the 2 families of swallows and humming birds; 4, *pici* (woodpeckers), with the outer toe also turned back, having 2 families; 5, *psittaci* (parrots), having the external toe turned back, with a single family; 6, *coccyges*, with scaled tarsi, with 10 families of cuckoos, kingfishers, trogons, &c.; 7, *accipitres*, with 4 families of owls, hawks, and vultures; 8, *pullastra*, intermediate between the *gallinae*, cuckoos, and *accipitres*, with 4 families of guans and pigeons. B. *Aves praecoces*, whose young seek their own food soon after birth, having the thumb elevated or absent. III. *Cursorae*, runners, with orders: 9, *gallinae*, with whole tibia feathered, with 4 families of pheasants and grouse; 10, *struthionidae*, having wings without feathers, the ostrich family; 11, *alektorides*, having a very small or no thumb, with 4 families of bustards and screamers; 12, *gralla* (waders), with 4 families of herons, storks, rails, and sandpipers. IV. *Natatores* or swimmers, with the femur and base of tibia included under skin of abdomen, with orders: 13, *gavia*, having the thumb free and elevated or wanting, with 2 families of gulls and petrels; 14, *steganopodes* (Ill.), with thumb long, partly elevated, joined by membrane or lobed, with 4 families of pelicans and gannets; 15, *anserae*, having the thumb short and free, with the single family of ducks; and 16, *urinatores*, having the thumb small and free or absent, ejecting their urine forcibly, with 8 families of loons, guillemots, and penguins. Keyserling and Blasius (*Wirbelthiere Europa's*, Brunswick, 1840) make the 6 orders *rapaces*, *scansores*, *ocineae* (singing birds), *gallinaceae*, *grallatores*, and *natatores*.—Though Cuvier long before had drawn attention to the peculiar muscular apparatus of the larynx in true singing birds, and to its inferior development or absence in others, J. Müller (Berlin "Transactions," 1845) first laid stress on its importance as an element in classification; and on this and on corresponding external characters, Cabanis, and after him Burmeister (*Thiere Brasiliens, Vögel*, Berlin, 1856), divided the *insectivores* into *strisores*, *clamatrices*, and *ocineae*. According to Cabanis, the fusion of all the scutellæ of the tarsus into a continuous envelope or "boot," without indication of divisions, is the type of the highest bird, and the position of the families and genera

in the scale is high according to their approach to it and to the reduction in size of the first quill. Oabanis (*Archiv für Naturgeschichte*, Berlin, 1847) makes the 10 orders of *ocines*, *clamatores* (crying birds, like shrieks, rollers, and kingfishers), *strisores* (having no power of modulating the voice, like swallows and goat-suckers), *scansores*, *columba*, *raptatores*, *rasores*, *cursores*, *grallatores*, and *natatores*; the first 4 orders compose a sub-class named *insectores* by

Sub-class ALTRICES.
Order I. PRITACH.

American.....Old World.
II. ACCIPITRES.
III. PASSERES.
Oocines.....Volucres.
IV. COLUMBÆ.
Pterodactyls or *inapti* (dodo, &c.).....
Gyrantes (doves, &c.).....
V. HERODIONES (herons).....
VI. GAVIÆ (gulls, &c.).....
Totipalmi.....Longipennes.

He afterward transferred the *urinatores* (or *brachypteri*) from *anseræ* to *gaviæ*, and made a separate order of the *ptilopteri* or *impennes*. From this table it will be seen that the dodo and its congeners of the *altrices* represent the ostriches among the *præcoces*, the doves the gallinaceous birds, the herons the sandpipers, and the gulls and pelicans the ducks, &c., each in their respective sub-classes; this parallelism of physiological character in the *altrices* and *præcoces* corresponds, as Prof. Baird remarks in the work mentioned below, to a certain degree with that which prevails between marsupial and placental mammals; and the former should no more be combined in the same order than should the latter.—Van der Hoeven ("Handbook of Zoology," English translation, 1857) makes the following 6 orders: I., *natatores*, with 4 families; II., *grallatores*, with 7 families; III., *gallinæ*, with 8 families; IV., *scansores* or *eygodactyli*, with 7 families; V., *passerini* (*ambulatores* of Illiger and *anisodactyli* of Vieillot), some singers (*ocines*), and others without muscles for song (*clamatores* of Wagner), with 25 families; VI., *raptatores*, with 8 families.—Prof. S. F. Baird ("Pacific Railroad Survey," vol. ix., Washington, 1858) adopts the following classification, chiefly from Keyserling and Blasius, Oabanis, Bonaparte, and Burmeister: orders I., *raptores*; II., *scansores*; III., *insectores*, with sub-orders *strisores*, *clamatores*, and *ocines*; IV., *rasores*, with sub-orders *columba* and *gallinæ*; V., *grallatores*, with sub-orders *herodiones* and *gralla*, the latter with Burmeister's tribes of *limicola* and *paludicola*; VI., *natatores*, with sub-orders *anseræ* and *gavia*, the latter with the tribes *totipalmi*, *longipennes*, and *brachypteri*. He gives many details on the divisions into sub-orders, tribes, and families, which, though highly instructive, cannot be introduced here.

Bonaparte in his catalogue of 1842.—Prince C. L. Bonaparte, in his *Conspectus Avium* (Leyden, 1850-'57), and in vol. xxviii. of the *Comptes rendus* of the Paris academy (for Oct. 31, 1853), treats of the classification of birds. In the article in the *Comptes rendus* he gives the following table, in which the two great sub-classes are made with reference to whether the young require or not to be fed by the parents:

Sub-class PRÆCOCES.

VII. STRUTHIONES (ostriches).
VIII. GALLINÆ (gallinaceous birds).
Passeripedes.....*Grallipedes*.
IX. GRALLÆ (sandpipers, &c.).
Cursores.....*Alectorides*.
X. ANSERES (bill with lamellæ).
Lamellirostres.....*Urinatores*.....*Ptilopteri*.

It may be well to mention, for the sake of comparison, that Burmeister divides the order *insectores* into the sub-orders *clamatores* and *ocines*, the former including *strisores* and *tracheophones* (flycatchers) as tribes. This volume is especially valuable for its copious alphabetical list of authors on ornithology, most of which are accessible to the student at the library either of the Smithsonian institution at Washington or of the academy of natural sciences in Philadelphia.—None of these classifications are entirely satisfactory, and all are more or less unnatural and artificial; it is probable, however, that a true classification may in time be expected from the combination of the anatomical, physiological, and embryological systems, in the direction now industriously followed by the German ornithologists. There is an undoubted relation of the complexity of structure and size of the cerebellum to the complexity of movements; this part of the brain in a gallinaceous bird, with feeble powers of flight, is relatively smaller than in the active birds of prey and other rapid fliers; perhaps this comparison carried out might assist in a natural classification of birds, as the complexity of the cerebral hemispheres of mammals has led, under Owen's researches, to a new arrangement of these highest vertebrates. There is no department of zoology that has been so extensively and elegantly illustrated as that of ornithology; reference may be made to the figures in the works of Sloane, Oatesby, Seba, Edwards, Albinus, Brisson, Sepp, Browne, Latham, Pennant, Hardwicke, Bewick, Donovan, Lewin, Shaw, Jardine and Selby, Buffon, De-marest, Le Vaillant, Temminck, Spix, Vieillot, Rüppell, Audubert, Horsfield, Lesson, Swainson, Gray, Gould; and in America to Wilson, Bonaparte, Audubon, De Kay, Cassin, and Baird; to the "Proceedings of the Zoological Society"

of London (descriptions of Mr. Selater and others), and the various illustrated works, the results of the national expeditions sent out by England, France, the United States, Russia, Holland, &c. Among the magnificent works may be mentioned the 1,008 *planches enluminées* of Buffon (fol., Paris, 1770-'86); the 600 *planches coloriées* of Temminck; Le Vaillant's birds of Africa, parrots, birds of paradise and rollers, promerops, and rare birds of America and India, in all about 570 plates; Edwards's 862 plates of uncommon birds; Vieillot and Audubert's nearly 180 plates of birds of brilliant plumage; Gould's series of the birds of Australia, Europe, the humming birds, trogons, &c.; Audubon's 425 plates in folio of North American birds. America has not produced any original system of classification of birds; but the writings of Nuttall, Wilson, Bonaparte, Audubon, De Kay, Baird, Lawrence, and Cassin have well illustrated the ornithology of this country; many new and beautiful species have been added of late years, which have been figured by Cassin in his "Supplement to Audubon," and by Baird in vol. x. of the Pacific railway report, and vol. ii. of the Mexican boundary survey; the "Proceedings of the Philadelphia Academy" of late years have been rich in descriptions of new species.—Though birds have great facilities for locomotion, they are for the most part restricted within the limits of zoological provinces; while the same species may be found throughout the arctic zone, there is no such identity in the temperate and torrid zones. In the arctic fauna the species are few, but the number of individuals is immense, being mostly aquatic and of dull and uniform plumage; in the temperate fauna there is much greater variety, especially in the climbing, perching, gallinaceous, and rapacious groups; in the tropical fauna the number of species is very great, and the plumage exceedingly brilliant. There are probably 6,000 species of birds, of which about five sixths are known. Birds existed on the earth before the present geological epoch, but their remains in a fossil condition are comparatively rare, for several reasons; the absence of comparatively imperishable teeth lessens the probability of finding their fossil traces, and the lightness of their dead bodies would cause them to float, exposing them to be devoured by carnivorous animals, and giving them rarely a chance to settle quietly and unmutated to the bottom of the sea. The oldest date claimed for birds is the new red sandstone epoch, where in the Connecticut valley Dr. Hitchcock and others have found tracks which they pronounce those of birds. (See Fossil Footprints, and Dr. Hitchcock's "Ichnology.") The opinion now, however, is general that these tracks were made by reptiles and not by birds or bird-like animals; *a priori*, we should not expect to find birds, warm-blooded and quick-breathing animals, contemporary with the great reptiles, and preceding the marsupial mammals; more-

over, their traces are not found in the succeeding jurassic period, which would be an exception to the rule of continuous existence in the vertebrated series; these alleged birds were also waders, whereas we should expect to find the lowest birds, the web-footed, appearing earliest in time; for these and other reasons, and from a more careful examination of the tracks, it may be doubted if any birds existed at the epoch of the new red sandstone. Birds certainly did appear in the cretaceous period; birds of prey have been found in the tertiary and diluvial; *passeres* in the same; *gallina*, rare in the tertiary, are abundant in the diluvium; among *cursoris*, the genus *rhea* has been found in the caverns of Brazil, and the *dinornis*, *apornis*, &c., have been met with in alluvial deposits so superficial as to lead to the belief that they belonged to the present period, having been exterminated, like the dodo, since the creation of man; the *gralla* are more abundant than the preceding orders in the oldest tertiary, and even extend into the cretaceous; the *palmipedes* are still earlier, and the genus *timoliornis* (Owen), coming near the albatross, has been found in the chalk of Europe; it is said that feathers and eggs have been obtained from the tertiary of Europe.

ORNITHORHYNCHUS (Gr. *ornis*, a bird, and *pyxos*, a beak), the name of a genus of implacental mammals of the order *monotremata*, which seem to form a connecting link between mammals and birds, and in some respects having affinities even with reptiles. A single species only is described, the *platypus anatinus* (Shaw), or *ornithorhynchus paradoxus* (Blumenb.), the duck-billed platypus of English writers, the water mole of the colonists, and the *mallangong* of the natives; it inhabits the fresh water streams of Australia and New Guinea. It is from 18 to 22 inches from the end of the jaws to the point of the tail, the latter being about 5 inches; the color above varies from ruddy to dark brown, and is whitish below; the jaws are enclosed in a horny sheath, very sensitive, like the bill of a duck, and have 2 horny teeth on each side above and below, flat, rootless, composed of perpendicular horny tubes; the snout is flat and broad, the lower jaw the narrowest and shortest and provided with lamellæ on the sides; the eyes small and brilliant; ears not apparent externally, with an aperture which can be opened or shut at will; the tongue consists of 2 parts, the posterior broad, flat, with soft papillæ and a free process bearing 2 pointed horny teeth, the anterior narrow and covered with upright points longest and sharpest toward the tip; the nostrils are at the end of the upper mandible; cheek pouches are present, and a bulb on the back of the tongue prevents the contents of the mouth from passing into the larynx; the fur is soft and thick, like that of the otter. The legs are short, and the feet 5-toed, webbed, and furnished with strong claws; the fore feet are the strongest, and their loose webs extend beyond

the claws; the hind legs are armed with a sharp, conical, bony spur, with a corneous investment, perforated for the passage of a duct communicating with a gland situated on the thigh; the tail is flat, broad, and beset with rigid hairs. As the name of the order imports, the alimentary, urinary, and reproductive organs open into a common cloaca, as in birds; mammary glands are present, which secrete milk for the nourishment of the young, which are born blind and naked; there are no prominent nipples, and the mammary openings are contained in slits in the integument; the beak in the young is short and flexible, adapted for sucking; M. Verreaux (*Revue zoologique*, 1848) states that the young, when they are able to swim, suck in the milk from the surface of the water into which it is emitted by the female. The shoulder bones are unlike those of other mammals, and are intermediate in arrangement between those of birds and reptiles, as stated in the article *MONOTREMATA*; in many points of the generative system, also, there are ornithic and reptilian affinities. For details on anatomical structure and on the habits, the reader is referred to the work of Meckel on this animal; the article "Monotremata," by Owen, in the *Cyclopædia of Anatomy and Physiology* (vol. iii., 1847); the "Philosophical Transactions" (1802, 1819, 1822, and 1834); "Transactions of the Zoological Society" (vol. i., 1835), and "Proceedings" of the same society for 1859. The extraordinary characters of this animal are such that, when it was first exhibited by Dr. Shaw, it was believed to be a manufactured monster, partly bird and partly mammal, like the half-monkey, half-fish creature which has been exhibited as a mermaid; and it was not until its anatomy was made out by Home, Owen, and Meckel that naturalists would admit it as a true animal. It burrows in the banks of streams, where it passes the day in sleep rolled up like a ball, coming out at dusk and during the night in search of food; it is an excellent swimmer and diver, and feeds upon worms, insects, and small aquatic animals, in the manner of a duck; it walks very well, and climbs trees with facility; the burrows, which have an opening below the water, are sometimes 20 or 30 feet in length, extending upward beyond the reach of inundations; in the highest and driest part is an enlarged cavity for the nest of themselves and young. It can remain under water only about 7 or 8 minutes at a time; it is cleanly in habit, and fond of warmth and dryness. The young in confinement are playful, and will eat rice and egg, soaked bread, and finely chopped meat; they are, however, rather delicate, and die very soon from want of food; when handled they make ineffectual attempts to bite, but do not use the spurs as weapons of defence or offence; their habits in a state of nature are not very well known. It is ascertained that they do not lay eggs, as was at first supposed, but are true mammals; the fluid secreted by

the femoral gland is not poisonous. Though skins of this animal are not uncommon in collections, its skeleton is very rare; they are rapidly disappearing, and no doubt will ere long be added to the extinct or decaying races, like the dodo, *dinornis*, Irish elk, and apteryx.

OROBIO, BALTASAR, called also ISAAC DE CASTRO, a Spanish physician and controversialist, born early in the 17th century, died in 1687. He was educated in the Jewish religion by his parents (who outwardly conformed to Catholicism), became distinguished in the scholastic philosophy, and was appointed professor of metaphysics in the university of Salamanca. Subsequently he studied medicine, and practised in Seville, where, being accused of Judaism, he was imprisoned and tortured by the inquisition, but persisted in professing himself a Christian. At the expiration of 8 years he was released, resided some time in Toulouse as professor of physics, and then went to Amsterdam, where he made a public profession of Judaism, was circumcised, and took the name of Isaac. In 1684 he published a treatise entitled *Certamen Philosophicum*, directed against the system of Spinoza, as well as against Breidenburg, who had attempted to refute Spinoza. But he is most celebrated for his controversy with Philip Limborch in regard to the relative merits of Christianity and Judaism. Orobio wrote 3 papers against the Christian religion, afterward printed by Limborch, in an account of the dispute, under the title *Amica Collatio cum Judæo*.

ORONTES, a river of Syria, whose name, according to Strabo, was originally Typhon, which was changed to Orontes because a man of that name built a bridge over it. It rises not far from Baalbec in Coele-Syria, flows toward the N. between the mountain ranges of Lebanon and Anti-Lebanon, and then turning to the W. into the country of Antioch, finally falls into the Mediterranean near lat. 36° N. The Orontes is now called Bahr-el-Asi, "the rebel river," according to Abulfeda, because it refuses to water the fields without the compulsion of water wheels; or according to Barker, "from its occasional violence and windings during a course of about 200 miles in a northerly direction, passing through Hems and Hamah, and finally discharging itself into the sea at Suweidiah near Antioch." The course between Antioch and the sea is remarkable for its great beauty.

OROSIUS, PAULUS, a Spanish presbyter, born about the end of the 4th century in Tarragona, died probably in Africa. After studying in his native country, he went to Africa about A. D. 414 to consult St. Augustine on several points of doctrine then under discussion by the sects of the Priscillianists and Origenists. Here he wrote his earliest work, entitled *Consultatio eise Commonitorium Orosii ad Augustinum de Errore Priscillianistarum et Origenistarum*, to which Augustine replied in the treatise *Contra Priscillianistas et Origenistas Liber ad*

Orosius. In 414 or 415 he set out for Palestine, avowedly to complete his studies under St. Jerome at Bethlehem, but really to counteract the influence of Pelagius. He soon won the confidence and affection of Jerome, who shortly after attacked the doctrines of Pelagius in an anonymous work. In 415 Orosius arraigned Pelagius for heresy before the tribunal of John, bishop of Jerusalem; but the authority of Augustine did not stand so high in the oriental as in the western church, and the accusers did not succeed in gaining their case either on the present occasion or in the appeal made to the council of Diospolis. Orosius himself, having been denounced by John as a blasphemer, wrote a work entitled *Liber Apologeticus de Arbitrii Libertate*, in which he defended himself and attacked the doctrines of Pelagius. The capture and sack of Rome by the barbarian converts to Christianity gave occasion to those who still adhered to the old faith to say that Christianity had been of more injury than service to mankind. Against this view Augustine had written his work *De Civitate Dei*; and at his instance Orosius composed a treatise entitled *Historiarum adversus Paganos Libri VII.* These annals extend from the creation of the world down to the year 417, and were received with great enthusiasm when they first appeared. For a long time they were highly esteemed, but the researches of modern scholars have proved that, with the exception of the concluding portions, they are utterly destitute of historical value. This work was translated into Anglo-Saxon by King Alfred, and of this translation there are 8 editions: one by Daines Barrington with an English version (8vo., London, 1773); another by B. Thorpe, with an English version (8vo., London, 1853; published with Pauli's "Life of Alfred the Great" in Bohn's "Antiquarian Library"); and another with an English version by Dr. Bosworth (London, 1855). The *editio princeps* of the history was published in Vienna (fol., 1471); but the only edition of any value is that of Havercamp (4to., Leyden, 1788). To this is appended an edition of the *Apologeticus*, which was first printed in Louvain in 1558. There are other writings which have been generally ascribed to Orosius, but as yet no edition of his complete works has been published.

ORPHAT. See **ARAFAT**.

ORPHEUS, the reputed author of the Orphic doctrines and mysteries, which first appeared in Greece about the 6th century B. C. He was the chief of a circle of poets, embracing also Linus, Musæus, and Eumolpus, to whom were attributed various theogonic and mystical hymns and poems, developing theological subjects, and inculcating religious conceptions different from those of Homer and Hesiod. An ante-Homeric antiquity was assigned to these apocryphal writings, and they were received by the Greeks as a sort of divine revelation. From the schools which propagat-

ed the Orphic doctrines a series of poems proceeded until about the Christian era, for all of which the same authorship was claimed. The whole literature is usually regarded as embodying a theosophical and mystical movement in the Greek religion, concerning the origin of which there is little certainty. The name of Orpheus does not appear in Homer or Hesiod. He is mentioned by Ibycus in the 6th century as the "renowned Orpheus;" by Pindar as son of Oëgrus, one of the Argonauts, and the father of songs; by Hellanicus as the ancestor of both Homer and Hesiod; by Æschylus as leading the trees after him to the sound of his lyre; by Eratosthenes as worshipping Apollo rather than Dionysus (Bacchus); by Euripides as related to the Muses, as charming by his song the rocks, trees, wild beasts, and infernal powers, as connected with the Bacchanalian orgies, as founder of the sacred mysteries, and as living amid the forests of Olympus; and by Aristophanes as one of the oldest poets and the teacher of religious initiations. Plato repeats most of the previous accounts of him, and gives an explanation of the story of his descent into Hades, according to which, since he had not ventured to die, but had contrived to enter their realm alive, and thus transcended the allotted condition of mortal men, the infernal gods showed him only a phantasm of his wife, and moreover caused his death at the hands of women. Though Plato quotes from the collection of Orphic writings, he evidently regarded them as spurious; but he seems not to have doubted the existence of Orpheus or the genuineness of his peculiar theogony. Aristotle, however, held that Orpheus was altogether a fictitious personage, and the works ascribed to him forgeries. Later accounts make him a Thracian bard in the era of the Argonauts, to whom Apollo gave a lyre, in the use of which he was instructed by the Muses, and who on account of the miraculous charm of his song was engaged as one of the Argonauts. On their expedition the power of his lyre held back the moving Symplegades, which threatened to crush the ship, lulled the Colchian dragon to sleep, and rendered other important services. On his return he applied himself to the civilization of the rude inhabitants of Thrace, was reputed to have visited Egypt, and according to the legends sought his deceased wife Eurydice in Hades, where the music of his lyre suspended the tortures of the damned, and won back his beloved on condition that he should not look round at her till she reached the upper world. He violated the condition, and saw her vanish from his view. In his despair he treated the Thracian Mænads with contempt, who avenged themselves by tearing him to pieces in their orgies. According to another legend, he perished by the thunderbolts of Zeus (Jupiter). The remnants of his body were gathered by the Muses, and buried at the foot of Olympus, where a nightingale sang above his tomb.—The earliest of the Orphic compositions are now usually

ascribed to Onomacritus, who lived at the court of Hipparchus, son of Pisistratus. About the same time the Orphici, or associations of the followers of Orpheus, transformed the Dionysiac worship, giving to it an ascetic and mystical rather than orgiastic character. This worship was further modified, and its influence on the Greek religion increased, by the union of Orphic and Pythagorean societies and doctrines. A decided pantheistic tendency marks the Orphic theology. It has a cosmogony entirely unlike that of the Homeric poems as well as a theory of immortality, founded on metempsychosis, which is deemed foreign to the genius of the Greek religion, and akin to oriental speculations. According to it, Chronos (time) was the first principle, from which proceeded Chaos and Æther. The former was an infinite and shapeless mass, which, in condensing under the influence of the latter, assumed an ovoid form, containing in its centre the cosmical germ. From this primordial germ, this vast mundane egg, sprang the golden-winged Eros or Phanes, the first manifestation of intelligence or light, who in union with Night created the heavens and the earth. Ericapæos was the creative word which gave birth to all the gods. The soul, at first diffused in the depths of matter, was brought to the surface, and all the elements were arranged and prepared for generation. Zeus had four predecessors, instead of one as in the Homeric theogony, and among the gods and goddesses proceeding from him Zagreus Dionysus was pre-eminent. Rejecting Hesiod's view of successive ages, each worse than the preceding, the Orphic poets cherished faith in a cessation of strife, a holy peace, and a state of the highest beatitude at the end of all things. This hope they rested upon the god Dionysus, who had passed through the greatest perils, had been once torn in pieces by the Titans and born again, yet was destined to succeed Zeus in the government of the world and to restore the golden age. From Dionysus was expected the liberation of souls, in fulfilment of the Orphic notion that souls are confined in the body as in a prison for punishment, and that they long for a higher state of existence, to which they pass by gradual purification and enlightenment. The Orphic poems show the gradual influx of Thracian, Phrygian, and Egyptian religious ceremonies and feelings, when secret voluntary combinations were formed for purposes of religious purification, bound together by mystical solemnities and vows of an ascetic character, and cherishing contemplations and habits strikingly in contrast with the simple, genial, and demonstrative worship of the Homeric Greeks. Thus the so called Orphic life, the regulations of the Orphic brotherhood, among other injunctions of abstinence, forbade animal food universally, and on occasions the use of woollen clothing. The religious and political fraternity of the Pythagoreans, after its banishment from the Italian cities, favored and manifested the same

tendency; and thus a new class of ideas and ceremonies, more or less directly of oriental origin, was introduced into the Greek worship. Yet this attempt at reform seems to have obtained currency chiefly among cultivated and speculative men. The Orphic writings increased in honor during the declining centuries of paganism, and by both the Christian and pagan Neo-Platonists of the 3d and 4th centuries were believed to be the most ancient and venerable summary of the Greek faith. They then received a large accession of forgeries by Christian philosophers, the genuineness of all of which was accepted even by modern scholars till a comparatively recent period. The apocryphal productions included under the title of *Orphica* are: a poem on the Argonautic expedition, in 1,884 hexameters; a collection of hymns in hexameters, evidently of Neo-Platonic origin; *Lithika*, better than either of the preceding, and treating the properties of stones and their uses in divination; and fragments, chiefly of the theogony, containing the only remains of the early Orphic literature. The best edition is that of Hermann (Leipsic, 1805).

ORPIMENT. See ARSENIC, vol. ii. p. 163.

ORB, JAMES LAWRENCE, an American statesman, born in Craytonville, Anderson district, S. C., May 12, 1822. He received a tolerable education, including the rudiments of Latin and Greek, but until his 18th year was obliged to employ a portion of his time behind the counter of his father, who was a country shopkeeper. In 1840 he entered the university of Virginia, where he was graduated in 1842. He studied law, and in 1848 was admitted to the bar, and commenced practice in Anderson, where he also established and for several years edited the "Anderson Gazette." In 1844 he was elected to the state legislature from the Pendleton district by a large majority, and was returned at the next election by an equally decisive vote. During his second term he spoke in opposition to a proposed nullification of the tariff act of 1842, and in favor of giving to the people at large the election of the electors of president and vice-president of the United States—a right then, as subsequently, exercised by the legislature of the state. Between 1845 and 1848 he devoted himself principally to his profession, and in the latter year he was elected to congress. From that time down to the close of the 35th congress, March 4, 1859, he was regularly reelected from his district without opposition. During the long debates to which the application of California for admission to the Union gave rise, he opposed the settlement of the questions at issue between the North and the South on the basis of the compromise measures proposed by Mr. Clay, urging that they were unjust to the South; that there was a latent fraud in the organization of Utah and New Mexico; that California was admitted with excessive territories, without regard to the rights, propertities, and decencies which had previously prevailed in the

admission of states, and without waiting for authority from congress to frame a constitution; and that the whole procedure was a scheme to defraud the South of all share in the territories. He accordingly voted against all the measures of the compromise bill, except that providing for the rendition of fugitive slaves. He was a member of the state convention which met in Charleston in May, 1851, to consider the propriety of withdrawing South Carolina from the Union in consequence of the alleged aggressions of the northern majority in congress, and of the passage of the compromise measures. He was one of the leaders of the small minority in this body who opposed secession on the ground of its inexpediency, and of the impolicy of taking so decided a step without the concurrence of other southern states. At the same time he fully admitted the right of a state to secede. The resolution against separate action by South Carolina, upon which the minority report was based, and which subsequently became the creed of the coöperation, as distinguished from the secession party, was introduced by him; and it was in a great measure owing to his efforts that the ordinance of secession failed of the two-third vote necessary to its passage. In the 33d congress he was appointed chairman of the committee on Indian affairs, and made an elaborate report on the proper means of civilizing the Indians, which in the case of some tribes was adopted with a considerable degree of success. During the same congress he supported the policy of non-intervention by congress on the subject of slavery in the territories, and voted for the repeal of the Missouri compromise, and the principles involved in the Kansas-Nebraska bill. In the 34th congress, which remained several months without a speaker, he was a prominent democratic candidate for that office, and during many successive ballots received the votes of his party, though without success. Upon the assembling of the 35th congress, however, he received the caucus nomination for the speakership, and was elected by the house on the first ballot. He discharged the duties of the office with ability, and during his occupancy of the speaker's chair his decisions were never overruled. A decided democrat in politics, he endeavored, though without success, to procure the regular representation of his state in the national conventions of the party, and was instrumental in selecting Charleston as the place of meeting of the nominating convention of 1860. He has also been at different times urged as a candidate for the offices of vice-president and president. After his retirement from congress he modified his belief in the efficacy of the democratic party to save the Union or even itself, and during the presidential canvass of 1860 he expressed himself in favor of a confederacy of the southern states, although still opposed to the separate secession of South Carolina from the Union. His views changed in this respect also after the election of Mr. Lincoln and as a member of the South

Carolina convention which met in Dec. 1860, he recorded his vote in favor of the immediate and separate secession of his state. He subsequently officiated as one of the 8 commissioners despatched by South Carolina to Washington to treat with the general government for the surrender of the U. S. forts in the harbor of Charleston, and to transact other business. He was also present in the capacity of commissioner from South Carolina at the secession convention of the state of Georgia, which met at Milledgeville, Jan. 16, 1861. Mr. Orr has been a busy legal practitioner, and has acquired a reputation as an orator before literary societies.

ORRERY, a machine representing the motions of the planetary bodies. Distinct names have been given to various modifications of it: the planetarium, which exhibits the orbital paths of the planets and their satellites; the tellurium, which shows the motions of the earth causing day and night, the seasons, and the variable length of the former as dependent upon the latter; the lunarium, which shows the motions of the moon; and the satellite machine, chiefly intended to represent the motions of Jupiter and his satellites. The ordinary orrery was invented by George Graham about 1700, and first patronized by the earl of Orrery. Steele, probably supposing the earl to be the first promoter if not the inventor of it, called it by his name. The contrivance is useful rather in aiding the conceptions than in elucidating truths; but it is mischievously faulty owing to the impracticability of representing in model any thing like the proportions subsisting among the planetary bodies. Sir John Herschel calls it a "very childish toy." The best orreries are expensive and complicated.

ORRIS ROOT, the dried rhizome of the white iris (*iris Florentina*, Linn.), a plant of the natural order *iridaceae*, native of southern Europe and of the islands of the Mediterranean, having broad, somewhat falcate leaves, which are shorter than the stem, large, showy, white flowers, the petals 2 inches long and 1 inch broad, reflexed at their edges, and somewhat plaited at the base. The rootstock has an aromatic odor and subacid taste, and is used in preparing dentifrices. When fresh it acts as a purgative, and has been employed as an expectorant in diseases of the chest, being at one time admitted into the British pharmacopœia. The rhizomes or rootstocks of the purple iris or flower de luce (*I. Germanica*, Linn.), which grows spontaneously on walls and in dry places in Europe, are also sometimes employed for the same purposes. The roots of many of the irids contain starch, and several are eaten in various parts of the world. (See *IRIS*.)

ORSINI, the name of a celebrated Italian family, conspicuous in the history of the middle ages, especially at Rome, where, in wealth and political importance, they rivalled the Colonnas. Their ancestors, who originally came from Spoleto, were distinguished in the Christian metropolis as early as the 1st half of the 12th

century. Giordano, for his services to the pope as a soldier, was promoted to a cardinalship in 1145, and a few years later, in the capacity of legate, sent to Conrad III. of Germany; while his nephew, Matteo, held the post of prefect of Rome. Toward the end of the 12th century, Orso ruled the city as its senator, while another member of the family, Celestine III., occupied the papal chair. Their power was increased by the marriage of Orso's son, Giovanni, with the heiress of the house of Gaetani; and of their two sons, the elder, Napoleone, became count of Tagliacozzo in the kingdom of Naples; the younger, Matteo, styled the Great, continuing in Rome, was, like his grandfather, elected senator, at the same time holding Anagni and several other large fiefs in the Campagna. One of Matteo's sons, Giovanni, became pope under the name of Nicholas III. in 1277, and endeavored to perpetuate the dignity of senator in his family, for whom he secured princely alliances. The Orsinis now reached the zenith of their fortune, and their quarrels with the Colonnas filled for years the annals of Rome. They were Guelphs, and generally found on the side of the pope, while their rivals adhered to the Ghibelline party. They disputed the ascendancy sword in hand, and the struggle raged through the whole of the 14th century, without decisive results, although Petrarch celebrated the triumph of the Colonnas. The castle of Bracciano, on the lake of that name, was the chief residence of the family, who possessed beside many strongholds in Rome and its vicinity. Pope Alexander VI., in the beginning of the 16th century, found it expedient to get rid of three of their number; thus Cardinal Orsini was poisoned by his order at Rome, while his son, Cesare Borgia, caused Francesco and Paolo to be treacherously seized and strangled at Sinigaglia.—The Roman branch of the family became gradually extinct; but the Neapolitan branch is still extant. Some of the early members of the latter entered the service of the house of Anjou, obtained high honors at the court, and became counts of Nola and dukes of Gravina in the 15th century. Pietro Francesco gave up his duchy to his brother Domenico, entered the church, and in 1724 became pope under the name of Benedict XIII. The family still hold the highest rank among Italian nobles. Their present head, Prince DOMENICO ORSINI, born in 1790, holds the rank of lieutenant-general, and, beside the title of duke of Gravina, bears the honorary appellations of assistant prince of the holy see and senator of Rome. He married, Feb. 6, 1828, Maria Luisa, daughter of the celebrated banker Torlonia, duke of Bracciano, who has borne him three daughters and one son, Filippo. The seat of their family is still at Rome in the Orsini palace, which stands on the ruins of the theatre of Marcellus, but their usual residence until the revolution of 1860 was at Naples in the Gravina palace.—A younger branch of the family has settled in Piedmont, and is now represented

by GIACOMO ORSINI, count of Rivalta and Orbasano, born in 1786.

ORSINI, FELICE, an Italian revolutionist, noted for his attempt upon the life of Napoleon III., born in Meldola, a village of the Papal States, in 1819, executed in Paris, March 18, 1858. The son of a conspirator, he early engaged in political plots, and when scarcely 20 years of age was sentenced to penal labor for life. Restored to liberty in 1846 in consequence of the amnesty declared by Pope Pius IX., he returned to his former associates and participated in various insurrectionary movements in central Italy. On the revolution of 1848 at Rome, he was elected a member of the constituent assembly, vested with extraordinary powers, and sent to Ancona and Ascoli, where he suppressed brigandage by such violent means as to cause his censure by a court of justice. He participated in the defence of Rome and Venice, figured as an agitator in Genoa and Modena, and in 1853 was transported to England by order of the Sardinian government. He lived there on intimate terms with Mazzini, and was employed by him on several revolutionary missions. In May, 1854, under the assumed name of Tito Celsi, he attempted an outbreak in Parma, but failed, and retired to Milan, concealing himself under the name of George Hernagh, and afterward visited Trieste, Vienna, and Hermannstadt. In the last named city he was arrested and taken to Italy, where he was closely confined in the fortress of Mantua. Escaping in 1856, he returned to England, where he delivered lectures and wrote a book entitled "The Austrian Dungeons in Italy," which had a large circulation. In 1857 he repaired to Paris for the purpose of assassinating Napoleon III., whom he considered the main obstacle to the progress of revolution. In his plot he had three associates named Pieri, Rubio, and Gomez. On the evening of Jan. 14, 1858, as the emperor and empress were approaching the grand opera, three bombs were thrown under their carriage and exploded, killing or wounding a large number of persons, though the intended victims escaped unhurt. Orsini and his accomplices were arrested, arraigned before a court of justice, and sentenced, Orsini, Pieri, and Rubio to capital punishment, and Gomez to hard labor for life. At the scaffold Orsini evinced the utmost calmness, his last words being: *Vive l'Italie! vive la France!* Pieri had been beheaded before him; and through the intercession of the empress Eugénie the life of Rubio was spared.

ORSINI, FULVIO, an Italian antiquary and philologist, born in Rome in 1529, died in 1600. The natural son of a knight of Malta who belonged to the princely family of Orsini, he was deserted by his father in his childhood; but, overcoming the difficulties of poverty, he became one of the most learned men of his time. Entering holy orders, he won the favor of Cardinal Farnese, who appointed him his librarian. Pope Gregory XIII. also befriended him, and

he was thus enabled to gather an invaluable collection of medals and antiques, which he bequeathed to his benefactor's nephew, Cardinal Odoardo Farnese. He published many works on philological and antiquarian subjects.

ORTHOGRAPHY. See LANGUAGE.

ORTHOPTERA, an order of insects, with chewing jaws, 2 rather thick and opaque upper wings, slightly overlapping on the back, and 2 larger thin plaited straight wings under these; they undergo partial transformation, and the larvæ and pupæ, though wingless, are active. It contains the 4 groups of runners (earwigs and cockroaches), graspers (*mantes* or soothsayers), walkers (spectres and walking leaves), and jumpers (crickets, grasshoppers, and locusts). The *mantes* are carnivorous, and the other groups are more or less destructive to vegetation and to household articles; some of the strangest insect forms occur in this order.

ORTOLAN, or more properly ORTULAN, a bunting of the genus *emberiza* (Linn.). The bill is small, acute, and conical, and the palate is furnished with a prominent bony knob; the wings are moderate, the tail lengthened and somewhat forked, with feathers rather lanceolate; tarsi as long as the middle toe. This well known bird (*E. hortulana*, Linn.) is about 6½ inches long; the head and neck are greenish gray with dusky spots; the throat, space around eye, and band from bill downward, yellow; upper parts reddish bay, each feather black in the middle; below bay red, tipped with gray; tail blackish; the female is smaller, with brown spots on the breast and fainter colors. Rare in England, it is very abundant in southern Europe, where great numbers are caught in snares in early autumn, and fattened for the table in constantly lighted rooms on oats, millet, and spiced bread, on which the flesh becomes very fat and of a high and delicious flavor; they are considered perfect when they attain the weight of 8 ounces. They are very abundant on the island of Cyprus, where they are pickled in casks with spice and vinegar, each cask containing 300 or 400 birds; in some years the number of casks exported has amounted to 400. In ancient Rome epicures used to pay enormous prices for these delicacies, and they are as much relished, though less dearly bought, by the modern nations of southern Europe; many are annually prepared for the tables of the rich. It is a handsome bird, and has a flute-like warble, but is more prized for the table than as a cage bird.

ORVET. See BLINDWORM.

ORYX. See ANTELOPE.

OSAGE, a central co. of Mo., bounded N. by the Missouri river and N. W. by the Osage, and intersected by the Gasconade; area estimated at 850 sq. m.; pop. in 1856, 6,493, of whom 271 were slaves. It has an uneven surface, and near the streams a fertile soil. The productions in 1850 were 301,883 bushels of Indian corn, 26,329 of wheat, 43,410 of oats, 13,244 lbs. of wool, and 79,409 of butter.

VOL. XII.—38

There were 3 churches, and 208 pupils attending public schools. Capital, Linn.

OSAGE ORANGE, the familiar name of a tree of the natural order of *urticacea*, growing wild in the south-western parts of the United States. It was called *Maclura aurantiaca* by Nuttall, in honor of the American geologist William Maclure. It was first found near a village of the Osage Indians, which fact, connected with the globular form and golden color of its fruit, originated its popular name. The Osage orange, also called bow wood and yellow wood, is a striking and beautiful lactescent tree, growing 80 or 40 feet high; its foliage is not unlike that of the orange tree, but more glossy and polished and of a bright green color. Its branches spread widely into a broad head; its flowers are dioecious, small, pale yellowish green; the barren are about 12 in number, borne in a very short, almost sessile, racemose panicle, without calyx; corolla 4-parted, stamens 4; the fertile closely aggregate upon an axis, forming a little ball with a very short peduncle; the corolla oblong, urceolar, 4-lobed at tip, including the ovary, which is terminated by a filiform, downy style, considerably exerted beyond the corolla; the ovary at length becomes a small, compressed, oval achenium with a blunt and unsymmetrical tip; on ripening the little ball assumes a large, globular, and compact form, about the size of a large orange, yellow when ripe and roughened on the outside, containing a mucilaginous fluid, insipid and uneatable. The sap of the young wood and leaves is milky, and contains a large proportion of caoutchouc; the color of the wood is a bright yellow; its grain is fine and elastic, on account of which property it is employed by the southern Indians for bows. The young branches, beset with sharp, straight thorns, have suggested the employment of the tree for making live hedges, which succeed admirably where the winters are not so severe as to kill the annual growth. Treated as a hedge plant, it has many excellent characters, being robust, vigorous, and long-lived, sending out a profusion of strong shoots, bearing the shears well, and giving a charming effect by the lustre of its leaves. In order to form a compact growth, two shearings in a season are found requisite. It is easily cultivated and propagated, and pieces of the root planted out in the nursery, with the tips just exposed above the earth, will readily grow; seeds procured from fertile trees may be sown in broad drills, a quart of seed producing at least 5,000 plants. Silkworms have been fed upon the foliage, but the practice did not prove entirely satisfactory. The bark affords a strong fibre of a flaxy character. In affinity the Osage orange is closely related to the *moracea*. (See MULBERRY.)

OSAGE RIVER. See MISSOURI, vol. ix. p. 588.

OSAGES, a tribe of North American Indians, belonging to the Sioux or Dacotah family. The name by which they were known to the

Algonquins (*oyasash*) signifies bone men; and the word Osage, of French origin, is a corruption of that name. They have from very early times been prominent in the south-west, and are physically of good stature and courage. The tribe is divided into two bands, the Little and Great Osages. The latter make their permanent encampments on the river Osage of Missouri. By treaty with the United States, dated Dec. 30, 1825, the tribe is located upon a tract lying between lat. 37° and 38° N., and long. 94° and 98° W., and watered by the Arkansas, Verdigris, and Neosho rivers. This tract contains 7,564,000 acres, of which probably 5,800,000 acres are cultivable. When it was surveyed, at the time of the treaty, the tribe numbered 5,500, and the land was an allowance of 1,018 acres for each person. The numbers returned to the Indian department, however, are not to be relied upon, as the chiefs enroll more than the tribe contains, with a view to swell their annuity receipts from the government. In 1837 the tribe was estimated to contain about 4,000. It is scarcely possible that it may at present consist of 3,000. They do not confine themselves to the boundaries of their territory, but range the whole country between the Arkansas and Missouri rivers. They are open plunderers of all defenceless white men that fall in their way. The chase is still ostensibly followed for subsistence by the whole tribe, their hunting grounds being in the Ozark mountains. The full-blooded Osages are indolent and intemperate, and manifest no disposition to engage in agricultural pursuits; but many half-breeds cultivate the soil. As many as 1,000 of the tribe have died in a year from destitution and disease; and during a prevalence of measles in 1852, 1,000 children died within a few weeks. A manual labor school for Osage children has been established under the supervision of the Rev. Father Schoenmakers.

OSAKA, one of the 5 great imperial cities of Japan, situated on the S. W. coast of Nippon, in the province of Setz, 33 m. from Miako, of which it is the port; lat. 34° 40' N., long. 135° 25' E.; pop. estimated at 400,000. In the 16th century it was for many years the capital of the empire. It is at the mouth of the Yedogawa, a river as wide as the Thames at London, across which there are many bridges of cedar wood. The city is protected by a large and strong stone castle on its E. side, and by two forts which separate it from its western suburbs. Its length is about 3 m. and its breadth somewhat less. Several canals, crossed by upward of 100 bridges, intersect the city. The streets are narrow and cross each other at right angles, and are kept very clean. The houses are built of wood, lime, and clay, and are two stories in height. It is the most commercial place in Japan, being singularly well situated for both inland and coasting trade. A thousand Japanese vessels are usually to be seen in its harbor, and its manufactures of cotton, iron, and saki are famous throughout

the empire. It is renowned as a seat of pleasure and dissipation, and the women are considered the handsomest in Japan.

OSCAR I. JOSEPH FRANÇOIS, king of Sweden and Norway, born in Paris, July 4, 1799, died in Stockholm, July 8, 1859. He was a son of the French general Bernadotte, afterward king of Sweden, his mother being Désirée Clary, the sister of Mme. Joseph Bonaparte, and received the name of Oscar from his godfather Gen. Bonaparte, then just returned from Egypt. He commenced his education at the Louis le Grand college, and was but 11 years old when his father was elected by the *Riksdag* of Sweden crown prince, as future successor of Charles XIII. After his removal to Stockholm in Nov. 1810, he was placed under the care of a Swedish governor, Count Aderstroem, and two preceptors, Tannstroem and Atterbom, the latter a distinguished poet. He soon acquired a perfect command of the Swedish language, and showed remarkable proficiency in literature, science, and the fine arts. He composed music, and some of his songs, hymns, and marches are still performed in Sweden. This, however, was but a diversion in the midst of more serious pursuits. He gave particular attention to politics, the military art, and other studies befitting his station, and in 1818 entered the university of Upsal, on which occasion he was elected its chancellor. He had previously renounced Roman Catholicism to embrace the national or Lutheran creed. He thoroughly imbued himself with Swedish sentiments, and held such views and opinions as promised a truly national administration. Notwithstanding the advice of his father, who, to strengthen or rather preserve his throne, was a pliant ally of Russia, he agreed with public opinion, now antagonistic to such a policy, and, without failing in filial respect, placed himself in an attitude of independence that made him extremely popular among his future subjects. On his accession to the throne, March 8, 1844, he adopted liberal measures, and caused bills to be presented to the *Riksdag* for the removal of the civil disabilities of the Jews, the freedom of manufactures and commerce, and parliamentary reform. This last project was ill received by the deputies of the nobility, and gave rise to troubles, during which King Oscar evinced great moral courage. His repeated attempts in the same direction from 1848 to 1854 were baffled by the domestic opposition, and suspended by events connected with the Crimean war. He was more successful in his exertions for religious reforms and the improvement of the social condition of women; but the most salutary law for which his kingdom was indebted to him is that of 1854, regulating the manufacture and trade of brandy, which retrieved Sweden from the brink of ruin, by the repression of drunkenness. He secured the good will of his Norwegian subjects, and avoided the dangers resulting from the union of the two kingdoms. His foreign policy was marked by prudence and firmness.

He tried to relieve his kingdom from the overwhelming influence of Russia. On the outbreak of the Crimean war, in concert with the king of Denmark, he issued a declaration of armed neutrality; and on Nov. 21, 1855, he concluded a defensive treaty with France and England, and was ready to commence hostilities, had not the two great western powers been disinclined to transform the eastern into a European war. His attitude toward Russia added to his popularity among the Swedes, and enhanced his character in the eyes of Europe. But constitutional disease, increased by the grief consequent upon the death of his second son Gustavus in 1852, and the anxiety resulting from the dangers through which he had to guide his kingdom, led him, on Sept. 25, 1857, to resign his authority into the hands of his eldest son, Charles, who took the title of regent. Oscar married in 1823 Joséphine Maximilienne Eugénie, daughter of Eugène Beauharnais, the son of the empress Josephine. Beside Charles XV., who succeeded him, he left two sons, Oscar Frederic, duke of Ostrogothia, and Augustus, duke of Dalecarlia, and two grandsons. His aged mother, a popular and accomplished woman, died at Stockholm, Dec. 17, 1860.

OSCEOLA (Seminole, *As-se-ho-lar*), a chief of the Seminole Indians, born in Florida about 1803, died at Fort Moultrie, near Charleston, Jan. 31, 1838. He was the son of an Indian trader, an Englishman named Powell, and his mother was the daughter of a chief. In 1835, while on a visit to Fort King, his wife, who was the daughter of a fugitive slave woman, was claimed as a slave by the owner of her mother, and was carried off as such. Osceola, in his anger making use of threatening expressions, was seized by order of Gen. Thompson, the U. S. Indian agent, and put in irons, but released after 6 days' imprisonment. Resolved upon vengeance, he lay in wait for Gen. Thompson for weeks and months, and at length finding him outside of the fort, Dec. 28, killed him and 4 other whites who were in company. This was the beginning of the second Seminole war. Osceola immediately took command of a band of Indians and fugitive slaves, who on the same day had surprised and massacred Major Dade, and a detachment of 110 U. S. soldiers. On Dec. 30, with 200 followers, he encountered Gen. Clinch and 600 Americans at the crossing of the Withlacoochee, and after a hard-fought action of upward of an hour was compelled to retreat. The Seminole chief was disabled by a wound early in the battle. Subsequently he fought several actions against the troops under Gen. Gaines, and on June 9, 1836, led a most daring and well conducted assault upon the fortified post at Micanopy, which was repulsed with difficulty by the garrison of 300 regular troops. On Aug. 12 he defeated the U. S. troops at Fort Doane. For upward of a year he conducted the struggle against superior forces with energy and skill; but on Oct. 28, 1837, while holding a

conference under a flag of truce with Gen. Jessup near St. Augustine, he was treacherously seized with a number of his followers and kept in confinement at Fort Moultrie till his death.

OSCILLATORY MOTION. See MECHANICS, vol. xi. p. 324.

OSCOLATI, GAETANO, an Italian naturalist and traveller, born in Veduggio, Lombardy, Nov. 29, 1808. He devoted himself from an early age to the study of the natural sciences, and in 1830 and 1831 visited Greece, Egypt, Asia Minor, and other provinces of Turkey. He embarked for South America in 1834, traversed the greater part of that continent, and returned to Europe by way of Cape Horn in 1836. In 1841 he undertook a journey to Arabia, Armenia, Persia, and the coast of Malabar in India, and in 1846 made a second visit to America. After passing hurriedly through Canada, the United States, the Antilles, and Venezuela, he went to Quito, and thence started on an expedition to the Napo, a tributary of the Amazon. His Indian guides abandoned him after several days' march, but he succeeded in reaching the Napo alone after a journey across a wide expanse of unsettled country and through trackless forests. During two weeks he had no food but palm leaves and a single kind of fruit. He returned to Europe in 1848, taking with him a rich collection of specimens and ethnographical memoranda; and he published at Milan, in 1854, an account of this excursion, entitled *Esplorazione delle regioni equatoriali lungo il Napo*.

OSGOOD, DAVID, D.D., an American Congregational clergyman, born in Andover, Mass., in Oct. 1747, died in Medford, Mass., Dec. 12, 1822. He was the son of a farmer at whose door James Otis was standing when struck dead by a flash of lightning. Till the age of 19 he labored upon the farm, and then began to study under the Rev. Mr. Emerson of Hollis, with such diligence that in 16 months he was prepared to enter Harvard college. He was graduated in 1771, studied theology for a year in Cambridge, and was ordained Sept. 14, 1774. He settled in Medford, where he continued as minister for nearly 50 years. He became in time a distinguished preacher, especially on political topics. He was a zealous federalist, and one of his sermons in 1794, occasioned by Citizen Genet's appeal to the people against the government, attracted great attention, and when published passed rapidly through several editions. His most celebrated discourse of this nature was an election sermon preached in 1809. He was a thorough Calvinist in opinion, and had little sympathy with Unitarian theology, though most of his intimate associates were Unitarians. The Rev. Dr. Francis says of him: "On the whole, he was a truly good and great man; an earnest seeker, and a fearless preacher of God's truth; of a robust, manly, vigorous mind, and of a heart full of unceremonious frankness, but by no means destitute of gentle

and kind affections." A volume of sermons by Dr. Osgood was published after his death (Boston, 1824).

OSGOOD, FRANCES SARGENT, an American poetess, born in Boston about 1812, died in New York, May 12, 1850. She was the daughter of Mr. Locke, a merchant of Boston. Early attracting the notice of Mrs. Lydia Maria Child, she contributed to a "Juvenile Miscellany," published by her, a number of poems under the signature of Florence. In 1835 she was married to Mr. S. S. Osgood, a painter, with whom she went to London, and there became known by her contributions to the magazines, by a miniature volume entitled "The Oasket of Fate," and by a collection of her poems entitled "A Wreath of Wild Flowers from New England" (8vo., 1839). Among these was a drama in three acts, entitled "Elfrida," which so interested James Sheridan Knowles, that at his request she wrote for the stage a play entitled "The Happy Release, or the Triumphs of Love." Although accepted, it was never performed. She returned to Boston in 1840, and afterward removed to New York, where she remained the rest of her life, contributing both in prose and poetry to the magazines. While there she edited, beside other works, "The Poetry of Flowers, and Flowers of Poetry" (New York, 1841), and "The Floral Offering" (4to., Philadelphia, 1847), both of which were illustrated gift books. An edition of her poetical works was issued in 1846, and a complete collection in 1850.

OSGOOD, SAMUEL, D.D., an American clergyman and author, born in Charlestown, Mass., Aug. 30, 1812. He was graduated at Harvard college in 1832, and at the Cambridge divinity school in 1835. After two years spent in travelling and preaching, he was ordained in 1837 over the Unitarian church in Nashua, N. H. He was called thence at the close of 1841 to the Westminster church, Providence, R. I., and in 1849 to the church of the Messiah, New York, where he still remains. He received the degree of D.D. from Harvard college in 1857. Dr. Osgood has been a voluminous writer. His first publications were translations from Olshausen and De Wette, "The History of the Passion" (Boston, 1839), and "Human Life" (Boston, 1842). His original works are: "Studies in Christian Biography" (New York, 1851); "The Hearthstone" (New York, 1854); "God with Men" (Boston, 1854); "Milestones in our Life Journey" (New York, 1855); and "Student Life" (New York, 1860). He was an editor of the "Western Messenger," Louisville, Ky., in 1836 and 1837, and of the "Christian Inquirer," in New York, from 1850 to 1854. He has contributed largely to the "Christian Examiner," and published some articles in the "North American Review," the "Bibliotheca Sacra," and the leading monthly magazines. His printed sermons, speeches, and orations are numerous, the most conspicuous among them

being his discourse at Meadville theological school on "The Coming Church and its Clergy" (1858), and his oration before the alumni of Harvard, at President Felton's inauguration in 1860. He has been active in literary and educational interests in New York and New England, and has been for some years domestic corresponding secretary of the New York historical society. His theological position is more with what is now called the "Broad Church," than either with the old school Unitarian, or the new school of rationalists. He is much devoted to the improvement of the young, and especially in attaching them to a genial church life.

OSHKI, ABRAHAM. See ABRAHAM OSHKI.

OSHKOSH, the capital of Winnebago co., Wis., situated on both sides of the Neenah or Fox river, at its entrance into Lake Winnebago, 90 m. N. N. E. from Madison; pop. in 1857, 8,041. The two portions of the town are connected by 3 bridges. Both the river and lake are navigable for steamboats, and there is an extensive trade in lumber. It contains several saw mills, 2 planing mills, an iron foundry, and 3 churches.

OSHMONEYN, ESHMOONEIN, or ACHMOU-NEYN, a village of Egypt, on the left bank of the Nile, in lat. 27° 50' N.; pop. about 4,000. It occupies the site of the ancient Hermopolis Magna, which was the capital under the Greek rulers of a nome of Middle Egypt, or, according to Pliny and some other authorities, of Upper Egypt. It ranked second in importance to Thebes, and was famous for the worship of the divinities Typhon and Thoth. The former was represented by a hippopotamus on which sat a hawk fighting with a serpent. The latter, whose symbols were the ibis and the cynocephalus, was the principal deity of the place, and his name and emblems were introduced more frequently than those of any other god into the architectural designs. He was regarded as identical with Hermes or Mercury, and hence the Greeks gave the name of Hermopolis to the city, whose original appellation seems to have been Shmoun. A part of the beautiful portico of the temple of Thoth was standing during the present century; but being built of calcareous stone, the Turks destroyed it and burned it for lime. The pasha has also established a powder mill in the vicinity, and a number of workmen are employed in extracting nitre from the mounds which mark the site of the ancient city. To the westward is the ancient burial place of Hermopolis, where numerous ibis and cynocephalus mummies have been found.

OSIANDER, ANDREAS, often called by his German name of ROSEMANN or HOSSMANN, a Lutheran divine, born in Gunzenhausen, Franconia, Dec. 19, 1498, died Oct. 17, 1552. He studied amid much privation at Leipsic, Altenburg, and Ingolstadt, and was remarkable for his knowledge of the ancient languages, especially of Hebrew, and also of mathematics and

medicine. Afterward he became teacher of Hebrew in the Augustinian convent of Nuremberg, and in 1522 pastor of a church in that city, which position he held for 27 years. He joined Luther's party immediately after the attack on indulgences, and took a prominent part in the theological controversies of the period. He participated in the conference in 1529 at Marburg between the Swiss and Lutheran divines in regard to the doctrine of the real presence, and was present at Augsburg in 1530. On the promulgation of the Augsburg *Interim* in 1548 he left Nuremberg, but was invited by Albert, duke of Brandenburg, to become pastor and professor of theology in the university of Königsberg. He had never entirely agreed with Luther's views; and he now propagated opinions concerning penitence, the divine image in man, the two natures of Christ, and justification, which were combated by Melancthon and his colleagues, and led to a warm controversy, which continued for years after his death, ending in the execution of his son-in-law and partisan Funck and two of his friends for sedition, treason, and promoting the false doctrines of Osiander, with the formal condemnation of their heresies (1566). Osiander was a man of vast learning, eloquent, but eccentric and arrogant, and very violent against his opponents. He published works on the "Harmony of the Gospels," on the "Last Times and the End of the World," on "Prohibited Marriages," &c.

OSIER. See BASKET MAKING.

OSIRIS, one of the three deities to whom supreme honor was paid in all the districts of ancient Egypt. The name is variously rendered "lord of the earth," "many-eyed," and "power energetic and beneficent." In the mythological legend Osiris is represented as the originator of human civilization, and as engaged subsequently to his philanthropic services in a terrible contest with Typhon or Evil. Typhon prevails; Osiris is slain, and his dead body is fitted into a chest, thrown into the Nile, and swept out to sea. Isis, the consort of Osiris, learns of his death, and ransacks the world in search of his body. She finds it, but it is unrelentingly mutilated by Typhon. Then Osiris descends into the infernal regions, and has a later and different existence under the name of Serapis. Typhon is eventually slain by Horus, the son of Isis. This myth has been pronounced astronomical, and Osiris thought to personify the sun. But the Egyptians had, in addition to the worship of Osiris, a distinct sun worship, and others therefore have argued that Osiris was a personification of the Nile. Both interpretations appear too narrow. The existence of Osiris is partitive, and only complete conjointly with that of Isis. They together are the one universal god-power for good, in nature or elsewhere, but more directly because more apparently in nature. Isis was the passive element, or prolific power—terrestrial nature in general; in a more confined

sense, the soil of Egypt. Osiris was whatever acts upon passive nature for the good of man; the active energy of life; the beneficent or generative influence of the elements wherever exhibited. Hence he was at times, in a sense of fecundation, either the sun or the Nile, as both made Egypt fruitful. And, as the active power in nature is exercised intermittently, Osiris is continually overcome by Typhon, the disorderly, or evil, irregularity, and anarchy, and driven out of existence; but he has left a power in Isis that shall prevail in turn, and overcome the conqueror, who triumphs only for a time.

OSKALOOSA, the capital of Mahaska co., Iowa, situated between the Des Moines and Skunk rivers, about 6 m. from the former, and 68 m. S. W. from Iowa City; pop. in 1860, 2,475. It was laid out in 1844, and is in the midst of a healthful and fertile country, abounding in fine timber. It contains 2 steam mills, a state normal school, and several churches.

OSMAN. See OTHMAN.

OSMIUM, a metal discovered in 1803 by Tennant, and named in reference to the acrid odor of its oxide from the Greek *οσμη*, smell. Its symbol is Os; chemical equivalent 99.41; specific gravity 10. It is obtained in thin flexible plates, of bluish gray color, which may be ground to powder in a mortar, from the native alloys of osmium and iridium that constitute the mineral species iridosmine, and are found with platinum. Various processes are described in chemical books for separating it, by one of which by the treatment of osmic acid it is obtained in a pulverulent form. In this condition it takes fire when heated in the open air, and may be dissolved by strong nitric acid or aqua regia, by which it is converted into osmic acid (OsO_4). After ignition it is no longer soluble in acid, and is neither volatile nor fusible. Four other compounds with oxygen are described. The metal presents more analogy with arsenic and antimony than with the noble metals; it is of no use in the arts.

OSNABRÜCK (in English generally Osnaburg), a S. W. *Landdrostei* or province of Hanover, divided into the principality of Osnabrück, the lower county of Lingen, the circles of Meppen and Emsbühren, and the county of Bentheim; area, 2,411 sq. m.; pop. in 1858, 258,797, of whom about 144,000 were Roman Catholics. The country belongs for the most part to the plain of N. Germany, and is hilly only in the S. portion. In the level country the soil is generally sandy. The principal products are hemp, flax, and live stock, especially swine. The manufactures are principally woollen stockings and linen.—Osnabrück until 1802 was a bishopric, having been founded by Charlemagne. By the terms of the peace of Westphalia it was agreed that it should be alternately governed by a Roman Catholic and a Protestant bishop. The last bishop, Frederic of York, ceded the country to Hanover. It afterward became part of the kingdom of West-

phalia, then of the French empire, and after the fall of Napoleon reverted to Hanover. The inhabitants are of Saxon descent. The present diocese of Osnabrück embraces the entire province and East Friesland, and is subject to the bishop of Hildesheim.—OSNABRÜCK, the capital, is situated in a wide valley on the river Hase; pop. about 14,000. The most noteworthy public buildings are the cathedral, a Byzantine building of the 12th century, the churches of St. Mary, St. Catharine, and St. John, the palace built in 1663, and the town hall, in which the concluding conferences on the peace of Westphalia took place in 1648. The manufactures, which are important, consist of woollens, leather, linens, and above all, tobacco and cigars.

OSORIO, HIERONYMO, a Portuguese author, born in Lisbon in 1506, died in 1580. He was of noble birth, and received an excellent education, studying languages at Salamanca, philosophy at Paris, and theology at Bologna. He chose the ecclesiastical profession, and on his return to Portugal was made archdeacon of Evora, and ultimately bishop of Sylves. At the request of Cardinal Henry he wrote a history of the reign of King Emanuel. He also wrote a work called *De Gloria Libri V.*, which, on account of its elegant and pure Latinity, D'Alembert affirmed to be a production of Cicero's; and he was often styled the Cicero of Portugal; but Lord Bacon says "his vein was weak and material." A complete collection of his works in 4 vols. was published in Rome in 1592. His more popular writings have been translated into English, French, and Portuguese.

OSPREY. See FISH HAWK.

OSSIAN, a traditional Scottish hero and bard, who is supposed to have flourished in the 2d or 3d century of the Christian era, and whose compositions in the Celtic language were for many ages preserved among the Scottish and Irish peasantry. He is said to have survived his race, and like Homer to have died blind. His father Fingal was one of the most famous of the Celtic legendary heroes; but both father and son are now generally regarded as mythical personages, although a temporary importance was given to the former in the last century by the publication of Macpherson's alleged translations from "Fingal," "Temora," and other poems by Ossian. (See MACPHERSON, JAMES.)

OSSIFICATION. See BONE, and CARTILAGE.

OSSOLI, MARGARET FULLER, an American authoress, born in that part of Cambridge, Mass., which is called Cambridgeport, May 23, 1810, died by shipwreck on Fire island beach, off the shore of Long island, July 16, 1850. She was the eldest child of Timothy Fuller, a lawyer and politician, who was a representative in congress from 1817 to 1825. He conducted the early education of his daughter himself. Under his tuition she was subjected to a severe discipline, which made her

"a youthful prodigy by day, and by night a victim of spectral illusions, nightmare, and somnambulism." At 6 years of age she read Latin; at 8 she began to pore over Shakespeare, Cervantes, and Molière; and her lonely studies had induced a habit of melancholy and reserve before she was sent away to school at Groton, Mass. There she was remarkable for her capacity and freaks of passion, and for eccentricities which, as she records, received a salutary chastisement from her schoolmates. While a school girl, "she was considered," says William Henry Channing, "a prodigy of talent and accomplishment; but a sad feeling prevailed that she had been overtasked by her father, who wished to train her like a boy, and that she was paying the penalty for undue application in nearsightedness, awkward manners, extravagant tendencies of thought, and a pedantic style of talk." She returned home from school at the age of 15, and began an extended course of self-culture. Among the authors whom she read within a few years were Ariosto, Helvetius, Sismondi, Sir Thomas Brown, Mme. de Staël, Bacon, Epictetus, Racine, Locke, Byron, Sir William Temple, Rousseau, and many others. Conversation was already her most decided gift, and she attracted a circle of companions, who were wont to meet at their several residences for the discussion of opinions and sentiments. "Oh, for my dear old Greeks," she wrote, "who talked of every thing—not to shine as in the Parisian saloons, but to learn, to teach, to vent the heart, to clear the mind!" She began to study German in 1832, and within a year had read the principal works of Goethe, Schiller, Tieck, Körner, and Novalis. Her journals and letters soon after mention Lessing, Plato, Tennemann, Ugo Foscolo, and the evidences of the Christian religion, as engaging her attention; and she also projected the composition of several dramas. The family removed to Groton in 1833; her father died two years afterward, leaving little property; and she renounced a plan of accompanying Harriet Martineau on her return to England, to teach Latin and the modern languages in Boston to private classes and in Mr. Alcott's school. In 1837 she accepted a more liberal offer as principal of a school in Providence, reluctantly giving up a project of preparing the life of Goethe for Ripley's "Specimens of Foreign Literature." Emerson, with whom she had now become acquainted, thought "there was something a little pagan about her." He thus describes her personal appearance at this period: "She was rather under the middle height; her complexion was fair, with strong fair hair. She was then, as always, carefully and becomingly dressed, and of lady-like self-possession. For the rest, her appearance had nothing prepossessing. Her extreme plainness, a trick of incessantly opening and shutting her eyelids, the nasal tone of her voice, all repelled; and I said to myself: We shall never get far. It is to be said, that Margaret made a disagree-

able first impression on most persons, including those who became afterward her best friends, to such an extreme that they did not wish to be in the same room with her. This was partly the effect of her manners, which expressed an overweening sense of power and slight esteem of others, and partly the prejudice of her fame. She had a dangerous reputation for satire in addition to her great scholarship. The men thought she carried too many guns, and the women did not like one who despised them." On better acquaintance he found her more agreeable. "She was an active, inspiring companion and correspondent, and all the art, the thought, and the nobleness in New England seemed at that moment related to her and she to it. She was everywhere a welcome guest. The houses of her friends in town and country were open to her, and every hospitable attention eagerly offered. Her arrival was a holiday, and so was her abode. She stayed a few days, often a week, more seldom a month, and all tasks that could be suspended were put aside to catch the favorable hour, in walking, riding, or boating, to talk with this joyful guest, who brought wit, anecdotes, love stories, tragedies, oracles with her." In 1839 Miss Fuller went to reside at Jamaica Plain in the vicinity of Boston, and in 1840 became editor of the "Dial," a quarterly journal which she conducted for two years, aided by R. W. Emerson, George Ripley, and others. For this work she wrote many articles, of which those on Goethe and Beethoven attracted most attention. She also wrote for it "The Great Lawsuit," an eloquent expression of discontent at the social position of woman, which was afterward expanded into a volume and published under the title of "Woman in the 19th Century." In 1841 she translated and published the "Letters of Günderode and Bettina," and in 1843 made a journey to Michigan and Lake Superior, and published a narrative of it called "Summer on the Lakes." In Nov. 1839, she began with a class of 25 ladies of Boston and its vicinity a series of weekly meetings for conversation on literary and æsthetic topics, at which she was the principal talker, and which continued till 1844. In December of the latter year, at the invitation of Mr. Horace Greeley, she removed to New York and became an inmate of his house and a contributor to the "Tribune," principally of reviews, which with other articles from her pen were subsequently collected and published under the title of "Papers on Art and Literature" (New York, 1846). In the spring of 1846 she visited Europe, and after travelling extensively in Great Britain and on the continent, arrived at Rome in May, 1847, where in December she was married to a Roman nobleman, the marquis Giovanni Angelo Ossoli. She was in Rome during the revolution of 1848, and during the siege of the city by the French in 1849 was, at the request of her friend Mazzini, appointed directress of one of the hospitals for the wound-

ed. Subsequently she wrote a history of the revolution and siege, the MS. of which was lost at the time of her death. In May, 1850, she embarked at Leghorn in the ship *Elizabeth* for New York, with her husband and infant son, both of whom perished with her in the wreck of the vessel in the vicinity of its intended port.—See "Memoirs of Margaret Fuller Ossoli," by R. W. Emerson, W. H. Channing, and J. F. Clarke (Boston, 1852).

OSSUNA, PEDRO TELLEZ Y GIRON, duke of, a Spanish soldier and statesman, born in Valladolid in 1579, died in 1624. He was educated at the university of Salamanca, and was early introduced to the court, where his satirical disposition brought upon him the displeasure of Philip II. He first retired to Saragossa, where he aided in the escape of Antonio Perez, the disgraced secretary of the king, then went to France and afterward to Portugal, and did not return home until after Philip's death. For his freedom of speech he was again exiled, and repaired to Flanders, where he fought at the head of a regiment which he had raised at his own expense. Through the influence of the duke of Lerma he was recalled in 1607. He advised the duke of Lerma to conclude the truce of 1609 with the Dutch, and strenuously opposed the expulsion of the Moriscos from Spain. In consequence of this and some jesting remarks about a miracle, he was accused of infidelity and tried before the inquisition, but was acquitted, and in 1611 was appointed viceroy of Sicily. In 1616 he was sent to Naples in the same capacity. Here, as well as in Sicily, his exertions were directed to improving the condition of the country, which rendered him extremely popular with the middle and lower classes, but exposed him to the hatred of the nobles, while his refusal to establish the inquisition within the limits of his government drew upon him the enmity of the clergy. Conscious perhaps that this powerful opposition must soon ruin him at court, he indulged in wild and ambitious schemes, which, it is suspected, tended to the establishment of an independent sovereignty in southern Italy. To this end, and in order to mislead the Spanish government, he concocted the celebrated conspiracy against Venice, the apparent aim of which was the subjection of that republic to Spain, but which was in reality only the first step toward the creation of a kingdom for himself. As no formal charge could be brought against him, he was merely recalled, and his return to Madrid in 1620 was almost a triumph. But on the accession of Philip IV. he was arrested and subjected to a rigorous inquest, which lasted 8 years. The results of this trial were kept secret. Ossuna, however, being probably afraid of its consequences, put an end to his life by poison, which, it is reported, was secretly brought to him by his wife, in the castle of Alameda, where he was confined. His son Juan inherited his title and estate, and became viceroy of Palermo.

OSTADE, ADRIAN VAN, a Dutch painter, born in Lübeck in 1610, died in Amsterdam in 1685. He studied at Haarlem under Frank Hals, and is said also to have been a pupil of Rembrandt. Ostade's pictures generally represent the interiors of ale houses, farm houses, or kitchens, with Dutch boors carousing, and rural fairs or sports, in which the vulgarity and grotesqueness of the subject are redeemed by the manner of its treatment. When, in 1662, a French army approached Haarlem, he became alarmed and sold his pictures with a view of returning to Germany. Stopping on his way at Amsterdam, he was persuaded to change his resolution and to take up his residence in that city, where he remained until his death. His pictures, which are generally of cabinet size, are now comparatively scarce, and the best have increased in value six or seven fold within the last 50 years, those selling for £200 or £300 at the commencement of the century, now bringing upward of £1,400. Ostade also produced a number of etchings from his own designs.—**ISAAK VAN**, brother of the preceding, born in Lübeck in 1617, died about 1654. He received his first instructions from his brother, in whose style his earliest pictures are painted, although much inferior in color and execution. Subsequently he adopted a manner of his own, in which he proved himself an original master, and, according to Dr. Waagen, "by no means inferior to his brother." His subjects comprise travellers halting at inns, views of Dutch villages, winter pieces, and frozen canals covered with skaters. His pictures are not numerous, but those executed in his last manner have increased in value in a remarkable degree. Some of his finest works are contained in the collections of Great Britain.

OSTEN-SACKEN, DMITRI, count of, a Russian general, born in 1790. He entered the army in 1805, distinguished himself in the battles of Eylau and Friedland in 1807, and in the campaigns of 1812-'14, was promoted to the rank of major-general and made commandant of a brigade of hussars in 1825, and, accompanying Gen. Paskevitch to the Caucasus as chief of the staff, took part in the sieges of Akhalkalaki and Kars, and commanded the left wing of the Russian army at the battle of the Aras. Sent afterward into Poland, he relieved Diebitsch, who was hard pressed by the insurgents, contributed to the victory of Ostrolenka in May, 1831, and was present at the taking of Warsaw in September. In 1848 he was made general of cavalry, and in 1850 received the command of a corps of infantry. He was military commander of Odessa when that city was bombarded by the allies in April and May, 1854, received from the czar the most flattering marks of esteem for his defence on that occasion, and being subsequently sent to the Crimea was charged with the defence of the S. part of Sebastopol during the siege. He is now a member of the imperial council, and holds the rank of aide-de-camp general.

OSTEND, a seaport town of Belgium, in the province of West Flanders, on the North sea, 88 m. W. from Brussels, in lat. 51° 14' N., long. 2° 55' E.; pop. about 15,000. It stands upon low ground nearly surrounded by water, and is well built and clean. The *digue*, a sea wall 40 feet high, extends between the sea and the town for about $\frac{1}{2}$ m. The town is connected by canals with the central parts of Belgium, by railways with all parts of Europe, and by steam packets and submarine telegraph with England, being the principal landing place for travellers from England to Germany. The harbor is large, but access is difficult on account of the bar. The town has a citadel and walls with 4 gates. The cathedral and 3 churches and a large sea bathing establishment are the principal buildings.—Ostend was destroyed by the sea in 1334, and for some time afterward the present place was only a fishing village. It was enclosed with walls by Philip the Good of Burgundy, and fortified in 1583 by the prince of Orange. The Spaniards took it from the Dutch, after a siege of 8 years, in 1604; in the war of the Spanish succession the allies captured it in 1706; and in 1715 it was ceded by Holland to Charles VI. of Austria. It was taken in 1745 by the French, and restored in 1748; and again taken by the French in 1794 and held until the peace of 1814, the English having made an unsuccessful attempt to capture it in 1798. Messrs. Buchanan, Mason, and Soulé, three American envoys in Europe, met in Ostend in Oct. 1854, to deliberate on the acquisition of Cuba by the United States.

OSTEOLOGY. See **ANATOMY**, and **BONE**.

OSTERWALD, JEAN FRÉDÉRIC, a Swiss Protestant clergyman, born in Neuchâtel, Nov. 25, 1663, died there, April 14, 1747. On the completion of his studies he was appointed pastor of the Reformed church in Neuchâtel, which office he held during the rest of his life. He published an edition of the Bible in French, with explanatory heads to the books and chapters; *Abrégé de l'histoire de la Bible*; *Traité des sources de corruption parmi les Chrétiens*; *Traité contre l'impureté*; a catechism still popular among French Protestants; *Ethica Christiana*, &c. Osterwald, J. A. Turretin of Geneva, and Samuel Werenfels of Basel, were called the "triumvirate of Swiss divines," on account of their efforts toward the revival of religion in Switzerland.

OSTIA, a city of Latium, situated at the mouth of the Tiber, on the left bank of the southern arm of that river, 16 m. from Rome by the Via Ostiensis. It was founded by Ancus Marcius, who established there salt works by which the district around was supplied. It evidently grew with the growth of Rome, for, though not mentioned again until the 2d Punic war, it had become then a port and naval station of great importance, and of such vital consequence in its relation to Rome, that it was one of the two colonies allowed in 207 B. C. an exemption from military service. During the civil

war between Sylla and Marius, it was taken and plundered by the latter in 87 B. C.; but recovering from this attack, it so increased in importance that it became the residence of one of the 4 *quaestors* of Italy, with the title of *quaestor Ostientis*. But the deposition constantly made by the Tiber gradually filled up its port, and the difficulty of furnishing the city with grain finally induced the emperor Claudius to construct an artificial harbor on the right bank of the river 2 m. W. of Ostia. This new basin was called *Portus Augusti*, and was enlarged by Trajan, who added an inner basin, called from him *Portus Trajani*. The city of *Portus*, which sprang up about the new harbor, did not however cause the decline of Ostia, which was improved and adorned by succeeding emperors, particularly Hadrian and Septimius Severus. But, unprotected by walls, its defenceless condition hastened its decay during the later ages of the empire, so that in A. D. 827 it is described as being entirely in ruins. After the decline of *Portus*, the modern Ostia, about half a mile from the site of the ancient, rose into some importance, and became the landing place for travellers. This is now a miserable town possessing a small cathedral, a bishop's palace, and a few dwellings, and inhabited by about 200 persons, chiefly engaged in the manufacture of salt. The ruins of the ancient city are extensive, but so dilapidated as to be uninteresting. Although originally founded on the sea, it is now 3 m. distant, the intervening land having been formed by the alluvial deposits of the Tiber.

OSTRACION. See *TRUNK FISH*.

OSTRACISM (Gr. *οστρακισμός*, a tile or shell), an Athenian custom, employed in banishing from the state for a limited period any person deemed dangerous to the republic. The institution is supposed to have originated with Clisthenes after the expulsion of the Pisistratidae. Aristotle gives this explanation of its object: "Democratical states used to ostracize, and remove from the city for a definite time, those who appeared to be preëminent above their fellow citizens, by reason of their wealth, the number of their friends, or any other means of influence." Plutarch calls it a good-natured way of allaying envy by the humiliation of superior dignity and power; and ostracism is ably defended by Mr. Grote in his "History of Greece," who regards it as a wise measure devised by Clisthenes for removing quietly from the state a powerful party leader, before he could carry out any plot against the government. At first the banishment was for 10 years, but it was afterward reduced to 5. It involved no dishonor, nor any loss of property. The senate and public assembly determined whether ostracism was advisable; a day was then appointed, and a space in the agora enclosed, having 10 entrances for the 10 tribes, through which the citizens passed, each depositing in a prepared receptacle an oyster shell or potsherd (whence the custom was sometimes called the "earthen-

ware scourge"), inscribed with the name of the person whom he wished banished. The archons counted the votes, and if there were 6,000 votes against any one person, that person withdrew from the city within 10 days; otherwise he remained. Among the distinguished men against whom this sentence was pronounced were Aristides, Themistocles, Cimon, and Alcibiades. The last occasion on which it was employed was about 416 B. C. It existed in several other states, as Argos, Miletus, and Megara.

OSTRICH, the type of a group of terrestrial rasorial birds, with the cassowary, emu, kiwi-kiwi (*apteryx*), *dinornis* and its extinct congeners, constituting the family *struthionidae*, all which, excepting the ostrich, have been previously described. The family is readily distinguished by the massive body, elongated robust tarsi, and rudimentary wings. The genus *struthio* (Linn.) has a broad and depressed bill, with flattened culmen and strong rounded tip, the upper mandible overlapping the under; the oval nostrils are in a broad, membranous groove, near the middle of the bill; the wings are short and imperfect, with long, bending, and soft plumes; the tail moderate, composed of curved pendent feathers; tarsi very long and robust, covered with hexagonal scales, transverse in front near the toes; toes 2, short and strong, connected at the base by membrane, the outer short and much padded, and the other larger, with a stout, broad, flat nail. The only species is the African ostrich (*S. camelus*, Linn.), the largest of present birds, and excelled in former geological epochs only by some species of *dinornis* and *palaepteryx*; it stands 7 or 8 feet high, and weighs from 80 to 100 lbs. The skeleton is much as in other birds, except that the bones of the wings are rudimentary, the sternum flat and without keel, the pubic arch united in front, and the bones almost entirely destitute of air cells. The males are of a more or less black color, except the loose feathers of the wings and tail, which are white; the female is dark brownish gray, as also are the half-grown males. The head and neck are nearly naked, and the plumage generally is very loose, admirably suited for the climate, protecting from the sun's heat and at the same time allowing perfect ventilation; the quills of the wings and tail are remarkable for the length of the barbs, which, though having barbules, remain separate from each other; it is for these long white feathers of the wings and tail that the ostrich is hunted, the best being considered those taken from the males and from the living bird; some of the plumage is so coarse as to resemble hair, and the wings have 2 plumeless shafts like porcupines' quills. The best ostrich feathers come from the Levant, and the N. and W. coasts of Africa; \$8,000 to \$10,000 worth have been imported in a year into Marseilles from Alexandria alone; when these feathers were in fashion, £5 or £6 a pound was paid in Grahamstown, S. Africa, and much higher in Europe, but the prices

have since fallen; from 75 to 90 good-sized plumes should weigh a pound. Ostriches inhabit the dry sandy plains of Africa from the Barbary states and Egypt to the Cape of Good Hope; the hearing and sight are very acute, and the length of the neck and high position of the eye enable them to look over the tall herbage and perceive any approaching object at a great distance; generally seen feeding alone in some open spot, they sometimes collect in small flocks where their food is abundant; they are very shy, and when alarmed escape either by a quick stately walk or rapid run with the assistance of the wings. When feeding the stride is from 20 to 22 inches, when walking but not feeding 26 inches, and when terrified from 11½ to 14 feet; taking 12 feet as the average stride, they would accomplish about 25 miles an hour, tasking severely the speed and endurance of the fleetest horse; when at full speed, Livingstone says you can no more see their legs than the spokes of a rapidly revolving carriage wheel; when they begin to run all other game in sight follows the example; they never swerve from the line of direction first adopted. Ostriches are sometimes run down by fleet horses frequently changed, but are generally killed by artifice, one of the most successful modes being that practised by the Bushmen, of clothing themselves in one of their skins, and under cover of this getting near enough the stupid creatures to kill them with a poisoned arrow. When hotly pursued they sometimes turn upon their enemies, giving severe wounds with their feet. Their food consists of fruits, grain, leguminous vegetables, leaves and tender shoots, insects and snails, and such other food as can be picked up, in securing which a considerable quantity of stones is swallowed; the crop is enormous, and the gizzard very powerful; in confinement particularly, it is fond of swallowing all kinds of indigestible substances, some of which may be taken to aid in digestion, but most from mere stupid voracity. It is timid and inoffensive, and its voice is said to resemble the roar of a lion; it is easily tamed, but of little use when domesticated, though some have been trained like beasts of burden, their strength being so great that a large bird can carry a couple of negroes on its back. They are generally said to be polygamous, though Livingstone says not; they begin to lay eggs before a spot has been fixed upon for a nest, and these solitary eggs are often found lying forsaken all over a district; the nest is a simple hollow in the sand, from 3 to 6 feet in diameter, with a shallow border; in this are laid by a single bird or many in company from 12 to 50 or 60 eggs, which are incubated at night and left to the heat of the sun during the day; outside the nest are scattered several eggs, which the Hottentots say are for the first food of the young; the males assist in incubation, and in taking care of the young till they can provide for themselves; when the young attain the size of

a common fowl they run with great speed. The capacity of an ostrich egg is equal to that of 24 hens' eggs, and a single one will weigh 2 or 3 lbs.; the eggs have a strong disagreeable flavor, relished however by the keen appetite of the Bushmen, who not only devour the contents but use the shells as water vessels; entire eggs are often suspended as ornaments in Musulman and even in Christian churches in the East. A Hottentot will devour at a meal a whole ostrich's egg, cooked in a primitive way handed down from remote generations; Burchell ("Travels in Africa") says that they make a small hole in one end, through which by twirling a forked twig they thoroughly mix the white and yolk, and then cook the egg in the shell over the fire—an expeditious, clean, and simple way, requiring, says he, "neither pot nor water, the shell answering perfectly the purpose of the first, and the liquid nature of its contents that of the other." The flesh of the young bird is said to be palatable, being white and coarse, somewhat resembling that of a tough turkey; old birds are apt to be loaded with fat, as much as 20 lbs. being sometimes found in a single one, which is used in cooking and as an external application in rheumatism. Ostriches were well known in ancient times, and their brains used to be served as food on the tables of the luxurious Romans; they are frequently mentioned in Scripture, and a poetical description of them is given in Job xxxix. 18-18.—In the genus *rhea* (Möhr), the *nanndou* or American ostrich, the bill is less thick, and more curved at the tip; the wings are short and imperfect, with long soft feathers; the tail not apparent; toes 3, the inner the shortest. The best known species (*R. Americana*, Lath.) is about half the size of the African ostrich, of a uniform grayish tint, brownish on the back; the head is covered with feathers, and the long plumage of the wings and rump is used only for making feather brushes. It is a shy, solitary, and very fleet bird, yet easily captured on horseback by the lasso, or by tripping it up by throwing at the legs two balls or stones connected by a thong; it runs generally against the wind, using the wings to assist its flight; it can cross rivers, swimming with the body very deep. The food consists of roots, grasses, and sometimes mollusks and fish. The nest is a shallow excavation, in which several females deposit each from 14 to 20 eggs; many eggs are laid scattered over the plain, which the male rolls together with his bill, hatching the young and bravely defending them; it is clearly polygamous. The second species (*R. Darwini*, Gould) is smaller, of a wood-brown tint, with the tips of the feathers whitish; its habits are the same.

OSTROGOTHS. See GOTHS.

OSWEGO, a N. W. co. of N. Y., bounded N. W. by Lake Ontario, intersected by Oswego river, and drained by a number of streams falling into the lake; area, 1,038 sq. m.; pop. in 1855, 69,898. It has a level or undulating sur-

face, and the soil, though generally fertile, varies greatly in different parts. The productions in 1855 were 503,312 bushels of Indian corn, 585,492 of oats, 391,912 of potatoes, 56,896 of wheat, 53,188 tons of hay, 79,446 lbs. of wool, 2,086,174 of butter, and 975,461 of cheese. There were 9 iron furnaces, 6 woollen, cloth, and yarn factories, 42 grist mills, 218 saw mills, 38 tanneries, 8 newspaper offices, 84 churches, and 27,249 pupils attending public schools. The Oswego and Syracuse and the Watertown and Rome railroads traverse the county. Capitals, Oswego and Pulaski.

OSWEGO, a city, port of entry, and semi-capital of Oswego co., N. Y., on Lake Ontario, at the mouth of the Oswego river, by which it is divided into two nearly equal parts; pop. in 1860, 18,000. The river is crossed by two bridges, the lower one an iron bridge with a draw for the passage of vessels. The city is regularly laid out with streets 100 feet in width crossing at right angles. Among the principal public buildings are a fine edifice erected by the U. S. government at a cost of \$130,000, which contains the custom house, post office, and U. S. court room; a court house, city hall, gaol, orphan asylum, city hospital, and city library. It contains 18 churches, viz.: 1 African Methodist, 2 Baptist, 1 Congregational, 1 Lutheran (German), 2 Methodist Episcopal, 1 Presbyterian, 2 Protestant Episcopal, 2 Roman Catholic, and 1 Universalist. There are 2 daily and 2 weekly newspapers published, and liberal provision is made for public schools. Situated at the foot of lake navigation, and having one of the best harbors on Lake Ontario, its commercial facilities are very great, and its trade and wealth constantly increasing. It is connected by the Oswego and Syracuse railroad with the New York central, and with the New York and Erie railroad by the Syracuse and Binghamton. By the Oswego canal, 38 m. long, it communicates with the Erie canal at Syracuse; and by the Welland canal of Canada with all the western ports. Large quantities of western produce and a great portion of the agricultural exports of Canada West pass through this port to the south and east; while the manufactures of the east and the extensive products of the Onondaga salt works flow in a counter current to the west. The foreign commerce for the year ending June 30, 1859, was as follows: exports, \$1,732,582; imports, \$3,637,709; clearances, 1,529, tonnage 252,112; entrances, 1,536, tonnage 252,481; aggregate tonnage of the district, 46,817. Its domestic commerce far exceeds the above; the imports coastwise in 1851 having been to the value of \$6,083,086, the exports coastwise \$11,471,071. On the canal the total tonnage for 1860 was 944,144 tons. The river furnishes abundant water power, and the manufacturing interest is very important. There are 18 flouring mills, with an aggregate of 100 run of stone, and a capacity for grinding and packing 10,000 barrels per day. Of the mills 5 are on the harbor, and elevate their grain from

the lake vessels, and discharge into canal boats; 6 grain warehouses on the harbor elevate and discharge the same way, and the other mills above elevate and discharge into canal boats. On the harbor the elevating capacity is 37,500 bushels per hour, and there is storage for over 2,000,000 bushels of grain. The Oswego starch factory, established in 1848, has a capital of \$450,000 and employs 200 men. It has a main building of 510 feet front by 250 feet deep, which uses 500,000 bushels of grain and turns out 12,000,000 lbs. of starch per annum. There are various other manufactories in successful operation. The harbor is protected by Fort Oswego.

OTAHETTE. See SOCIETY ISLANDS.

OTHMAN, or OSMAN, the founder of the Ottoman empire, born in Surgut, in Bithynia, in 1259, died in 1326. He is said to have been the son of Orthogrul, the leader of a horde of Turcomans who had entered into the service of the sultan of Iconium. Othman succeeded his father in the command, and on the death of Masud II., the last Persian emperor of the Seljookian dynasty, received part of the province of Bithynia as his share in the division of the empire. Immediately afterward he attacked the Byzantine empire, leading his forces in July, 1299, through the unguarded passes of Mt. Olympus, and conquering the territory of Nicæa except the capital, which did not yield until 4 years later. The 27 years of Othman's reign are taken up with a series of wars, by means of which he slowly enlarged his dominions. He reduced the province of Marmora in 1309, subdued the whole of Bithynia and neighboring provinces, and by fortifying defensible posts gradually pushed on his conquests. Several times he had been repulsed in attacks upon Nicomedia (Isnik) and Prusa (Broussa); but the capture of the latter place by his son Orchan, the news of which event reached him on his dying bed, laid the foundation of the Turkish empire. From him it is called the Ottoman Porte; yet he never assumed the title of sultan, although he held a court at Cara-Hissar, and money was coined in his name. By the Turks his memory is held in great veneration.

OTHMAN IBN AFFAN, the 8d oriental caliph of the Arabian dynasty, assassinated in Medina in 655. He was one of the earliest followers of the prophet, accompanied him in his flight from Mecca to Medina, and became on his return one of his secretaries. Designated by Omar as one of the 6 individuals to choose his successor, he himself was selected, on condition that he would govern the country according to the rules of the Koran, and ascended the throne at the close of 644. In 645 one of his armies reduced the province of Hamadan, and in 646 another expelled Yezdegerd from Persia, while a third took the principal cities of eastern Africa, after defeating near Tripoli Gregorius, who commanded in the name of the Greek emperor. Incursions were also made into Nubia, and in 648 the islands of Cyprus and Rhodes were plundered, these being the first maritime

expeditions undertaken by the Arabs. But although fortunate in war, his domestic administration became unpopular on account of his partiality to his family and favorites, removing valuable officers to make way for these. He lost the silver signet ring used by the prophet, and considered by the Moslems as the palladium of their empire, and also gave offence by occupying the pulpit when in the mosque at prayers, instead of a few steps lower down, as had been the custom of his predecessors, except Mohammed. The discontent broke out into an open insurrection, in which Othman's life was nearly lost, and which was quieted with some difficulty by concessions. But Ayesha, the widow of the prophet, an enemy of the caliph, bribed Othman's secretary to send in his master's name a false order to the governor of Egypt, commanding him to put to death Mohammed, son of Abubekr; whereupon the latter marched to Medina, entered it unopposed, and invested the palace. Deserted by his soldiers, Othman, putting the Koran in his bosom, calmly awaited his fate. He was assassinated at the age of 82, or according to some of 90 or 95. He was the first caliph who caused an authentic copy of the Koran to be transcribed, the revision being intrusted to companions of the prophet.

OTHMAN IBN YAHIA ALCAISI, a Moorish scholar, born in Malaga, died in 1834. Little is known of him, but he is mentioned as having possessed great and varied talents, and was the author of a work entitled *Quæstia Grammatica*, and of treatises *De Hereditate* and *De Mensuris Hispanis*. He was made governor of Malaga.

OTHO, MARCUS SALVUS, a Roman emperor, born A.D. 82, died in 69. His family, originally of Ferentinum, traced its origin to the kings of Etruria. His father, Lucius Otho, held many places of honor and trust under the emperor Tiberius. During the early years of Nero's reign Marcus Otho was his intimate associate in various excesses and debaucheries; but Nero's love for Poppæa, whom Otho had seduced from her husband, caused a coolness between them, and Otho was virtually banished by an appointment as governor of Lusitania, where he remained 10 years. He was afterward active in the opposition to Nero, and aided in placing Galba on the throne, A. D. 68. As a reward for this service, he expected to be named Galba's successor, but the latter adopted Piso Licinianus. This disappointment, his jealousy against Piso, and his heavy debts, made him desperate; and he said publicly that if he were not emperor soon he would be ruined. He accordingly conspired among the guards, who proclaimed him emperor, and put Galba to death, after a reign of 7 months. But a few days before this event the legions in Germany had proclaimed their general Vitellius emperor, and Otho was scarcely seated upon the throne when he was called upon to oppose this new claimant. After an offer of a large sum to Vitellius to relinquish his claim, which was re-

fused, he marched against him with an army, and beat the forces of Vitellius in 3 battles; but in a general engagement near Bedriacum, on the Po, S. W. of Mantua, the army of Otho was completely defeated after a hard-fought battle. Otho himself was not upon the field, and when the news was brought to him, he fell upon his sword, having reigned only 95 days.

OTHO I., THE GREAT, a German emperor, born in 912, died at Memleben, Thuringia, May 7, 978. In spite of the existence of a strong opposition to him in his own family, he succeeded his father, Henry the Fowler, and was crowned at Aix la Chapelle in 936. His whole reign of 86 years was a constant series of long and bloody wars. After quieting the opposition to himself, he was engaged in a struggle which lasted from 938 to 950 with Boleslas, duke of Bohemia, who was finally subdued and obliged to reinstate the Christian religion. He was also involved in a war with the dukes of Bavaria and Franconia, in which he was triumphant; and he strengthened his authority still more by conferring in 949 the duchy of Swabia upon his son Ludolf, that of Bavaria upon his brother Henry, and that of Lorraine upon his son-in-law Conrad, count of Worms. No less successful against foreign enemies, he made the Slavic tribes tributary as far as the Oder, and drove back the Danes, who had invaded Germany, across the Elbe, and compelled their king to acknowledge his authority. In 946 he undertook a journey to France to aid his brother-in-law Louis (Outremer) against Hugo the Great, count of Paris, and, composing the differences between the king and his vassals, received as a reward all of Lorraine that was still in French hands. Invited by Adelaide of Burgundy, the beautiful widow of Lothaire, whose throne had been usurped by Berengarius II., he crossed the Alps in 951, defeated Berengarius, took Pavia, was crowned king of Lombardy, married Adelaide, and returned to Germany. But on account of Otho's affection for his wife, and for Henry, duke of Bavaria, the enemies of both, headed by Ludolf, his son by his first wife (Eadgith, sister of the English king Athelstan), and by Conrad, duke of Lorraine, raised a civil war, which was not effectually quelled until 954. In the mean time the Hungarians had invaded Germany, and, renewing their incursion in 955, besieged Augsburg, and were defeated (Aug. 10) on the Lechfeld near that city with terrible slaughter. Berengarius revolting, Otho again passed over into Italy, and was crowned king of that country by the archbishop of Mentz, and on Feb. 2, 962, was crowned emperor of the West by Pope John XII. The pope after his departure breaking his allegiance, Otho hastened again to Italy, and called a council which deposed John, and chose in his place Leo VIII. The Romans soon after having expelled Leo and recalled John, Otho returned, besieged and took Rome, deprived Benedict V., the successor of John, of his popedom, and reinstated Leo. His plan

of forming an alliance with the Greek empire, by marrying his son Otho to Theophania, having been defeated by the obstinacy of the Byzantine court, Otho invaded lower Italy, defeated the Greeks, and took Apulia and Calabria. The new emperor of the East, John Zimisces, hereupon eagerly consented to his wish, and an alliance was formed. Soon afterward Otho died in the height of his fame. He had during his reign founded the dukedom of Carinthia, created the two new marches of East and North Saxony, conquered Austria and upper and middle Italy, and begun the subjection of lower Italy.

OTHO II., a German emperor, son of the preceding, born in 956, died in Rome, Dec. 7, 983. He was crowned king of Rome during the lifetime of his father. He ruled for a time under the guardianship of his mother, but finally retired from court, and a civil war sprang up, in which he was opposed by his cousin Henry, duke of Bavaria, assisted by Harold, king of Denmark, and others. Otho defeated his cousin in 977, and gave Bavaria to his nephew, Otho, duke of Swabia. The French king Lothaire having invaded Lorraine in 978 and taken Aix la Chapelle, Otho collected an army, drove back the invaders, and in the pursuit overran Champagne and marched to Paris, a suburb of which he burned. Civil war having broken out in Rome, he passed over into Italy in 979, repressed the dissensions there, and then marched into lower Italy with the intention of wresting from the Greeks Apulia and Calabria. For a time he was successful, and took Naples, Salerno, and in 982 Taranto; but on July 18 of that year he was totally defeated at Basantello in Calabria by the Greeks, who had called in to their aid the Saracens of Sicily. Otho himself narrowly escaped. While meditating another expedition he died. He was of a daring and fierce disposition, ever forming great projects, but always hasty in their execution.

OTHO III., a German emperor, son of the preceding, born in 980, died in Paterno, near Viterbo, Jan. 21, 1002. When 3 years old he was crowned emperor, and during his minority the government was administered by his mother Theophania, his grandmother Adelaide, and the archbishop of Mentz. During his reign Germany was a scene of constant tumults and wars. Henry, duke of Bavaria, attempted to gain possession of his person while he was a child, but was defeated. In 984 Lorraine was invaded by Lothaire, king of France, who did not succeed in effecting any thing. In 996 he went to Italy, repressed the insurrection of Crescentius, placed one of his relatives, Bruno, on the papal throne under the name of Gregory V., and on May 21 was by him crowned emperor. After his departure Crescentius renewed his insurrection, and drove out Gregory. Otho returned in 998 and put Crescentius to death, and in 1000 made a pilgrimage to the grave of St. Adalbert, at Gnesen in Poland, and founded there an archbishopric. Visiting

Italy again in 1001, he was compelled to leave Rome on account of the hostility of the people, and shortly afterward died of fever, or according to some of poison, furnished by the widow of Crescentius. With him the male branch of the Saxon line disappeared. He was succeeded by Henry II.

OTHO IV., a German emperor, born in 1174, died May 19, 1218. He was the son of Henry the Lion, duke of Saxony and Bavaria, and of Matilda, sister to Richard Cœur de Lion. His youth was passed at the court of England. In 1197 the emperor Henry VI. of the house of Hohenstaufen died, and left his crown to his son Frederic II., then an infant. Otho was at that time duke of Saxony, and supported by the Guelphs; and disregarding the true heir, he claimed the imperial throne. His claim was opposed by Philip of Swabia, who had the support of the Ghibellines. A civil war ensued, which ended after 8 years by the flight of Otho to England, and Philip held the throne till 1208; when he was assassinated. Otho thereupon returned, was recognized throughout Germany as emperor, and was crowned at Rome by Pope Innocent III. in 1209. The pope made it a condition of this coronation that Otho should relinquish in favor of the church the nomination to certain benefices that had been an imperial prerogative, and exacted an oath to that effect; but the emperor violated his oath, and was excommunicated by the pope and formally deposed by the imperial electors. The rightful heir Frederic, then king of Naples and Sicily, was elected in his place. A second civil war now began, and the alliance of Otho with John, king of England, added to his enemies the king of France, Philip Augustus, by whom he was beaten and irretrievably ruined at the battle of Bovines in 1214. He made no further effort to regain the crown, but spent his remaining years in privacy and devotional exercises at his castle of Hartzburg.

OTHO I., king of Greece, 2d son of Louis I., king of Bavaria, born in Salzburg, June 1, 1815. In his 17th year he was invited by the Greeks, who had then recently achieved their independence, to fill their throne; and the proposition being approved by the governments of Great Britain, France, and Russia, in a treaty concluded in London in May, 1832, and ratified soon after by the king of Bavaria, the young prince accepted the offer, and on Jan. 25, 1833, made his solemn entrance into Nauplia, accompanied by several officers of state who were to have the control of public affairs until he attained the age of 20. In June, 1835, he assumed the reins of government, and in the succeeding year was married in Germany to the princess Frederica Amelia of Oldenburg. The Bavarian ministers to whom he committed the management of the kingdom soon became unpopular, and as early as 1836 the people began to manifest their discontent by open rebellion. Since that time the breach between them and the king has never been wholly repaired, the former chafing

under an administration composed largely of foreigners, and the latter wanting the tact or energy to offer any available plan of conciliation. Upon the day of his arrival with his consort at the Piræus, Feb. 14, 1837, he signed a decree removing some of the most obnoxious foreigners from office, and substituting the Greek language for the German in official documents. In other respects, however, the government continued to be a despotic one; and in Sept. 1848, the Greeks, despairing of procuring in any other way the constitution which they had been induced to expect from the king, surrounded his palace, and compelled him to form a cabinet in which his native subjects should be properly represented, and to call a national assembly to frame a constitution. The latter instrument was promulgated in the ensuing March, the Bavarian ministers were sent home, and an auspicious era seemed about to dawn upon Greece. The reactionary tendencies of the king and his advisers soon interfered with these prospects; attempts were made to remodel or abridge the concessions granted to the people, which the latter naturally resisted; ministry after ministry essayed without success to carry on the government; and under the influence of the queen, who is strongly pro-Russian in politics, the kingdom has become virtually an outpost of the Russian empire. So openly was the sympathy of the Greeks for the Russians manifested in the Crimean war, that an allied army of English and French was stationed at the Piræus, and a new ministry, distasteful to the king and queen, was forced into office. The people, perceiving in this an attempt to infringe the royal prerogative, sided for once with their sovereign, and the unpopular ministers were obliged to retire. Otho having no children by his marriage, the crown descends by special limitation to Adalbert of Bavaria, his brother.

OTIS, HARRISON GRAY, an American orator and statesman, born in Boston, Oct. 8, 1766, died there, Oct. 28, 1848. He was a nephew of James Otis, and the son of Samuel Allyne Otis, who was the first secretary of the U. S. senate, which office he held from the formation of the government till his death in 1814, without having been absent from his post one day. Harrison Gray Otis received his early education at the Latin school of his native town, and was graduated at Harvard college in 1788. He studied law with Judge John Lowell, and was admitted to the bar in 1786. His success as a lawyer was rapid and brilliant, and he soon became distinguished for his eloquence and grace as a public speaker. In 1796 he was elected a representative from Boston to the state legislature, and in the same year was chosen to succeed Fisher Ames in congress, where he soon became a prominent leader of the federal party. He served two terms in congress, and on his retirement in 1801 was appointed U. S. district attorney for Massachusetts. Subsequently he became a member of the state legislature, and was speaker of the

house from 1803 to 1805; and in 1805 and for many successive years he was president of the senate. He was chairman of the legislative committee which in 1814 reported in favor of calling a convention of the New England states at Hartford to consider the best mode of redressing the grievances inflicted on those states by the war with Great Britain. He was a leading member of that convention, and was one of the three commissioners appointed by Massachusetts to go to Washington and make a representation to the federal government. In his "Letters in Defence of the Hartford Convention" (Boston, 1824) he warmly vindicated the character and intentions of that body. In 1814 Mr. Otis was appointed judge of the court of common pleas of Massachusetts, which office he held till 1818, when he took his seat in the U. S. senate, to which the legislature had elected him in the preceding year. In 1820, in reply to Mr. Pinckney in the debate on the Missouri question, he advocated with great force and eloquence the restriction of the extension of slavery. His term expired in 1828, and in the same year he became the federal candidate for governor of Massachusetts, but was defeated. In 1829 he was elected mayor of Boston, which office he held till 1832, when he retired from public life. "He was never rivalled," says the author of "The Hundred Boston Orators," "for eloquence by any politician of his native city or any of his native state, excepting only his noble kinsman and the accomplished Fisher Ames. The contour of his head was beautiful, with animated eyes and a ruddy complexion. He was rather tall, of noble bearing, graceful gestures, and courteous manners. William Sullivan aptly remarks of him that he was the orator of all popular assemblies—the guide of popular opinion in all the trying scenes of commercial restriction, embargo, and war. With a fine person and commanding eloquence, with a clear perception and patriotic purpose, he was the first among his equals, alike ready at all times with his pen and his tongue."

OTIS, JAMES, an American orator, born in West Barnstable, Mass., Feb. 5, 1725, died in Andover, May 28, 1788. He was graduated at Harvard college in 1743, studied law in Boston, was admitted to the bar in 1748 in Plymouth, where he was then residing, and in 1750 removed to Boston. In 1760 he published a treatise entitled the "Rudiments of Latin Prosody, with a Dissertation on Letters, and the Principles of Harmony in Poetic and Prosaic Composition." His public career dates from his argument, in 1761, on the question whether the persons employed in enforcing the acts of trade should have the power to invoke generally the assistance of all the executive officers of the colony. Otis was at that time advocate-general, but, deeming the writs of assistance illegal, refused to argue in behalf of them, and resigned. He was then employed upon the other side, and his speech on the occasion produced a profound impression. "Otis was a flame of fire," says

John Adams; "with a promptitude of classical allusions, a depth of research, a rapid summary of historical events and dates, a profusion of legal authorities, a prophetic glance of his eyes into futurity, and a rapid torrent of impetuous eloquence, he hurried away all before him. American independence was then and there born. Every man of an immense crowded audience appeared to me to go away as I did, ready to take arms against the writs of assistance." The judges evaded giving a decision; and the writs, although secretly granted at the next term, were never executed. The next year Otis was elected to the legislature, in which body his fiery spirit and impassioned eloquence soon placed him at the head of the popular party, and justified his claim to the title of the "great incendiary of New England." On June 6, 1765, he introduced a motion advising the calling of a congress of delegates from the several colonies. The motion was adopted, and a circular letter was sent to the other colonies, in consequence of which the stamp act congress met in New York in October of that year. Otis was one of the delegates to this body, and a member of the committee to prepare an address to the house of commons. When Charles Townsend's plan of taxation had passed parliament, the Massachusetts house sent in 1768 another circular letter requesting the colonies to unite in some suitable measures of redress. On the message of Gov. Bernard requiring the letter to be rescinded Otis made a speech, pronounced by the friends of the government to be "the most violent, insolent, abusive, and treasonable declaration that perhaps ever was delivered." The house refused to rescind by a vote of 92 to 17. In the summer of 1769, finding that the commissioners of customs had sent accusations against him to England, charging him with treason, he inserted an advertisement in the "Boston Gazette," denouncing them in a bitter manner. The next evening he met Robinson, one of the commissioners, in a coffee house. An altercation ensued, ending in an affray, in which Otis was overpowered by numbers, and severely injured. To a cut in the head received on this occasion his subsequent derangement is attributed. In the action instituted against Robinson, he obtained an award of £2,000, which however he gave up on receiving from the defendant a humble written apology. In 1770 he retired to the country for his health, but in 1771 was again chosen a representative. This was his last appearance in public life, except at long intervals. Nearly all the rest of his life he was deranged. During the last two years, which were spent at Andover, his mind was thought to be restored, and he returned to Boston and resumed the practice of law. But the lucid interval proving only temporary, he went back to Andover, and was shortly after killed by a stroke of lightning while standing at the door of the house in which he lodged. During his derangement he destroyed all his papers. He had previously published pamphlets entitled

"A Vindication of the Conduct of the House of Representatives" (1762); "The Rights of the British Colonies asserted" (1764); and "Considerations on behalf of the Colonists" (1765). His temper was irritable and impulsive; but he was easily conciliated, and his public course in consequence often appeared inconsistent.

OTOMI, one of the principal aboriginal families of Mexico, at one time having their seat on the plain of Mexico, but subsequently incorporated in the republic of Tlascala. Although, according to tradition, springing from the same root with the Nahuatlacas, they spoke a language radically different, and in nearly all respects peculiar, being essentially monosyllabic. The words consist of one or two syllables; those of three are supposed to have been formed after the Spanish conquest. Each syllable has a meaning; and in words of more than one syllable each preserves its primitive meaning. There are but few exceptions to these rules. Comparisons have been instituted between the Otomi and Chinese, which is also monosyllabic, and many sweeping inferences drawn from this common peculiarity; but they have no strong vocal resemblances, and probably approximate only in those particulars which are the necessary consequence of their monosyllabic character. The Otomi is the exceptional language of America; that is to say, it has fewer elements in common with the American system of languages than any other on the continent. In this respect it holds a position corresponding with that of the Basque in Europe.

OTRANTO (anc. *Hydruntum*), a seaport town of Naples, situated on a strait of the same name at the E. extremity of what is called "the heel" of Italy, opposite Cape Lingetta in Albania, 28 m. S. E. from Lecce; pop. about 5,000. The town has received celebrity from the title of Walpole's romance. It contains a cathedral and some Roman remains. It was taken by the Turks in 1480, and seems to have never recovered from the check then given to its prosperity. Under the first French empire it gave the title of duke to Fouché, Napoleon's minister of police.—The ancient Hydruntum, on a branch of the Appian way, was the great highroad of traffic between Greece and Rome.

OTRANTO, DUKE OF. See Fouché.

OTSEGO, a central co. of N. Y., bounded W. by the Unadilla river, and watered by the Susquehanna river and Wharton, Butternut, Otego, Schenemas, and other creeks; area about 1,050 sq. m.; pop. in 1855, 49,735. Its surface is traversed from N. E. to S. W. by several ridges, between which are broad valleys. Otego lake, 8 m. long and 1 m. broad, is in the N. E., and has an elevation of 1,193 feet above tide; and Schuyler lake, about 3½ m. long, is in the N. W. The soil is various in quality, but generally fertile. The agricultural productions in 1855, the largest of any county in the state, were 59,124 bushels of wheat, 903,647 of oats, 840,170 of Indian corn, 412,703 of potatoes, 108,069 tons of hay, 3,075,206 lbs. of butter, 1,638,493 of

cheese, and 3,122,258 of hops. There were 7 cotton factories, 37 grist mills, 142 saw mills, 26 tanneries, 117 churches, and 18,131 pupils attending public schools. Capital, Cooperstown.

OTTAR OF ROSES. See ATTAR OF ROSES.

OTTAWA. I. A N. co. of Ohio, bounded N. E. by Lake Erie and S. E. by Sandusky bay, and intersected by Portage river; area, about 850 sq. m.; pop. in 1850, 3,808. It has a nearly level surface and fertile soil. The productions in 1850 were 55,584 bushels of Indian corn, 23,288 of wheat, 12,968 of oats, 10,326 lbs. of wool, and 4,445 tons of hay. There were 5 churches, and 1,294 pupils attending public schools. It is intersected by the Cleveland and Toledo railroad, which passes through the capital, Port Clinton. II. A W. co. of Mich., bordering on Lake Michigan, intersected by the White, Muskegon, and Grand rivers, and also drained by Black and Pigeon rivers and Crookery creek; area, about 1,000 sq. m.; pop. in 1850, 5,587; in 1860, 13,222. It has an undulating surface and fertile soil. The productions in 1850 were 3,814 bushels of wheat, 23,995 of Indian corn, 25,152 of potatoes, and 1,502 tons of hay. The Detroit and Milwaukee railroad intersects the county, having its terminus at the capital, Grand Haven, opposite Milwaukee, with which it has steamboat communication.

OTTAWA, a city and the capital of La Salle co., Ill., situated at the junction and on both sides of the Illinois and Fox rivers, and on the line of the Chicago and Rock Island railroad, 84 m. S. W. from Chicago, with which it is also connected by the Illinois and Michigan canal; pop. in 1860, 7,000. The place has an active trade, principally in breadstuffs, of which it exports probably more than any other interior city of the state. It has also some heavy manufacturing establishments, chief among which is a starch factory in successful operation, with capacity to consume 700 bushels of corn per day. It has also 5 flouring mills, several founderies and machine shops, planing mills, &c. The Fox river has here a fall of 29 feet, affording immense water power. The city is well provided with public schools and churches.

OTTAWA, Canada. See BYTOWN.

OTTAWA RIVER. See CANADA, vol. iv. p. 829.

OTTER, the name of several species of carnivorous mammals, of the sub-family *lutrina*, and family *mustelida* or weasels. The sub-family includes the 4 genera *lutra* (Linn.), *pteronura* (Gray) or *pterura* (Wieg.), *enhydra* (Fleming), and *aonyx* (Lesson); they are all eminently aquatic animals, feeding principally upon fish. In the genus *lutra* the dentition is: incisors $\frac{3}{2}$ - $\frac{3}{2}$, canines $\frac{1}{1}$ - $\frac{1}{1}$, premolars $\frac{3}{2}$ - $\frac{3}{2}$, molars $\frac{1}{1}$ - $\frac{1}{1}$ = 36; the upper laniary is very large, with a large accessory internal tubercle, and the lower posteriorly tuberculated; the ears are small and far apart; the head broad and blunt, and flat above; the body thick and elongated; the feet short and webbed; tail long, round, depressed toward the tip, and flat

beneath. The species are found in all parts of the globe, and are distinguished with difficulty from the similarity of their colors. The American otter (*L. Canadensis*, Sab.) is about 4½ feet long, of which the tail is 1½, and the weight from 20 to 25 lbs.; a considerable part of the muzzle is bare, and the nostrils are large and open; the eyes very small, and very far forward; the neck long; legs short and stout. The color above is dark glossy brown, slightly lighter beneath, lower surface and sides of the head and neck dusky white. Rather awkward on land, it is a very expert diver and rapid swimmer, and very voracious; it often remains more than a minute under water, retiring with its fishy prey to a half-sunken log or the shore to devour it; it frequents clear and rapid streams or large ponds, and makes a burrow in the banks, lined with leaves and grasses, the entrance being under water. Otters have a singular habit of sliding down wet and muddy banks or icy slopes, apparently for sport, of which the hunters take advantage by setting traps at the foot of the slide; they are also taken in sunken traps baited with fish; when killed in the water, the body sinks from the solidity of the bones. When taken young, they are easily domesticated. They bring forth a litter of 2 or 3, between February and April, according to latitude. They are found over almost the whole of North America, and perhaps a portion of South America; rare in the Atlantic states, they are not abundant anywhere in the settled regions, but most so in the British possessions, whence several thousand skins are annually carried to England; a good skin is worth from \$4 to \$8, according to the size and the darkness and fineness of the fur; the fur is of two kinds, like that of the beaver, one being short, soft, and dense, the other longer, coarser, and scattered through the first, and it is much esteemed for caps and gloves. The *L. latarina*, or *latarina mollis* of Gray, is only the Carolina variety of the Canada otter; and the *L. Californica* (Gray) is perhaps also only a western variety. The *L. Brasiliensis* (Ray), the *lontra* or river wolf of South America, is a distinct species, having the muzzle entirely hairy except around the nostrils; the color is yellowish brown, and the throat whitish; the length is about 3½ feet; they live in troops, rising frequently to the surface of the streams, and snapping like dogs. The European otter (*L. vulgaris*, Erxl.) is about 8½ feet long, of which the tail is 15 inches, resembling in colors and in habits the Canada otter; its fur is valuable, and its flesh, like that of several other aquatic mammals, may be eaten by Catholics during Lent. It is found throughout Europe and northern and temperate Asia, and its hunting affords great sport. The Pondicherry otter (*L. nair*, F. Cuv.), probably a variety of the common species, is frequently domesticated, and taught to drive fish into the nets, or even to catch them in the teeth and bring them to its master.—In the

genus *pteronura* (Gray) the muzzle is hairy; the feet large and widely webbed; the tail elongated, sub-cylindrical, with a fin-like dilatation on each side of the hinder half; it seems intermediate between *lutra* and *enhydra*. The *P. Sambachii* (Gray), from Demerara, is of liver-brown color, with chin and throat yellowish; the length is about 28 inches, of which the tail is 12; the genus is peculiar to South America, and may be distinguished from *enhydra* by the greater size of the fore and the lesser of the hind feet. Delalande discovered at the Cape of Good Hope an otter which has no claws on the fore feet, and mere vestiges of them on the hind in the adult condition; of this Lesson formed the genus *onyx*. The clawless otter (*A. inunguis*, Less.) is larger than the European otter, with longer legs and less palmated feet; the color is chestnut brown above, grayish on the head and shoulders, and whitish below.—The sea otter (*enhydra marina*, Flem.) resembles a seal more than an otter; the head is short and very broad, the ears very small, the nose with a naked muffle; the toes of the fore feet very short, bound in a thickened membrane, densely haired and covering the claws; in the hind feet the outer toe is the longest, and these extremities are far backward as in the seals; there is one premolar less on each side of the upper jaw, and the adults are said to have only 4 lower incisors; in vol. iii. of Audubon and Bachman's "Quadrupeds of North America," p. 170, the dental formula is given as: incisors $\frac{1}{2}$, canines $\frac{1}{2}$, molars $\frac{1}{2}$ = 38. The body is very long, covered with a thick glossy fur; tail less than $\frac{1}{2}$ the length of the body, strong and depressed. The length in the adult is more than 5 feet, of which the tail is 1 foot; there are 3 ventral mammae; this is the only described species. The color is chestnut brown, but black in the adult in the proper season; there is a grayish tint about the head and neck; the fur is exceedingly fine and long. It inhabits the coasts and islands of the north Pacific and about Kamtschatka, coming down on the American coast as far as Monterey; it is essentially marine in its habitat, sometimes going far from the shore, but generally keeping near the coast both for shelter and food; it is shy and timid, and generally hunted from boats. The skins used to form an important article of commerce between the Russians and the Chinese and Japanese merchants, in whose countries the fur is highly esteemed; a common price for a single skin used to be \$30 or \$40. It is found principally between lat. 49° and 60° N. on the N. W. coast of America; the animal is now comparatively rare, except on the coasts above the influence of the California gold fever. The food consists of fish, lobsters, and cephalopods. It is stupid and inoffensive, and trusts for escape from its pursuers only to its speed in swimming; it produces on land a single young one at a birth; the flesh of the young is said to be relished by the hunters. The habits of

this singular animal are but little known, and perfect skins and skulls are exceedingly rare either in private or public collections.

OTTERBEIN, PHILIP WILLIAM, the founder of the church of the United Brethren in Christ, born in Dillenburg, Germany, June 4, 1726, died in Baltimore, Md., Nov. 17, 1818. He was ordained to the ministry in the Reformed church at Herborn in 1749. In 1752 he was sent to America as a missionary, under the auspices of the synod of Holland. He was first settled at Lancaster, Penn.; afterward served congregations at Tulpehocken and York, Penn., and Frederic, Md.; and in 1774 went to Baltimore, where he established an independent congregation, over which he presided about 40 years. At Lancaster, shortly after his arrival in this country, he experienced what he regarded as a change of heart, and as a consequence was led to adopt what were then looked upon as "new measures," such as prayer meetings, class meetings, and open air meetings held in groves during several successive days. Although he was a settled pastor, he made numerous and long itinerant tours. He soon associated with himself other preachers of like faith and zeal; and at the time of his death there were united with him in the church to which his labors gave rise about 100 preachers and 20,000 members. He was a man of extensive learning, spoke and wrote the Latin language with great ease, and was characterized by earnest piety and quenchless zeal. When the Methodist preachers came to Pennsylvania and Maryland, he coöperated with them, and assisted Dr. Coke in the ordination of Francis Asbury. The church to whose interests his life was devoted is spread over large portions of the northern and southern states, and numbered in 1859 about 84,000 communicants.

OTTO OF ROSES. See ATTAR OF ROSES.

OTTOCAR II., king of Bohemia, born about 1230, killed in battle, Aug. 26, 1278. During his youth he headed an insurrection against his father, King Wenceslas I., which for a time was successful, but resulted finally in his defeat and imprisonment. After his release he gained possession of Austria and Styria by marrying Margaret, the widow of the duke of Austria, although she at that time was 46 years old, and he himself but 23. For the maintenance of these acquisitions he had during the earlier part of his reign many and severe struggles with the Bavarians and Hungarians. He ascended the throne in 1253, and in 1254 undertook a crusade against the pagan Prussians, which was completely successful; and during this campaign he built the city of Königsberg. Having divorced his wife, he married the Hungarian princess Cunigunda in 1261, and in 1269 the duchies of Carinthia and Carniola came into his power. His dominions now extended from the borders of Bavaria to Raab in Hungary, and from the Adriatic to the Bal-

tic. After the death of Richard of Cornwall, the emperor of Germany, he and Alfonso of Castile were candidates for the succession; but the choice fell on Rudolph, count of Hapsburg. Ottocar refused to submit to the authority of the elected monarch; but on Rudolph's marching into his dominions and laying siege to Vienna, he consented to a compromise in which he was obliged to give up his claims to Austria, Styria, Carinthia, Carniola, and the Wendish territory, and submit to other humiliating conditions. Not long after, however, he broke the treaty, and placed himself once more in hostility with the empire, but was defeated and slain in a battle with the imperial troops between Weidendorf and Jedensberg, usually called the battle of the Marchfeld, from the field on the March on which it was fought. Ottocar, though a haughty and luxurious prince, did great service to his country by repressing the power of the nobility, by the elevation of the middle classes and the protection of the peasants, by the founding of cities and schools, and the better administration of justice. He was succeeded by his son Wenceslas II., the last but one, in male line, of the house of Przemysl.

OTTOMAN EMPIRE. See TURKEY.

OTWAY, THOMAS, an English poet, born in Trotton, Sussex, March 3, 1651, died in London, April 14, 1685. He was educated at Winchester and at Christchurch, Oxford, but left the university without taking a degree, and set out for London, where through necessity he became an actor in 1672. He appeared only once, however, for "he being not used to the stage," says Downes in his *Roccius Anglicanus*, "the full house put him to such a sweat and tremendous agony, being dash't, spoilt him for an actor." The next 8 years he led a dissolute life, his wit introducing him to the society of young men of fashion. He did not begin writing till 1675, when his tragedy of "Alcibiades" appeared. Patronized by the earl of Rochester, who had recently quarrelled with Dryden, he brought out the next year "Don Carlos," which was very successful, and "got more money than any preceding modern tragedy." In 1677 his tragedy of "Titus and Berenice," translated from Racine, and his farce "The Cheats of Scapin," from Molière, were acted; and the same year he produced a comedy entitled "Friendship in Fashion," remarkable for its want of wit and decency, and which, though considered "very diverting" at the time, was hissed off the stage in 1749 for its immorality. In 1677 Otway received through the agency of the earl of Plymouth, the king's natural son, a commission as cornet in a regiment of horse designed for Flanders. But the troops being shortly after disbanded, he returned to London miserably poor, and began again to write. His situation was now deplorable. Rochester had become his enemy, and satirized him in a lampoon entitled "A Session of the Poets," because Otway had presumed to fall in love with a famous actress, Mrs. Barry, to whom Rochester at that

time was attached. In 1680 Otway produced the tragedy of "Caius Marius," which met with considerable success; and having ranged himself on the side of Dryden and the Tories, he took the opportunity of satirizing the opposite party both in this play and in "The Poet's Complaint to the Muse," published the same year. His tragedy of "The Orphan" appeared in 1680. "This is one of the few plays," says Johnson, "that keep possession of the stage, and has pleased for almost a century through all the vicissitudes of dramatic fashion. It is a domestic tragedy drawn from middle life. Its whole power is upon the affections; for it is not written with much comprehension of thought or elegance of expression." Reduced to the necessity of writing for his bread, he produced in 1681 "The Soldier's Fortune," and in 1684 its second part, "The Atheists," both of which were successful. His greatest performance, however, was "Venice Preserved," which afforded him a field for the display of his peculiar pathetic power. This was first performed in 1682, and is still occasionally acted. Otway wrote also some minor poems, and translated from the French the "History of the Triumvirate," but his early death prevented him from fulfilling the promise of poetic excellence which he had given. "He died," says Dr. Johnson, "in a manner which I am unwilling to mention. Having been compelled by his necessities to contract debts, and hunted, as is supposed, by the terriers of the law, he retired to a public house on Tower hill, where he is said to have died of want; or, as it is related by one of his biographers, by swallowing, after a long fast, a piece of bread which charity had supplied. He went out, as is reported, almost in the rage of hunger, and finding a gentleman in a neighboring coffee house, asked him for a shilling. The gentleman gave him a guinea; and Otway, going away, bought a roll, and was choked with the first mouthful. All this, I hope, is not true; and there is this ground of better hope, that Pope, who lived near enough to be well informed, relates in Spence's 'Memorials' that he died of a fever, caught by violent pursuit of a thief that had robbed one of his friends. But that indigence, and its concomitants sorrow and despondency, pressed hard upon him, has never been denied, whatever immediate cause might bring him to the grave." The account given by Pope of his death is now generally believed to be the more trustworthy.

OUDE, a British province in the N. part of Hindostan, lying between lat. 25° 24' and 29° 6' N., and long. 79° 45' and 83° 11' E., bounded N. and N. E. by Nepaul, E. by the British districts of Goruckpoor, Azimgurh, and Jounpoor, S. by Allahabad and Cawnpore, S. W. and W. by Furruckabad and Shahjehanpoor, and N. W. by Pilleebheet and Kumaon; length from S. E. to N. W. 270 m., breadth 160 m.; area, 28,788 sq. m.; pop. 2,970,000. It belongs for the most part to the great plain of Hindostan, but rises gradually toward

the N. W., and in the N. E. and N. reaches the base of the Sub-Himalaya or continuation of the Sivalik range. A part of this latter region belongs to the Terai, a black marshy tract stretching along the borders of Nepaul, and covered with almost impenetrable forests. With the exception of this frontier region, the whole country is almost a dead level. The principal rivers are the Ganges, which forms the S. and S. W. boundary, the Sae, Goomtee, Goggra or Sarjou, Ramgunga, and Raptée, all of which have a general S. E. course. Though most of them are streams of considerable magnitude, they are constantly decreasing in volume, and within the present century the Goomtee has fallen 5 or 6 feet—a fact which has been attributed in part to the clearing of so much of the jungles from which the rivers received numerous streamlets. The annual fall of rain is also thought to be diminishing, and water is obtained from wells with less facility than it was formerly. The rivers are all very tortuous, and are subject to great changes of volume at different times in the year, the Ganges and Goggra rising in the rainy season as much as 30 feet. The Ganges also annually changes its course within the limits of a bed 4 m. in average width. There are no permanent lakes, but large ponds called *jhils* are formed by the rains in the wet season, and generally dry up or are drained off by the rivers in hot weather. The largest of these, situated 8 m. N. W. from Mankipoor, in a deserted channel of the Ganges, is 16 m. long and 8 m. broad, and in the dry season is converted into a pestilential marsh in which rice is sown. The soil of Oude is on the whole the richest in India. It is of various qualities, however, and in some places requires abundant irrigation and laborious tillage. Small nodules called *kankar*, formed of the elements of chalk and oolite, are found in great quantities, and serve a useful purpose in giving sufficient consistency to some of the river banks to keep them in permanent channels. Ridges of them 2 or 3 yards wide intersect the bed of the Goomtee every 5 or 6 miles; and they have formed in different parts of the country hillocks from 70 to 80 feet high. Common salt and saltpetre are obtained from the earth by washing. The climate is generally dry and subject to great extremes of heat and cold, the thermometer sometimes rising to 112° and falling to 28°. November, December, January, and February are the coldest months, and the next four the hottest, a sultry west wind, loaded with fine gray dust, blowing at noon, and ceasing toward evening, or a damp malarious east wind from the swamps of Bengal and Assam occasionally prevailing all day. The power of the hot winds is annually increasing with the diminution of rain. Violent hurricanes and thunder storms are sometimes experienced. The rainy season begins about the middle of June, and lasts from 2 to 4 months. The crops consist principally of wheat, barley, gram, masure (*erum lens*), mustard, rice of remark-

able delicacy and whiteness, millet, maize, joar (*holcus sorghum*), bajra (*holcus stitius*), til (*sesamum orientale*), various kinds of pulse and oil seeds, sugar cane (which is cultivated very unskillfully, though the soil is well adapted to it), opium (which is ill prepared and much adulterated), tobacco, indigo, hemp, various esculent vegetables, and cotton of good quality, though not in large quantity. Groves of excellent fruit trees, among which are the mango, tamarind, and mahua (*bassia latifolia*, from whose flowers is distilled a spirituous liquor, and whose nuts yield an oil which is used instead of butter), are found in different parts of the country, and particularly near Fyzabad, where great care is taken to perpetuate them. The domestic animals of Oude include sheep, goats, cows, bullocks, and tame buffaloes. Among the wild animals are the elephant, tiger, rhinoceros, wolf, hyena, jackal, fox, hare, deer, nylgau, wild hog, porcupine, otter, mongoose, squirrel, rat, muskrat, wild cat, bat, and flying fox. The tigers, wolves, and hyenas cause great destruction of life. Of the numerous varieties of birds, the parrots, which do great damage to the crops, and the kingfishers, which exist in many splendid species, are the most deserving of mention. Reptiles and insects are abundant, and crocodiles are sometimes seen in the larger rivers.—The great bulk of the people are Hindoos, though the dominant race was Mohammedan for many ages before the British annexation. There are probably 100,000 families of Pausies, an aboriginal tribe, generally robbers by hereditary profession, and some of them poisoners. The Brahmins are the most numerous class of the inhabitants, and there are 29 Rajpoot tribes. From these two classes the sepoys of the Bengal army have been mainly recruited. Hindostanee is the language most in use, with a greater admixture of Persian and Arabic and less of Hindee than in the more easterly provinces. The houses of the people are generally mud or unburnt brick, and the walls are carried up 6 or 7 feet above the roof to form a sort of enclosed court for the use of the women. This court is covered during the rains by a light temporary roofing of bamboo and grass. The rooms have no ceilings, and the floors are of earth well packed and smoothed. The most characteristic feature in the social economy of Oude is that of the village communities. Each village forms, as Lord Metcalfe justly termed it, a separate little republic. It has its accountant, public servants, priest, carpenter, smith, washerman, and watchman, who are generally paid by dues claimable from the grain produce of each land owner. The payment of a land tax is one of the oldest institutions of the country. It is levied by a rate upon the land, implements of husbandry, or crops, and is paid to the government officer through the head man of the village. The people value their right of property in the soil above all other worldly goods, and cling to

their ancestral lands with an affection unsurpassed in any other country. The cultivators themselves, as a general rule, own the fields, but in many cases they have been dispossessed by a class of men called *talookdars*. These are persons who farm the revenue of a collection of villages, known as a *talookah*, paying to the government a fixed sum, and exacting from the villagers as much as possible. In some cases the talookdars were hereditary chiefs of Rajpoot tribes, and so became naturally the channels of communication between their people and the government. In others they were originally petty government officials who obtained in various ways the privileges of hereditary farmers of the revenue. They frequently under the native rule laid upon the cultivators imposts which it was impossible for them to pay, and on their delinquency threw them into prison until they executed a deed constituting the talookdars proprietors of the soil. In some instances they obtained such deeds by the more summary process of fire and sword. The dispossessed villager then became the tenant of his oppressor. Some of the more spirited took the law into their own hands, retired into the jungles, and, from committing raids upon all whom the talookdar undertook to settle upon their patrimonial lands, gradually became *dacoits* or professional robbers. At the time of the British occupation the country was infested with such depredators. The East India company in most cases reinstated the villagers in their rights, and held the fraudulent and extorted deeds of conveyance at their proper worth. Where the talookdar could show full and undisputed possession for 12 years, he was acknowledged as proprietor; and where his income was greatly reduced by the withdrawal of villages from his talookah, or other circumstances of hardship appeared, he was allowed 10 per cent. on the government revenue.—The only good road in the province is that from Cawnpore to Lucknow. A railway, however, has been projected, which will pass through Lucknow, and connect it with Benares and Delhi. The province is directly subject to the governor-general in council, and for administrative purposes is divided into 12 *chaklas* or counties, which are subdivided into *pergunnahs* or districts. The principal cities and towns are Lucknow, the capital, Fyzabad, Oude or Ayo-dha, the ancient capital, Roy Bareilly, and Shahabad.—Oude, under the name of Kosala, is supposed by many writers to have been one of the earliest seats of Indian civilization, and Buchanan conjectures its first settlement to have taken place about 1866 B. C. The reign of Rama, the hero of Hindoo romance and the conqueror of Ceylon, is assigned to the 8th century B. C.; and the poem of the *Ramayana*, which narrates his exploits, is supposed by Prof. Wilson to have been written about 800 B. C. Nothing of importance is known of the kingdom before A. D. 1195, when it was conquered and united to the empire of Delhi by Mohammed Bakh-

tiyar Ghilji, a lieutenant of Cuttub-ud-deen, the founder of the Patan or Afghan dynasty. It submitted to Baber (1528) after an obstinate struggle, but frequently revolted against the Mogul sovereigns; and about 1753 Saffdar Jang, nabob vizier of the province, wrested from the emperor Ahmed Shah a grant in perpetuity of Oude and Allahabad, and thus founded an independent dynasty which lasted until the British annexation. His son and successor Sujah-ud-Dowlah became one of the most powerful princes of India, but, having formed an alliance with Meer Cossim against the English, was defeated by the latter at Patna, May 13, 1764, and at Buxar on the 23d of October. In 1765 the British occupied Lucknow and forced Sujah as a condition of peace to transfer the provinces of Corah and Allahabad to the emperor Shah Alum. Three years later the East India company judged it necessary to insist on a reduction of the nabob's military force, which, by a treaty in Nov. 1768, was accordingly limited to 35,000 men. Shah Alum, having in 1773 transferred his claim upon Corah and Allahabad to the Mahrattas, was considered to have forfeited those territories, and the nabob was permitted to resume them on payment of 5,000,000 rupees to the English. With the assistance of English troops, whose services he purchased for £400,000, Sujah next undertook a campaign against the Rohillas, and, having routed them in a decisive battle, April 23, 1774, annexed the greater part of Rohileund to his dominions. His son and successor Azof-ud-Dowlah, a weak and dissolute prince, ceded to the British Benares, Jounpore, and some contiguous districts, in return for which the company agreed to defend him against all his enemies, and to keep a large body of troops in his territory, for whom however he was to pay heavily. This military force was several times augmented, on the ground that the tranquillity of the country and the safety of the surrounding British possessions required it. Immense sums were also demanded from the nabob for the support of an English resident and other English officials, so that the province was drained of its resources and parcelled out among rapacious farmers of the revenue, many of whom in time set themselves up as independent princes. The nabob soon came to regard his white allies as a frightful incubus which no exertion could shake off. He begged to have the troops withdrawn, but the British refused. At length, in Sept. 1781, he signed a treaty at Chunar with the governor-general Warren Hastings, by which he obtained a release from some of his most burdensome engagements on condition of applying the wealth of the two begums or princesses, his mother and grandmother, to the liquidation of his debt to the East India company, which then amounted to £1,400,000. The *jaghires* or lands taken from the begums he was to retain, and their money, of which they were said to have immense sums concealed, was to be

paid over to the English. The most violent and unjustifiable means were used to get possession of the treasure, and the spoliation of the begums of Oude afterward acquired a world-wide celebrity through the denunciations of Burke and Sheridan. From 1777 to 1786 the nabob paid the company £800,000 per annum, beside the expenses of various English officers, one of whom, an agent of the governor-general, received an annual salary of £22,800. In 1787 the subsidy was reduced to £500,000 per annum, but it was increased in 1797 to £550,000, and in 1798 to £760,000, beside which the nabob ceded the fortress of Allahabad and gave £80,000 for its repair and £30,000 for the repair of Futtehghur. In 1801 the pecuniary subsidy was commuted for a cession of various territories, equal to one half of the whole province and yielding an annual revenue of £1,352,000. A loan of £1,000,000 was obtained from the nabob Ghazee-ud-deen Hyder in 1814, and another of the same amount in 1815. These loans were liquidated in 1816 by the transfer to Oude of the Terrai, or marshy tract, formerly belonging to Nepal. In 1819 the nabob with the consent of the East India company formally renounced the nominal allegiance which he had hitherto retained to the Great Mogul, and assumed the title of king. In 1825 he made a loan in perpetuity to the British of £1,000,000, at the unvarying interest of 5 per cent.; in 1829 a loan of £640,000, the interest of which was to be appropriated to the support of certain members of the royal family; and in 1838 a loan of £80,000, the interest of which was to be given to the poor of Lucknow. Nusseer-ud-deen, who reigned from 1827 to 1837, made an effort at first to reform the administration, but soon gave himself up to sensual pleasures. The succession of his uncle Mohammed Ali Shah was contested by the late king's son and the Padshah Begum, Nusseer-ud-deen's principal wife; but Mohammed was supported by the British, and his rivals were soon put down. He was succeeded in 1842 by his son Umjud Ali Shah, under whom the state of the kingdom grew worse and worse. The British urged reforms, and intimated that unless they were effected within a limited time the country would be placed under their management. The king however seems to have had but little power. Under the reign of Saadut Ali (1798-1814) Oude had enjoyed unusual prosperity; but his son Ghazee-ud-deen Hyder (1814-'27) had dissipated the national treasures, and, being withheld by treaty from keeping up a strong army of his own, and but indifferently supported by the British troops, had seen the kingdom parcelled out among a number of petty turbulent princes who defied his authority and proved insuperable obstacles to all measures for improvement. It was now too late to reestablish order, but Umjud Ali succeeded in replenishing the treasury, and on his death in 1847 left about £1,500,000 to his son Wajid Ali, the last king of

Oude. This prince is said to have been more profligate and imbecile than almost any of his predecessors. While he devoted himself to his pleasures the royal revenues dwindled away, and the semi-independent princes grew more and more powerful. They built fortresses, banded their followers into formidable armies, and laid all the surrounding country under contribution. In a communication dated March 15, 1855, addressed to the Indian government by Gen. Outram, British resident at Lucknow, the condition of the country was described as truly deplorable. The people were heavily taxed, though but a small part of the revenue found its way to the public treasury. The revenue collected in 1854 was 12,203,082 rupees (\$6,000,000), of which only 3,600,000 rupees (\$1,800,000) had actually been paid over to the government. There were no courts of law except at the capital, and the judges and all other officers together amounted to only 61, all of whom were venal. The police was corrupt and inefficient. The army numbered 58,904 men, supported at a cost of 4,190,890 rupees; it was rapacious, extortionate, licentious, undisciplined, and cowardly. Suttee, or the burning of widows, was practised, an average of 7 cases occurring annually. The statistics of crime from 1848 to 1854 showed on an average annually 147 dacoitees, 1,578 persons killed and wounded, 78 villages burned and plundered, and 212 persons forcibly carried off. Oppressions and cruelties of every description were continually practised without restraint. The royal government was virtually at an end, when the East India company, in Jan. 1856, caused a treaty to be drawn up, the effect of which would have been to transfer to them the entire administration of the kingdom, while it made provision for the dignity and affluence of the king and his family. This treaty the king refused to sign, whereupon a proclamation was issued by the governor-general in council, Feb. 7, 1856, declaring the deposition of the king of Oude and the absolute annexation of the country to the possessions of the East India company. This measure was not consummated without loud expressions of disapproval on the part of many of the English people and some of the East India officials. The deposition of the king was regarded as a violation of treaty engagements, and as both impolitic and unjust. His majesty was allowed to retain his titles and was granted a liberal pension, but the government refused to make any engagement for the continuation of the same privileges to his descendants. He removed to Calcutta, and fixed his residence at Garden Reach on the outskirts of the city, while the queen mother, accompanied by his majesty's son and brother, visited England with a numerous retinue, arriving in London in Aug. 1856. She was received with great kindness by Queen Victoria, and remained in the country for a considerable time urging her claims for redress, but without avail. She finally died in Paris in 1858. The

talookdars of Oude felt much aggrieved by the regulations of the East India company respecting the tenure of property, and the population in fact never voluntarily submitted to the change of rulers. Hence, when the sepoys mutiny broke out in 1857, the rising in Oude was not confined to the soldiers, but became a popular war for independence. The rebel sepoys concentrated about Lucknow, while the talookdars held themselves in a state of insurrection throughout the province, armed their retainers, and threw themselves into their forts, whence the British frequently could not dislodge them without heavy loss. The complicity of the ex-king was strongly suspected, and he was kept prisoner in Castle William. One of his wives, known as the begum, who resided at Lucknow, put herself at the head of a body of insurgents, coöperated vigorously with Nena Sahib, and is supposed to have escaped to Thibet. The province however was substantially subdued by the end of 1858, and in the spring and summer of 1859 the whole population was disarmed, 1,327 forts being destroyed and 1,867,406 arms of all kinds given up. On Oct. 22 the governor-general made a triumphal entry into Lucknow, and settled the difficulties of the land titles by giving the talookdars a free grant of their estates. (See HINDOSTAN, vol. ix. pp. 190, 191.)—**OUDE**, or **AYODHA**, a town of the preceding province and anciently its capital, is situated on the right bank of the Goggra, 75 m. E. from Lucknow; pop. about 8,000. It adjoins the modern town of Fyzabad, and is now almost deserted. Its principal buildings are the "fort of Hanuman," built in honor of the fabulous monkey god, the auxiliary of Rama, and having an annual revenue of 50,000 rupees settled on it by Sujah-ud-Dowlah; and the ruined "fort of Rama," the mythical hero of the *Ramayana*. Oude is thought to be the most ancient city of India, and according to Buchanan was founded in 1886 B. C. The *Ayeen Akberry* describes it as 200 miles in length.

OUDINOT, **NICOLAS CHARLES**, duke of Reggio, a French marshal, born in Bar-sur-Ornain, April 20, 1767, died in Paris, Sept. 13, 1847. He enlisted at the age of 17, but retired from the army at the desire of his father in 1787. In 1792 he was elected commander of the 3d battalion of the Meuse, attained the rank of colonel by his defense of the castle of Bitche, was made brigadier-general in 1794 for his bravery in the battle of Moorlantern, successfully conducted several operations under Moreau in the campaign of 1796 on the Danube, and became general of division in 1799. He contributed to the success of Masséna in the battle of Zürich, and took part in the siege of Genoa and the battles on the banks of the Mincio. In command of a picked corps of 10,000 grenadiers and voltigeurs, he shared in the campaign of 1805 against Austria, defeating the enemy at Wertingen, entering Vienna, crossing the Danube under a dreadful fire of artillery, and finally

contributing to the victory of Ansterlitz. His services were scarcely less important in the two following campaigns in Prussia and Poland (1806-'7), when he won the battle of Ostrolenka and fought under Napoleon at Friedland. He was rewarded with the title of count and a gift of 1,000,000 francs. In command of the vanguard of the French army in 1809, he distinguished himself so greatly at Pfafenhoffen, Ebersberg, Essling, and Wagram, that he was created marshal of the empire and duke of Reggio, with an income of 100,000 francs. In 1812 he led the 2d corps of the great army that invaded Russia, and so skillfully manoeuvred to protect the crossing of the Beresina, that he was hailed as the "preserver of the army." In the campaign of 1813 he fought at Bautzen, was defeated by Bernadotte at Grossbeeren, and severely wounded at Leipsic. On the fall of the emperor he joined the Bourbons, and faithfully held to their cause during the Hundred Days. Under the 2d restoration he was appointed commander of the national guard of Paris, and in 1823 led the 1st corps of the French army in Spain. Louis Philippe made him chancellor of the legion of honor in 1839, and governor of the Hôtel des Invalides in 1842. A statue was erected in his honor by his native city. During his military career he received no fewer than 35 wounds.—**NICOLAS CHARLES VICTOR**, duke of Reggio, son of the preceding, born in Bar-le-Duc, Nov. 3, 1791, commenced service under Napoleon, became a colonel in 1814, commanded the 1st regiment of horse grenadiers in the royal guard in 1822, and was afterward placed at the head of the school of cavalry at Saumur, but retired for a while on the revolution of 1830. Restored to his rank of brigadier-general in 1835, he went to Africa (where a younger brother had fallen at the head of his regiment), and participated in the expedition of Mascara, but a wound obliged him to return to France. He was then promoted to the rank of general of division. He was twice elected to the chamber of deputies. After the revolution of 1848 he held a seat in both the constituent and the legislative assemblies. He was appointed to command the French army sent against the Roman republic, landed at Civita Vecchia April 25, 1849, and took possession of Rome July 8. Returning to France, he reappeared in his seat in the legislative assembly, and opposed the policy of the president. On Dec. 2, 1851, he was one of the members of the assembly who met in the hall of the 10th district to protest against the *coup d'état*, and was arrested and for a few days held prisoner in the castle of Vincennes. Since then he has retired to private life. Several essays of his upon military matters have attracted attention. He was one of the founders of the *Spectateur militaire*, a periodical to which he is still an occasional contributor.

OUGHTRED, **WILLIAM**, an English mathematician and divine, born in Eton, Buckinghamshire, in 1573, died Jan. 30, 1660. He was

educated at Eton, and at King's college, Cambridge, where he invented while an undergraduate "an easy method of geometrical dialling." Having received holy orders, he was presented to the rectory of Aldbury, near Guildford, in 1603, and in 1628 was tutor to the son of the earl of Arundel. He was called the "prince of mathematicians," and left numerous works.

OUISTITI. See MARMOSSET.

OUNOE (*felis uncia*, Buffon; *leopardus uncia*, Gray), a medium-sized cat of the old world, smaller than the leopard, inhabiting the mountainous regions of Asia. Buffon distinguishes it from the panther by its smaller size (the length of the body being only 3½ feet), its longer and shaggy hair, and its tail nearly as long as the body. The ground color is whitish gray on the back and sides, without tint of fulvous, and whiter below; the body is marked by blackish spots, sometimes forming irregular circles, the limbs simply spotted, and the tail ringed. It is a very active animal and an expert climber, preying upon rodents and the smaller ruminants. Ouvier and others regard it as a variety of the panther, the last also being considered the same as the leopard. Hamilton Smith considers it distinct, and Gray describes it as a species in the catalogue of the British museum. Its size, markings, and habitat seem sufficient to entitle it to rank as a true species.

OUSLEY, GIDEON, an Irish clergyman, born in Dunmore, Galway, in 1762, died May 14, 1839. He became a member of the Wesleyan church, and after laboring 20 years as a local preacher was appointed in 1799, missionary to the Irish. He entered upon his duties just at the close of the great rebellion, and from the excited state of the Catholic population was subjected to many trials, being frequently assaulted while preaching in the streets. He was regarded as the most efficient and successful Irish missionary ever employed by the Wesleyans, preaching often 5 times a day in English and Irish. He left various works on the Roman Catholic controversy, the best known of which is his "Old Christianity, against Papal Novelties."

OUSELY, SIR WILLIAM, an English orientalist, born in Monmouthshire in 1771, died in 1842. In 1787 he went to Paris to study French, and the following year became cornet in a regiment of British dragoons stationed in Ireland. Devoting all his leisure to the oriental languages, he left the military service after the campaign of 1794, and went to the university of Leyden. In 1795 he published his "Persian Miscellanies." Afterward he went to London, received various complimentary distinctions from the universities and learned societies, and accompanied as private secretary his brother, Sir Gore Ousely, the ambassador to the Persian court. Among his works are: "Oriental Collections" (3 vols. 4to., 1797); "Observations on some Medals and

Gems, bearing Inscriptions in the Pahlavi or Ancient Persian character" (4to., 1801); "An Abstract of the Persian Translation of the Geography written in Arabic by Ibn Haukal;" a descriptive catalogue of his collection of Persian, Arabic, and Turkish manuscripts, and "Anecdotes from Oriental Bibliography" (1827); and another catalogue of his oriental manuscripts in 1831. An account of his travels in Persia was published in 1819-'22 (8 vols. 4to.).

OUTAGAMIE, an E. co. of Wis., intersected by Neenah, Wolf, and Embarras rivers; area, 684 sq. m.; pop. in 1855, 2,716. Its surface is diversified and covered with great forests, which yield large quantities of lumber. It was separated from Brown co. in 1850, and is not included in the census of that year.

OUTLAWRY (law Latin *utlagaria*, *utlagatio*, from *utlagatus*, *exlex*; Saxon, *utlaugh*, *utlaughe*), the process by which one is excluded from the protection of the law, partly in respect to his property, and partly in respect to his person. When a party defendant, after formal and proper summons, refuses to appear before a court of competent jurisdiction, his contumacy is in fact nothing else than rebellion against the organic law of the state; he sets at defiance the authority of the society of which he is a member, and, whether his conduct be construed as an admission of guilt, or more properly as a mere contempt, he certainly cannot complain if those who are intrusted with the maintenance of the social order and welfare declare that he has forfeited the benefits and privileges of the law to which he refuses to submit. The outlaw, says Bracton, forfeits home and country, and becomes an exile. Anciently he was known by another name, to wit, *frendlesman*, as it seems, because he forfeited his friends; for if any of them rendered him any assistance, they suffered the same punishment as the outlaw himself, losing like him both their goods and their life, unless the king of his grace spared them. From the time one was outlawed he was said anciently to bear a wolf's head (*caput lupinum gerere*); and it is usually stated, as if on the authority of Bracton, that an outlaw might be killed with the same impunity as a wolf. But this author says plainly, that one might take the outlaw's life only when he resisted being taken, or endeavored to escape. After his capture, his death or life rested in the hands of the king alone. All males above the age of 12 years might suffer outlawry, because at that age they were all sworn and enrolled in the decennary, and were thus within the law of the realm. Women were "waived," not outlawed, because they were not thus sworn. They therefore could not be excluded from the benefit of the law, but were abandoned or disregarded by it.—Outlawry was pronounced originally only in cases of treason or felony. Next it was extended to trespasses of a flagrant character. But properly it was limited to those processes in which a *capias* lay, that is,

a writ or warrant to take the person of the defendant. In all actions of trespass *et et armis* this *capias* lay at common law, and consequently also, in proper cases, outlawry. In actions of debt, detinue, covenant, and such others as are founded upon mere negligence or laches, *capias* did not lie at common law, and therefore outlawry was impossible, until it was introduced by act of parliament. A distinction was made, in respect to the consequences of outlawry, between criminal and civil cases. In the former, sentence of outlawry operated as a conviction of the offence itself with which the accused was charged. In treasons and felonies therefore he suffered corruption of blood, and forfeiture of all his estate, real as well as personal. In civil cases the ultimate object of the outlawry was to secure access to the defendant's property. His failure to appear was, accordingly, not accounted a confession of the matter charged; but as a contempt, it deserved and drew after it a forfeiture of personal property and loss of the profits of lands so long as the outlawry lasted. An outlaw will not be heard in the courts where he seeks to originate a legal right, and his adversary may plead the outlaw's disability in bar or in abatement of his suit. Indeed, he cannot appear in court for any other purpose than to reverse his outlawry. He cannot be a juror, for he is not an unimpeached citizen, *liber et legalis homo*; but if he was outlawed in a civil action, he may be an heir or a witness. In England, outlawry is declared after three successive writs of summons to the defendant, and after he has been called by the sheriff in five different courts. The judgment of outlawry may be reversed by writ of error or upon motion in the courts, and after reversal the party may be put to plead to the original process.—The process of outlawry is rare in the United States. In some states it has never been known. In Pennsylvania it is retained in treason, robbery, burglary, and sodomy; in New York, in treason alone. In both these states outlawry in civil actions has been expressly abolished, and it may be said to have no actual existence in any.

OUTRAM, SIR JAMES, a British soldier, born at Butterley Hall, Derbyshire, Jan. 29, 1808. He is the son of Benjamin Outram, an eminent civil engineer, was educated in Scotland, of which country his mother was a native, and after studying with distinction at Marischal college, Aberdeen, went out to Bombay in 1819, as a cadet in the military service of the East India company. He was posted to the 28d regiment of Bombay native infantry, of which he soon became adjutant, and, having distinguished himself by a brilliant and successful attack upon an insurgent stronghold in Candish, was selected by the governor, Mountstuart Elphinstone, to undertake a mission to the ferocious Bheel tribes. His first exploit was to beat them in battle; his next to organize them into an irregular military corps, hoping

that these indomitable marauders might be civilized by turning their warlike spirit to some legitimate purpose. The result of a short trial fully justified his anticipations, and peace being restored to the Bheel country he was sent into Guzerat to subdue the rebel chiefs of the Mye-Caunta. This he effected by similar measures, defeating them first and conciliating them afterward. When the war with Afghanistan broke out, he volunteered his services, and was appointed honorary aide-de-camp to Sir John Keane, rendering valuable assistance throughout the campaign. He played a conspicuous part in the capture of the Beloochee stronghold of Kelat (1840), and, disguised as a native devotee, carried the news of its fall a week's journey through the enemy's country to Kurrachee, where he took ship for Bombay. For his services on this occasion he received the brevet rank of major, and was appointed political agent in Lower Sind, where he not only upheld the British arms, but gained the affection of the native chiefs. When Sir Charles Napier undertook the conquest of Sind, Outram was resident at Hyderabad, and endeavored to avert a collision between the ameers and the British. The princes treated him courteously, but the soldiers growing furious and attacking the residency, he defended himself with a small escort, and finally effected an orderly though dangerous retreat. He condemned the whole war "as most tyrannical, positive robbery," and was consequently involved in an acrimonious controversy with Sir Charles Napier. After a short visit to England, he was employed against the rebels in the South Mahratta country, organized a light irregular force, and, to use the words of Sir Henry Lawrence, "his very advanced guard drove before them the half-armed rabble that had kept three brigades at bay." In 1845 Outram (now a colonel) was appointed resident at Sattara, and in 1847 resident at Baroda. In the latter station his zeal for the suppression of certain corrupt practices, in which his language was not always moderate or prudent, brought him into disfavor with the Bombay government, and returning to England he plunged into a paper warfare by which he secured from the first the sympathy of the public, and finally the approval of the court of directors. In 1854 he was appointed political resident at Lucknow, and after the annexation of Oude in the early part of 1856 again sailed for Europe, was made civil knight commander of the bath, and on the outbreak of the Persian war was appointed commander-in-chief of the British forces in Persia, with the temporary rank of lieutenant-general, his actual rank at this time being that of major-general. Reaching Bushire, where the first division was already encamped, about the end of Jan. 1857, he defeated the Persians at Borasjoon, Feb. 5, and Koosh-aub, Feb. 8, and took Mohammerah, March 26, soon after which news arrived that peace had been signed between England and Persia. Returning to India, which was then in

the midst of the sepoy rebellion, Outram was appointed to the military command of the Cawnpore and Dinapore divisions. His first effort was to relieve Gen. Havelock at Cawnpore, and this effected (Sept. 15) to march with him to Lucknow; but in consideration of Havelock's previous exertions to assist the garrison at the latter place, he chivalrously refused to take from him the command of the relieving force, and accompanied it as a volunteer. Entering Lucknow Sept. 25, he conducted the defence of the residency until the rescue by Sir Colin Campbell, Nov. 19, when he occupied a fort called the Alumbagh, about 4 m. from the city, and during the next few months several times defeated the rebels with great slaughter. He cooperated with Campbell in the final siege and capture of Lucknow in March, and in the capacity of chief civil commissioner immediately applied himself to restore order in the province. He was soon summoned to Calcutta as a member of the supreme council. In the summer of 1860, his health being much broken, he returned home, and retired to private life. In 1857 he received the military decoration of the grand cross of the bath for his services in Persia, was created a baronet of the United Kingdom in 1858, became lieutenant-general in the same year, and in Dec. 1860 was presented by the corporation of London with the freedom of the city and a sword.

OUZEL, a genus of birds of the thrush family, *hydrobata* (Vieill.) or *cinclus* (Bechst.). The bill is without bristles at the base, moderate, slender, slightly bent upward, with culmen nearly straight, and curved and notched tip; the frontal plumes come as far as the opening of the nostrils; wings moderate and rounded, the 1st quill spurious and the 2d rather shorter than the 3d and 4th, which are longest; tail very short and nearly even; tarsi as long as middle toe, covered in front with an entire scale; feet robust, with toes moderate, the outer the longest, and united at base; claws long, curved, and sharp. About half a dozen species are described in America, Europe, and Asia. The American water ouzel or dipper (*H. Mexicana*, Baird; *O. Americanus*, Swains.) is about $7\frac{1}{4}$ inches long, with an extent of wings of $10\frac{1}{2}$; the color above is dark plumbeous, paler beneath; head and neck with a sooty brown tinge; a concealed white spot above the front of the eye, and sometimes below it; in young birds the feathers beneath, the wing coverts, and lesser quills are edged with grayish white; it inhabits the vicinity of clear rapid streams in the Rocky mountains from British America to Mexico. The European ouzel or dipper (*H. cinclus*, Vieill.; *O. aquaticus*, Bechst.) is of about the same size, with the head and hind neck dark brown, the upper parts dark gray with broad black edgings, throat and fore neck white, and breast brownish red; the female with less deep tints; the young grayish above, with black edgings. A similar species (*H. Asiatica*, Swains.) is found in northern

Asia.—The form of the ouzels is compact, and the motions and attitudes are like those of the wrens. Their habits are very peculiar, and have been accurately described by Macgillivray in Great Britain from actual observation; they are found singly or in pairs in mountainous districts on the borders of streams; they seek their food under water, not plunging superficially like the kingfisher or the fish hawk, nor going under from the surface like the ducks, but darting boldly into the water from the wing, diving to the bottom, and swimming and running about there with great rapidity, in search of aquatic insects, larvae, and mollusks, on which they feed. The ouzel is said also to devour the spawn and fry of fishes, and on this account, though probably without reason, is very generally persecuted by anglers and gamekeepers; its progression under water is by the action of the wings, as in many web-footed birds; it remains submerged for a minute or two, swimming well, rising buoyantly to the surface, and able to dive again without rising on the wing. The flight is direct and rapid; it is in the habit of perching on stones in the middle of streams, constantly moving the tail up and down; it is a very poor walker; when wounded, it plunges under water and escapes to the shore, struggling to the last when taken. The note is a gentle warble, short and lively, but not resembling the full song of the proper thrushes. It begins to make a nest about the middle of spring, of moss and leaves, on the bank of a stream, among the roots of a tree overhanging the water, in the crevice of a rock, or in a hole in a bridge, dam, or wall; it is of large size, arched over, and compactly built; the eggs are 5 or 6, pure white, somewhat smaller than those of the song thrush. This genus is considered intermediate between the ant-thrushes and thrushes proper; its short and dense plumage, short wings and tail, and bill, are admirably adapted for making its way under water, and seizing and detaching its food from submerged stones. According to Macgillivray, the genus forms a connecting link between the slender-billed land birds and the diving water birds, as the kingfisher seems to unite the former with the plunging birds of the same order.—The name of ring ouzel is given to the European thrush (*turdus torquatus*, Linn.) from its having a broad white crescent across the black of the breast; and the blackbird (*T. merula*, Linn.) is often also called ouzel in Great Britain.

OVEN BIRD, the popular name given to a group of tenuirostral birds of the sub-family *furnarina* and the family of creepers, inhabiting the warm parts of South America and the West Indies. In the typical genus *furnarius* (Vieill.) the bill is moderate, slender, and slightly curved; wings and tail moderate, and tarsi long. The red oven bird (*F. rufus*, Vieill.), called *hornero* in La Plata, is about 6 inches long, reddish above and white below; it is seen generally in pairs, both in bushy and open

places and near human habitations, running rapidly or making short flights from bush to bush in search of insects, especially *coleoptera*; it will also eat seeds; the note is loud and shrill. The nest is placed in an exposed situation on a tree, paling, window sill, or even in the interior of a house; both sexes work at it, alternately bringing a lump of clay, or piece of straw and twig, which they fashion into a dome-shaped structure like a baker's oven, 6 or 8 inches in diameter and with walls about an inch thick; the opening is on the side, and near it is a partition reaching nearly to the roof, behind which is an inner chamber in which the eggs, 4 or 5, are deposited on feathers and soft grass. The genus *cinclodes* (Gray) frequents the sea beach, and may often be seen walking on the masses of floating sea weed near the shore; some occasionally wander inland, and even to the height of 8,000 feet on the Cordilleras; their food consists of insects, small crustaceans and mollusks, and seeds. Other genera are *lochmias* (Swains.), of Brazil; *enicornis* (Gray), in dry regions of Patagonia and the barren Cordilleras; *limnornis* (Gould), on the reedy borders of South American lakes, climbing vertically along the stems; *geositta* (Swains.), on the open sandy plains; and *cinclocerthia* (Gray), of the West Indies. The prevailing colors are red and brown, varied with black and white.

OVERBECK, FREDERICK, a German painter, born in Lübeck, July 8, 1789. He commenced his artistic education in Vienna in 1806, and in 1810 repaired to Rome, where he was thrown into the society of a number of young compatriots, who had become convinced that a return to the truth and simplicity of the early Italian masters could alone effect a healthful regeneration of art. Overbeck, who was of a devout and impressible nature, soon became the soul of the movement, and, aided by Cornelius, Veit, Schadow, Pforr, Schnorr, and others, as well as by the hints afforded by Schlegel and other sympathizers, he laid the foundation of a new and remarkable school of painting. A Madonna painted in 1811 first brought him into notice in Rome, and he soon proved his claim to be considered the head of his school by the frescoes of "Joseph sold into Captivity by his Brethren" and the "Seven Years of Famine," painted in the villa of the Prussian consul, M. Bartholdy, in which the young German artists executed their first important works. Overbeck now gradually restricted himself to works of an exclusively devotional character, which he strove to imbue with the religio-mystic feeling of an earlier epoch in art. In like manner he adopted the theological views of his artistic prototypes, and in 1814, in company with several of his associates, abjured Lutheranism and embraced the Roman Catholic faith. His life has since been passed almost entirely in Rome in the practice of his art. At first he was surrounded by a band of enthusiastic disciples, but by degrees his followers either died, or were

enticed by the more vigorous and romantic style into which the new German school expanded, to renounce the limited range of subjects and the severe, almost ascetic, style of their master. Their places have not been readily supplied, and Overbeck now labors in his vocation almost alone, but with not less enthusiasm than when he commenced his career in Rome 50 years ago. Of his works in fresco, the revival of which his example greatly aided, the most remarkable are a series of 5 representing subjects from Tasso's *Gerusalemme liberata*, executed in 1817 in the villa Massimi in Rome, and the "Vision of St. Francis" painted for the church of the Madonna degli Angioli near Assisi, the latter of which is considered a remarkable exposition of the principles of Christian art as understood by him. The picture which first gave him a European reputation was the "Entry of Christ into Jerusalem," completed in 1824 for the Marienkirche in Lübeck, and which is well known by engravings. Other works by him of a scriptural character are "Christ bearing the Cross," "The Child Christ in the Temple," "Christ blessing Little Children" (also well known through the engravings), "The Raising of Lazarus," "Christ raising the Daughter of Jairus," "Christ on the Mount of Olives," "St. John preaching in the Wilderness," "Moses and the Daughter of Jethro at the Well," "Gathering the Manna," "Hagar in the Desert," and the "Ascent of Elijah." His numerous "Holy Families" and *Pietas*, "Marriage of the Virgin," "Virgin with the Lily," "Three Kings," "St. Elizabeth," "Assumption of the Virgin," &c., are examples of his manner of illustrating the traditions of the church. His masterpiece perhaps is the elaborate composition in the Städelische institute at Frankfurt-on-the-Main, representing the triumph of Christianity in the arts, of which the upper compartment is occupied by Christ in the act of blessing, the Virgin, and a crowd of prophets, saints, and apostles, while below are the representatives of music, architecture, sculpture, painting, &c., the heads in most cases being portraits. As a designer in charcoal and chalk, he is perhaps more generally known than by his paintings; and engravings of his "Passion of our Lord," "Forty Illustrations from the Gospels," and similar series of drawings have been executed by Ruscheweyh, Schäfer, Amaler, Keller, Koch, and other German artists. He has also designed a remarkable series of cartoons to be executed in fresco in the chapel of the banker Torlonia's villa at Castel-Gandolfo. Occasionally he has attempted allegorical figures, such as his "Germania" and "Italia."

OVERBURY, SIR THOMAS, an English courtier and author, born at Compton-Scorfen, Warwickshire, in 1581, died in the tower of London, Sept. 15, 1613. He was graduated at Oxford in 1598, and entered of the Middle Temple, but he soon forsook the law to travel on the continent. In 1601 he went to Edin-

burgh, where he formed an acquaintance with Robert Carr, a sewer or page in the service of the earl of Dunbar. Carr was illiterate, but handsome and amorous. Overbury added to the refinement of gentle breeding the accomplishments of a good education. He became Carr's intimate friend and adviser, wrote his love letters, and held all his secrets; and when Carr removed to London and became the chief favorite of James I., Overbury shared his good fortune, and in 1608 was knighted. In 1609 he visited France and the Netherlands, and wrote a volume of "Observations upon the State of the Seventeen Provinces" (1626). Vain, arrogant, and presuming, he was expelled from court for an insult to the queen; but his patron, who had been created Viscount Rochester, procured his recall. Rochester was now engaged in an intrigue with the lady Frances Howard, daughter of the lord chamberlain Suffolk and wife of the earl of Essex. Overbury assisted him with his pen to win the love of the profligate countess; but when it was proposed, with the approbation of the king and the lady's father and uncle, to procure a divorce and marry her to Rochester, he interposed objections, denounced the lady as a strumpet, wrote his poem of "The Wife" to dissuade his patron from the project, and declared that he could and would throw an insuperable obstacle in the way of their union. The countess in her rage offered £1,000 to Sir David Wood to take Overbury's life in a duel; but her uncle Northampton, who was jealous of his influence, proposed a safer plan to get him out of the way, and caused a foreign embassy to be offered him, which Rochester persuaded him to refuse. His refusal was declared a contempt of the king's commands, and on April 21, 1613, he was committed to the tower. Here he was confined in one of the closest dungeons and debarred from all communication with his friends. The lieutenant-governor was removed to make place for Sir Jervis Elwes, a creature of Suffolk's, and a man named Weston was employed by the countess to be the prisoner's sole attendant. In 5 months Overbury died after great suffering, and with every indication of having been slowly poisoned. The murderers were successful for a time in defying public suspicion. The divorce was obtained, and Rochester, now raised to the dignity of earl of Somerset, was married to the countess. But two years later, when Villiers had become the royal favorite, Winwood the secretary laid before the king some evidence which had been collected by Trumbull, the British ambassador in the Netherlands, and Somerset and his wife were arrested. James committed the investigation to Sir Edward Coke. The minor conspirators, Weston, Elwes, Franklin, an apothecary who furnished the poison, and a woman named Turner, were convicted and executed. The countess, on being placed at the bar of the house of lords (May 24, 1616), pleaded guilty, and received

judgment of death; and her husband after a long trial was sentenced to the same penalty; but both were pardoned a few days afterward. Somerset refused to accept less than a reversal of judgment, but in 1624 he petitioned for what he had refused, and received also a pension of £4,000. The fate of Overbury has never been satisfactorily explained. James is not free from a suspicion of complicity in his death, but what motive he could have for wishing it can only be a matter of the wildest conjecture.—Overbury wrote, beside the works already mentioned, a series of "Characters" and "Newes from any whence, or Old Truths under a Supposal of Novelty" (1614); "The First and Second Part of the Remedy of Love" (1620), a paraphrase from Ovid; and "Crumms fallen from King James's Table, or his Table Talk" (1715). His style is somewhat overstrained, but he displays wit, ingenuity, and great knowledge of the world and of character. There is a complete edition of his works, with a life by E. F. Rimbault, in Mr. Russell Smith's "Library of Old Authors" (London, 1856).

OVERSTONE, SAMUEL JONES LOYD, baron, a British financier, son of the banker Lewis Lloyd, born in London, Sept. 25, 1796. He was educated at Eton, and at Trinity college, Cambridge, and in 1819 entered parliament as member for Hythe, retaining his seat until 1826. About the same time he became a partner in the paternal banking house of Jones, Lloyd, and co., which his commercial sagacity and intimate knowledge of business caused to rank among the first in Great Britain. Such was his reputation as a financier that he was on various occasions consulted by the government on measures connected with the commerce of the country; and it has been understood that some of the most important portions of Sir Robert Peel's bank charter act were suggested by him. In 1850 he was elevated to the peerage as Baron Overstone and Fotheringay of Northamptonshire. He has long been considered a leading authority on banking and commercial matters, and both in his legislative capacity and through the columns of the press has given publicity to his views. A collection of his papers has recently been published in 2 vols. for private circulation.

OVERTON, a N. co. of Tenn., bordering on Ky., drained by Obie's or Obed's river, a branch of the Cumberland, navigable by steamboats for 60 m. in the county; area, 530 sq. m.; pop. in 1850, 11,211, of whom 1,065 were slaves. The surface in some parts is mountainous, and the soil generally fertile. The productions in 1850 were 622,485 bushels of Indian corn, 63,824 of oats, 86,791 of sweet potatoes, 63,753 of tobacco, and 104,885 of butter. There were 15 grist mills, 2 saw mills, 8 tanneries, 23 churches, and 1,738 pupils attending public schools. Capital, Livingston.

OVERTURE (It. *overture*; Fr. *ouverture*), a species of introductory symphony prefixed to an opera or oratorio, of which it is intended to

present an epitome or characteristic sketch. Its invention is ascribed to the French composer Lully, and in the oldest overtures the fugue, preceded by a slow movement in $\frac{4}{4}$ time and closing in the dominant, was the prominent feature. In this style were written the overtures of Handel and many of his contemporaries. The overtures of modern composers frequently contain snatches of the leading airs of the opera. Such compositions are sometimes called programme overtures. Overtures are occasionally written on the themes afforded by poetical or dramatic works, as Beethoven's overture to Goethe's "Egmont."

OVERWEG, ADOLF, a German geologist and explorer, born in Hamburg, July 24, 1823, died Sept. 27, 1852, in Maduari, central Africa, whither he had accompanied the expedition of Richardson and Barth. (See BARTH, HEINRICH.)

OVERYSSEL, or OVERIJSSSEL, a province of the Netherlands, bounded N. by Friesland and Drenthe, E. by Hanover and Westphalia, S. and S. W. by Gelderland, and W. by the Zuyder Zee; area, 1,282 sq. m.; pop. in 1860, 224,488. The surface is generally low, but diversified by a few small hills locally called mountains, and in the E. part the soil is principally marshy. Large peat moors are found here, and in other places there are sandy heaths. The best land is near the Yssel, which enters the province from Gelderland, forming part of the boundary between the two provinces. The other chief rivers are the Vechte, Schiepsbeek, Zwart-water, and Linde. The Zwart-water and Yssel are united by a canal. The province contains several small lakes. The principal productions are rye, buckwheat, hemp, fruits, cattle, and peat; and the most important manufactures are linen and cotton goods, wicker ware, mats, and iron. The pasture lands are particularly rich, and cattle breeding and peat digging are the most important branches of industry. Considerable attention is also given to the fisheries and to bee keeping. The climate is moist and unhealthy. Zwolle, the capital, Deventer, and Kampen are the chief towns.

OVID (PUBLIUS OVIDIUS NASO), a Roman poet, born in Sulmo in the country of the Peligni, March 20, 48 B. C., died in Tomi on the Euxine S. of the mouth of the Danube, A. D. 18. He was of an ancient equestrian family, and was educated for the bar; but his taste for poetry interfered so seriously with his professional studies, that the elder Seneca, who had seen one of his rhetorical exercises, describes it as *solutum carmen* rather than an argumentative discourse. His father, believing that poverty was the lot of poets, endeavored in vain to wean him from these tastes, but subsequently allowed Ovid to follow the bent of his inclinations. He accordingly finished his education in Athens, and after travelling in Asia and Sicily returned to Rome, where, though it is doubtful if he ever practised the law, he discharged the functions of judge in

several of the minor courts, and was finally promoted to be one of the *decemviri*, who presided over the court of the *centumviri*. The poets Maecius, Propertius, Ponticus, and Bassus were among his intimate friends, and he had frequent opportunities of hearing Horace recite his compositions. Virgil he saw but once, and Tibullus he knew, but not intimately. He was thrice married, his first wife being quickly put aside for unfaithfulness, and his second because she was irksome to the poet, who was then enamored of a mistress celebrated by him under the name of Corinna. According to Sidonius Apollinaris, this was Julia, the profligate daughter of the emperor Augustus. She was undoubtedly a married woman of high rank, and may be said to have incited Ovid to his first successful attempts at elegiac poetry, the series called the *Amores*, subsequently published by him in a second edition under the title of *Amorum Libri III.*, being the result of his intimacy with Corinna. At about the age of 30 he married his 8d wife, with whom he appears to have lived happily, and by whom he had one child, a daughter. His amours thenceforth, if not entirely discontinued, were conducted with some regard for propriety; and the friendship of Atticus and other eminent men, the regard and favor of the imperial family, and his poetical reputation, greatly enhanced by the production of his *Epistole Heroidum*, his *Ars Amatoria* or *De Arte Amandi* and *Remedia Amoris*, his tragedy of *Medea*, now lost, and other pieces, rendered this portion of his life easy and agreeable. This tranquil existence was suddenly interrupted in A. D. 8 by an imperial edict commanding the poet to transport himself at once to Tomi, a town on the Euxine in the country of the Getae, and on the very confines of the empire. No reason for this banishment, which was for life, though without the loss of citizenship or property, was assigned, beyond his having published his poem on the art of love; but it has been justly supposed that so severe a punishment would not have been inflicted for an offence of this nature, committed 10 years previous, unless it had been accompanied by another of greater heinousness. The publication of the *Ars Amatoria* is consequently regarded as a mere pretext on the part of Augustus, the motive for whose displeasure has long exercised the ingenuity of scholars. The poet himself hints at some "error," which however he never mentions, as the real cause of his punishment. His alleged intrigue with the emperor's daughter Julia has been presumed to be the "error" in question; but the fact that she was exiled more than 10 years before Ovid is a sufficient refutation of this opinion. Others have maintained that it was the younger Julia with whom he had an amour; and notwithstanding the disparity in their years, the coincidence of his banishment with hers gives ground for the idea. In the latter part of December Ovid left Rome for ever, and after a journey of nearly a year reached the inhospitable

table spot to which he was banished. The people among whom his lot was cast were scarcely less rude than their climate. The constant alarms excited by the incursions of barbarian hordes, the anxiety for his health and safety, and the absence of friends and family, rendered his existence wretched in the extreme; and he never ceased to offer affecting but unavailing supplications for the imperial clemency. The pursuit of literature afforded the chief alleviation to his misfortunes; and, beside applying the finishing touches to his *Fusti*, he wrote during his exile the *Tristia*, a record chiefly of his sufferings and appeals for pardon; the letters to his wife and friends *Ex Ponto*, very similar in style and substance to the *Tristia*; the *Ibis*, a satire; and some other pieces not sufficiently substantiated at the present day. His modest bearing and affable manners won upon the simple inhabitants of Tomi, among whom he rendered himself exceedingly popular by publicly reciting some poems composed in the Getic language, which he had succeeded in mastering. He died in the 10th year of his exile, worn out by grief, anxiety, and the rigor of the climate. The poems above mentioned, with the exception of *Medea*, are composed in elegiac metre, which Ovid wrote with more facility and elegance than any of his contemporaries. The *Fusti*, a sort of poetical Roman calendar with its appropriate festivals and mythology, of which the last 6 books are lost, is considered the best of them, and in melody of rhythm, epigrammatic brevity and point, and skilful antithesis, is a model of technical excellence. His chief work however, both in bulk and pretensions, was his *Metamorphoses*, in 15 books, composed previous to his exile, and burned by him during the hurry of his departure from Rome, but of which copies had been previously taken by his friends. It is written in heroic verse, and never received the final corrections of its author; but in spite of frequent prolixity, and an over indulgence in trite images and trifling conceits, the result of a remarkable facility of composition, it is impossible to resist the charm of the narrative, which, as the title denotes, includes such legends of mythology as involved a transformation, or to overlook the poetic beauties scattered with a lavish hand throughout the work. His poems written in exile, though not less skilfully versified, are far inferior in poetic merit. Schiller characterizes them as the offspring of necessity rather than of inspiration, but Gibbon has well pointed out their value as illustrations of the human mind under singular and affecting circumstances. The lost tragedy, *Medea*, of which but two lines remain, was, according to the testimony of antiquity, the poet's masterpiece.—Of the numerous complete editions of Ovid, the more remarkable are the *editio princeps* by Balthazar Azoguidi (3 fols. fol., Bologna, 1471), the Aldine edition (3 vols. 8vo., Venice, 1502), the Elzevir edition by Heinsius (3 vols. 12mo., Ley-

den, 1629), the Delphin edition (4 vols. 4to., Lyons, 1689), Burmann's edition, esteemed the best (4 vols. 4to., Amsterdam, 1727), and Burmann's text with Bentley's MS. emendations (5 vols. 8vo., Oxford, 1825). There are also a number of editions of separate pieces. Of translations of his works nearly every European language possesses an abundance. The most esteemed metrical version of the *Metamorphoses* in English is that "translated by the most eminent hands," including Dryden, Addison, Congreve, Rowe, Gay, Ambrose Phillips, and others (fol., London, 1717), of which many editions have appeared. The version of George Sandys (fol., London, 1636), translated on the banks of James river in Virginia, deserves mention as the first work of any note composed in America. The *Ars Amatoria* and *Heroides* have in like manner been versified by several of the preceding translators, and Marlowe and others have also tried their hands upon them. Sir Thomas Overbury paraphrased the *Remedia Amoris*, and a translation of the *Fusti* by J. Gower was published at Cambridge in 1640. A literal prose translation of all the poems, by H. T. Riley, forms 8 vols. of Bohn's "Classical Library."

OVIEDO, a N. province of Spain, nearly identical with the ancient principality of Asturias, bounded N. by the bay of Biscay, E. by the province of Santander, S. by Leon, and W. by Lugo; extreme length 147 m., breadth 53 m.; area, 8,674 sq. m.; pop. in 1851, 555,215. (See ASTURIAS).—OVIEDO, the capital of the province, is situated upon rising ground near the N. bank of the river Nalon, about 20 m. S. S. W. from the small port of Gijon on the bay of Biscay, and 245 m. N. N. W. from Madrid; pop. in 1850, 10,500. It is a fine town, and has an admirable Gothic cathedral built in the 14th century, and a university with a library of 12,000 volumes. There are 11 public fountains supplied with water brought into the town by an aqueduct supported upon 41 arches. Oviedo is the see of a bishop. It was pillaged by Ney's troops in 1809, and afterward by those of Bonnet.

OVIEDO Y VALDES, GONZALO FERNANDEZ DE, a Spanish chronicler, born in Madrid in 1478, died in Valladolid in 1557. He was of noble descent, spent several years of his boyhood at court, and was present in the closing campaigns of the Moorish war. In 1514 he was sent to San Domingo as supervisor of gold smeltings, and passed there almost the whole of his subsequent life, holding various offices and occasionally revisiting Spain. Having been appointed historiographer of the Indies, with authority to demand from the Spanish American governors whatever documents he needed, he composed a "Natural and General History of the Indies" in 50 books, 21 of which were published in Seville in 1585, and a complete edition is now in progress at Madrid. This work was denounced by Las Casas as little better than fabulous; but Las Casas was a bitter enemy of

the author, whom he accused of rapacity and cruelty in his government. In his 79th year Oviedo finished his valuable work entitled *Las quinquagenas*, in which he gives under the form of dialogues a full, gossipping, and anecdotal account of all the principal persons of Spain of his time. It is still in MS. in the royal library at Madrid. He also wrote chronicles of Ferdinand and Isabella and Charles V.; and a life of Cardinal Ximenes is attributed to him.

OWEGO, a township and the capital of Tioga co., N. Y., on the Susquehanna river at the mouth of Owego creek; pop. of the township in 1855, 8,328; of the village, 8,041. It is the centre of a rich and extensive agricultural and lumber district, and has an active and increasing trade. It contains manufactories of steam engines, boilers, and machinery, and flour, plaster, and woollen mills, the Owego academy, a female seminary, 3 banks, 2 newspaper offices, and 18 churches, viz.: 1 Baptist, 1 Congregational, 1 Episcopal, 5 Methodist, 2 Presbyterian, 1 Roman Catholic, 1 union, and 1 Wesleyan Methodist. The Susquehanna is here crossed by a bridge 240 feet long. It is on the line of the New York and Erie railroad, and is connected with Ithaca by the Cayuga and Susquehanna railroad.

OWEN. I. A N. co. of Ky., bounded W. by the Kentucky river, and N. by Eagle creek; area, about 300 sq. m.; pop. in 1850, 10,444, of whom 1,514 were slaves. It has an undulating surface and a fertile soil. The productions in 1850 were 682,870 bushels of Indian corn, 22,794 of wheat, 46,680 of oats, 28,378 lbs. of wool, and 746,871 of tobacco. There were 12 grist mills, 9 saw mills, 1 tannery, 20 churches, and 485 pupils attending public schools. Capital, Owenton. II. A S. W. co. of Ind., drained by the West fork of White river and several smaller streams; area, about 400 sq. m.; pop. in 1860, 14,808. Its soil is fertile, especially near the borders of the streams. It contains extensive and very rich mines of coal and iron ore. The productions in 1850 were 764,029 bushels of Indian corn, 60,827 of wheat, 58,789 of oats, 2,176 tons of hay, and 89,581 lbs. of wool. There were 29 grist mills, 9 saw mills, 20 churches, and 1,158 pupils attending public schools. Capital, Spencer.

OWEN, JOHN, a British writer of Latin epigrams, born in Armon, Caernarvonshire, about 1560, died in 1622. He is called in Latin *Ovenus*, or *Audoenus*. He received a fellowship at New college, Oxford, in 1584, and took the degree of LL.B. in 1590. In the following year he resigned his fellowship, and taught school. Among continental scholars of his time he was called the "British Martial," such was the happiness, point, and linguistic purity of the Latin epigrams by which he became distinguished. He was a Protestant, and sometimes employed his wit against the Roman Catholic church, which caused his disinheri- tance at the hands of a rich uncle, and gave the collection of his epigrams in 1654 a place in

the *Index Expurgatorius*. The best edition of them is that by Renouard (Paris, 1794). Translations into English were made by Vicars, Packe, and Harvey, that by the last named author being the most complete.

OWEN, JOHN, an English preacher and scholar, born in Stadham, Oxfordshire, in 1616, died in London, Aug. 24, 1688. He was descended from a prominent family in North Wales. His precocious genius and his thirst for knowledge were so marked, that at the age of 12 he was entered at Queen's college, Oxford, receiving his bachelor's degree at 16, and his master's degree at 19. In the university he became noted not only for his diligence in study and mastery of the ancient tongues, but also for skill and vigor in athletic sports. The lead which he took in resisting Archbishop Laud's new academical regulations brought upon him the ill will of the high church party, and alienated the uncle to whose generosity his advancement thus far had been in some measure due. He was compelled to leave his place at Oxford, to accept orders in the church, and to support himself by private teaching and by officiating as chaplain, first to Sir Robert Dormer of Ascot, and afterward to Lord Lovelace. In this period Owen's mind was greatly exercised by doubts concerning his religious state and his duty in the crisis in national affairs, which resulted finally in his open adhesion to the side of the parliament against the king, and his adoption of nonconformist principles. The type of faith which he chose was strict Calvinism, and his first work, the "Display of Arminianism" (1642), was hailed as the sign of reaction against that wide-spread heresy. In reward for this service to the orthodox cause, he received the living of Fordham in Essex, where he remained a year and a half, and gained great fame as a pulpit orator. This fame was increased when he removed to the larger neighboring town of Coggeshall; and the change which he here made from the Presbyterian to the Independent form of church government only made him more popular with the masses, and with the party rising in power. In April, 1646, he was first called to preach before the parliament, and his ability was so conspicuous that he was frequently summoned to preach to that assembly, and had the dangerous honor of addressing them on the day after the execution of Charles I. Cromwell favored him, took him as private chaplain on his expeditions to Ireland and Scotland, and when he had received the office of dean in Christchurch college, made him in addition the vice-chancellor of the university. Though his administration came in a time of bitter theological contest, he gained the good will of all by his conciliating manners, and was able to subdue hatreds, to prevent outbreaks, and to accomplish important reforms. The 5 years in which he held this office were years of great literary and pastoral activity; he preached constantly, and published several of his most important

works, receiving moreover in 1658 the degree of D.D. The favor which he had enjoyed with Oliver Cromwell did not continue with the protector's son and successor. Presbyterian opposition deprived him of his vice-chancellorship, and at the restoration he was ejected from his deanery, and constrained to retire to his native town, where he purchased a small estate, and lived for a time in quiet. His passion for preaching nevertheless continued; and in spite of risks and prohibitions, and even attacks upon his house by the royalist soldiers, he persevered in addressing assemblies of his friends, and in expounding the principles of that Savoy confession which he had assisted in preparing. In a visit to London he became acquainted with Lord Clarendon, from whom he received tempting offers. In the period of toleration from 1667 to 1670, he took charge of an important congregation in Leadenhall street, London, to which his reputation and eloquence largely added, securing the favor of many of the nobility, and even for a time of the king and his Catholic brother. He had repeated interviews with Charles II. Though Owen's constitution was naturally robust, he had so strained it by excessive labor that it failed prematurely, and the last 12 years of his life were years of weakness and pain. His work on the "Glory of Christ" was hardly prepared for the press when its author finally yielded to his disease. He was buried at Bunhill fields, where his grave is still conspicuously marked. In personal appearance, Owen was tall, handsome, dignified, and courteous, and his royalist enemies all confessed the fascination of his manners. His strictness of opinion did not hinder him from being just and kind to opponents. He kept open house, aided poor students, and distributed favors to the Presbyterians, even when he denounced their principles. His learning was vast and accurate, not only in Christian divinity, but in rabbinical lore and in the classics. The reputation of his oratory is, it must be said, hardly justified by the style of his published writings, which, with all their wealth of thought and scholarship, are often dry, verbose, and tedious. Much of it, no doubt, was owing to his gifts of voice and manner. But even in the matter of style his writings will compare favorably with those of other Puritan divines. He had a reputation in other countries than his own, was at one time invited to a professorship in Holland, and was only prevented from emigrating to New England by an express order of the council. The familiar title applied to him by his Puritan brethren was the "prince of divines." Owen's works are very voluminous and on a great number of subjects. There were 7 volumes in folio, 20 in quarto, and 80 in octavo. The last edition was published in Edinburgh in 24 vols. 8vo. (1859).

OWEN, RICHARD, a British comparative anatomist and palaeontologist, born in Lancaster in 1804. At a very early age he entered the naval service as a midshipman on board the frigate

Tribune; but upon the conclusion of the general peace in 1815 he returned to his studies, and was for some years a pupil of Mr. Baxendale, a surgeon in Lancaster. In 1824 he attended medical lectures at the university of Edinburgh, and during a year's residence in that city acquired under the instructions of Dr. Barclay a predilection for the study of comparative anatomy. Repairing in 1825 to London, he became a student at St. Bartholomew's hospital, where his talents attracted the notice of Abernethy, then surgeon to the hospital, who employed him in the dissecting room as prosector. In 1826 he became a member of the royal college of surgeons, and from want of adequate professional employment procured the appointment of assistant surgeon in the navy. He was deterred from entering upon this career by the advice of Abernethy, who with characteristic roughness told him, if he went to sea, he would "go to the devil at once." Owen took the hint and remained on shore, and shortly after by the assistance of Abernethy was appointed assistant curator of the Hunterian museum, then deposited in the college of surgeons. This invaluable collection, the chief labor of Hunter's life, had so long been suffered to remain in obscurity, that at the time of Owen's appointment its existence was scarcely known to the public. Its preservation from injury or the effects of time or neglect was due to the efforts of Mr. Clift, for many years the assistant of the founder, and who had twice superintended its removal without the slightest damage to the frail and delicate preparations of which it in great part consisted. No attempt however had been made to render the museum of practical use to science by preparing a catalogue of its contents; and the destruction of Hunter's manuscripts and memoranda by his brother-in-law, Sir Everard Home, seemed to render the task hopeless. Nevertheless Owen applied himself to it with unremitting industry, and in conjunction with Mr. Clift produced the catalogue of the pathological specimens in the museum (2 vols. 4to., 1830), and that of the monsters and malformations (4to., 1831), both comprising descriptions of the specimens, but not histories of the cases. Thenceforth Mr. Clift devoted himself chiefly to the care of the museum, leaving Owen to pursue his labors in cataloguing the rest of its contents alone. Between 1833 and 1840 the latter produced the elaborate "Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy" (5 vols. 4to.), the amount of labor involved in which is well illustrated in his own statement contained in the 5th volume. "It is impossible," he says, "to reason correctly upon the structure of a detached organ, unless the condition of the rest of the organization, and the habits and mode of life of the species, be known; but to this end the name of the species from which the detached organ was derived is indispensable; without this fact the contemplation of the most

elaborately dissected specimen can yield little satisfactory information, and to determine it became, therefore, the first and most essential step in the formation of the catalogue of the physiological specimens. This part of their history has, in most cases, been effected by a comparison of the Hunterian preparations with recent dissections." This brief statement, as has been well observed, "gives the key to the fund of monographs and other papers which Prof. Owen has been able to contribute to the transactions of the societies devoted to specific branches of natural history;" for, while dissecting the specimens necessary to identify those of Hunter, he was constantly opening new paths of inquiry and making discoveries, the results of which bear testimony to "an activity seldom equalled, perhaps never surpassed." The dissection of so many animals also enabled him to add many preparations supplying links in the Hunterian series; and the account of these contributions, as well as of those from other sources, must be added to the descriptions of the 3,790 Hunterian specimens in order to form an idea of the labor which mainly occupied the first 10 years of his scientific career. The materials and suggestions thus acquired, to the number of which each succeeding year largely added, have been employed chiefly to illustrate 4 great departments of natural science, viz.: comparative anatomy and physiology, zoology, palaeontology, and transcendental anatomy and physiology. A brief recapitulation of his labors in each of these departments is all that can be attempted in this article. As an anatomist he has extended his labors over the 4 divisions of the animal kingdom, giving more attention to the vertebrates, and particularly to its chief division, the mammalia, than to either of the others. Among his papers on the mammalia, those devoted to the quadrupeds, the carnivora, and the marsupialia are the fullest and most important. To the "Proceedings of the Zoological Society" he contributed papers "On the Anatomy of the Orang Outang," "On the Cranium of the Orang Outang," "On the Comparative Osteology of the Orang and Chimpanzee," &c.; and to the "Transactions" a series entitled "Osteological Contributions to the Natural History of the Chimpanzee," in which the skeleton of the gorilla of western Africa was first fully described. His researches among the carnivora have extended to the Thibet bear, the lion, the tiger, the seal, and many other animals, whose anatomy he has studied with especial reference to extinct forms of the same family. In this manner the sloths and armadillos have supplied him with hints as to the structure of the megatherium, the mylodon, and similar creatures of an earlier epoch. The marsupialia have formed a distinct and important study with him, and their position among the mammalia has been determined by observations extending through many years, the results of which are to be found in papers scattered through the "Philosophical Transactions," the

"Transactions of the Zoological Society," and the "Reports" of the British association. He also published "Outlines of the Classification of Marsupialia." An account of his proposition for a fourfold division of the mammalia, based upon the 4 leading modifications of the cerebral system, will be found in the article MAMMALIA. His researches among the birds, reptiles, and fishes, both with respect to their classification and their connection with extinct species, have been not less remarkable; and in connection with this branch of his labors he has opened a rich field of inquiry among the extinct birds of New Zealand, resulting in the discovery of the gigantic genus *dinornis*, with many of its species, and several kindred genera. The "Transactions" above cited, and the "Cyclopædia of Anatomy and Physiology," contain abundant evidences of the attention he has given to the invertebrate animals, the mollusks and articulate animals having been examined with particular care. His "Mémorial on the Pearly Nautilus," published in 1832, containing a description of its anatomy, and a proposal for a new classification of the family of cephalopodous mollusks, was followed by an important series of papers on the same subject. In the investigations above alluded to he made frequent use of the microscope, and was one of the founders and the first president of the microscopical society; and it is to his intelligent employment of this instrument that we are indebted for a series of observations on the structure of the teeth of animals, in accordance with which he in 1849 divided the mammalia into two classes, the monophyodonts, or those generating a single set of teeth, and the diphyodonts, which generate two sets. The most important results of these researches were embodied in his "Odontography" (3 vols. 8vo., London, 1840-'45), a work embracing within its scope the dental economy of the whole animal kingdom, and illustrated with numerous drawings of the microscopic appearance of the teeth of animals. It is, however, as a palaeontologist that Mr. Owen is perhaps best known to the scientific world, and his researches in the little explored field of extinct animal life would alone suffice to stamp him as a profound naturalist. Employing his knowledge of the anatomy of living animals to determine the remains of those which no longer exist, he has constructed numerous extinct families of vertebrata, the existence of which had not previously been even surmised; and in instances where his provisions were founded on a footprint or the fragment of a bone, subsequent researches and discoveries have amply confirmed his opinions. His anatomical knowledge seems to delight to grapple with difficult subjects, and the science of palaeontology exhibits no more remarkable results than his descriptions of the complicated structure of the cheirotherium or of various species of the great family of *dinornida*. His publications in this department of natural history comprise a "History of British Fossil

Mammals and Birds" (8vo., London, 1846), containing the description of nearly 150 species, a large number of which were discovered by himself; a "Description of the Skeleton of an extinct gigantic Sloth (*Myodon Robustus*), with Observations on the Osteology, Natural Affinities, and Probable Habits of the Megatheroid Animals in General" (4to., 1842); a "History of the British Fossil Reptiles" (4to., 1848-'55); beside reports on the saurian reptiles and numerous papers on the *reptilia* found in different geological formations of Great Britain, on the *dinornids*, and on various families of mammalia, published in the "Transactions" of the zoological society and in the "Proceedings" of the British association for the advancement of science and of the palaeontographical society. Among the numerous skeletons he has put together are those of the mylodon and glyptodon, both of which were first described by him. In the department of transcendental anatomy Mr. Owen was the first to develop the idea of Oken, which had been looked upon with indifference or distrust by Cuvier and other naturalists, that the typical form of the skeleton in the higher animals is the vertebra. His works "On the Archetype and Homologies of the Vertebrate Skeleton, with Tables of the Synonyms of the Vertebral Elements and Bones of the Head of Fishes, Reptiles, Birds, Mammals, and Man" (1848), and "On the Nature of Limbs" (8vo., 1849), are considered to have demonstrated the existence of a general plan in the structure of the skeleton of the vertebrata. On other subjects embraced within the labors of the philosophical or transcendental school of anatomists he is considered a first-rate authority, his views being "that there is in the history of creation a progress from the general to the special; that the lower and more incomplete forms of animals were first created; and that the higher forms have been the last to appear on the surface of the earth." In 1836 Mr. Owen was appointed Hunterian professor at the royal college of surgeons, in the place of Sir Charles Bell, in which capacity he delivered several courses of lectures, embracing the whole animal kingdom, and containing a *résumé* of his previous labors on the structure and classification of animals. These were published under the title of "Lectures on Comparative Anatomy" (2d edition, 1853). In 1856 he was appointed chief of the natural history department of the British museum, which position he still holds, giving in connection with it annual courses of lectures on natural history. Not the least useful of his labors have been those connected with the subject of the sanitary condition of large towns, which his efforts have tended greatly to improve. He was one of the commissioners of inquiry into Smithfield market, and successfully urged its removal. He has received the royal and Copley medals, and various honors from seats of learning, and is a member of the chief scientific bodies of

the world. He is also in the receipt of a pension, and has a residence in one of the royal houses in Bushy park. A list of his publications may be found in the *Bibliographia Zoologica et Geologica* of the Ray society, and extended notices of his labors are contained in the "Quarterly Review" for 1852-'3, in which it is justly said: "From the sponge to the man no form of animal life has escaped his researches, and he has thrown light on each subject."

OWEN. I. ROBERT, an English social reformer, born in Newtown, Montgomeryshire, in 1771, died there, Nov. 19, 1858. Although the son of poor parents, he received a respectable education. He entered upon commercial life, and when 14 years old procured a situation in London, where he so recommended himself by his talents for business, that at the age of 18 he became partner in a cotton mill, and subsequently removed to the Chorlton mills near Manchester. Prospering in this undertaking, he married in 1801 the daughter of David Dale, a Glasgow manufacturer, and afterward assumed the charge of a large cotton factory in New Lanark, Scotland, belonging to his father-in-law. Here he introduced a system of reform (see LANARK) which proved for a time highly successful. He then turned his attention to more extensive social evils, and published in 1812 "New Views of Society, or Essays upon the Formation of Human Character;" and subsequently a "Book of the New Moral World," in which he maintained a theory of modified communism, insisting on an absolute equality in all rights and duties, and the abolition of all superiority, even that of capital and intelligence. By the aid of his immense fortune he was enabled to distribute a large number of tracts developing his peculiar views, and soon had everywhere numerous and enthusiastic followers. But, attacked on all sides, and particularly by the religious press, he set out in 1823, after the death of his patron, the duke of Kent, for the United States, where he determined to found at his own cost a communist society; and with this view he bought from Rapp the settlement of New Harmony in Indiana, on the banks of the Wabash, embracing 30,000 acres of land and dwellings for 2,000 persons. The scheme, however, proved an utter failure, and in 1827 he returned to England, where experiments of a similar nature attended by a similar result were made at Orbiston in Lanarkshire, and at Tytherley in Hampshire. He succeeded no better in establishing a "labor exchange" in London, in connection with a bazaar and bank. In 1828 he went to Mexico on the invitation of the government to carry out his experiment there, but effected nothing. His ill success, however, neither weakened his confidence nor lessened his activity, and during the remainder of his life he constantly appeared before the public as a lecturer and journalist. His ideas are most clearly developed in his "Lectures on a New State of Society," "Essays on the Formation

of Human Character," and "Outline of the Rational System," and especially in his principal work, "The Book of the New Moral World," in which he came forward as the founder of a system of religion and society according to reason. He and his followers, the so called Owenites, became in 1827 the soul of the labor leagues, out of which sprang the chartist movement. During his last years he was a believer in spiritualism, and published several conversations held with Benjamin Franklin and other persons. He was one of the first, if not the first to found infant schools, and through him they were introduced into England. II. ROBERT DALE, an American author and politician, eldest son of the preceding, born in New Lanark in 1804. He accompanied his father to America, and there remained. Embracing the political views of the democratic party, he was a representative in congress from Indiana from 1843 to 1847, and was sent in 1853 to Naples by President Pierce as chargé d'affaires, which station he held until 1858. He took a prominent part in the organization of the Smithsonian institution, of which he was one of the first regents. He has written several works, among which may be mentioned "New Views of Society" (12mo., New York, 1825); and "Hints on Public Architecture," with 118 illustrations, published by the Smithsonian institution (4to., New York, 1849). His last work, entitled "Footfalls on the Boundaries of Another World" (Philadelphia, 1859), is a collection of stories of supernatural events, claimed to be well authenticated. III. DAVID DALE, an American geologist, brother of the preceding, born in Lanarkshire, Scotland, June 24, 1807, died in New Harmony, Ind., Nov. 18, 1860. He was educated with his brother Robert Dale at Hofwyl, Switzerland, and in 1826, accompanied his father to the settlement established by the latter in New Harmony. He subsequently passed two years in studying geology and other branches of natural science in Europe, and in 1833 took up his permanent residence in the United States. In 1835 he received the degree of M.D. from the Ohio medical college, and two years later was employed by the legislature of Indiana to make a geological reconnaissance of the state, the results of which were published in a small work of which a reprint appeared in 1859. He subsequently, under instructions from the general land office, made a minute examination of the mineral lands of Iowa; and in 1848, having spent the interval chiefly in scientific studies, he was employed by the government to conduct the geological survey of Wisconsin, Iowa, and Minnesota. The result of 8 years' labor in this extensive field was in 1852 published by congress in a 4to. volume, embracing over 600 pages, accompanied by numerous maps and illustrations executed in the highest style of the art. During the next 5 years, from 1852 to 1857, he conducted the survey of the state of Kentucky, 3 volumes relating to which

with maps and illustrations have been published; the 4th was sent to press a few weeks before his death. In 1857 he was appointed state geologist of Arkansas, and in the succeeding year the report of his survey was published in 1 vol. 8vo. The preparation of a companion volume to this was among his latest labors. He also conducted various important examinations for private individuals and corporations. He was an indefatigable and enthusiastic laborer in his peculiar walk, and hastened his death by the exposure incidental to camp life in the miasmatic regions last surveyed by him. He had just finished a private museum and laboratory, said to be one of the most complete in the country.

OWEN, WILLIAM, an English painter, born in Ludlow, Shropshire, in 1769, died in London, Feb. 11, 1825. He was instructed in painting by Cotton and Sir Joshua Reynolds, and in 1792 commenced his career as a portrait painter. His portrait of Sir William Scott, afterward Lord Stowell, has been pronounced worthy of Vandyke. In 1806 he became a royal academician. He declined the honor of knighthood as an expensive distinction. He painted some fancy pieces, including the "Daughter of the Beggar of Bethnal Green," the "Sleeping Girl," the "Children in the Wood," &c. According to Wornum, he was superior to Lawrence in male heads.

OWHYHEE. See SANDWICH ISLANDS.

OWL, the general name of the nocturnal birds of prey constituting the family of *strigida*, of which there are 5 sub-families, 18 genera, and about 150 species, more than 40 of which inhabit America. Owls may be at once recognized by their short and bulky form, with head disproportionately large, fully feathered, and often furnished with erectile tufts like the ears of quadrupeds; the eyes are very large, directed forward, more or less surrounded by a disk of radiating bristly feathers, and in most formed for seeing in twilight or at night, presenting a ludicrous vacant stare when exposed to daylight; lores densely covered with bristly feathers directed forward, nearly concealing the short, strong, and hooked bill; ears large, with a kind of operculum or cover, enabling them to hear slight noises in the stillness of night; the wings are generally moderate, broad, and rounded, the outer edge of the primaries with separated barbs, adapted for vigorous and noiseless but not rapid flight in pursuit of living prey in morning and evening twilight; the tail broad, and of various lengths; tarsi usually short, strong, feathered to the toes except in the Asiatic genus *ketupa*; the inner toe the longest, and the outer capable of being turned back as in scansorial birds; the claws long, curved, and very acute. The plumage is soft and downy; the female is the larger, resembling the male in colors; the expression of the face and eyes is cat-like; the eggs are 2 to 5, and white, and the young are covered with a fine down. The mouth is very wide, and the

oesophagus capacious, leading directly to the stomach, without any dilatation or crop; the intestines are short, and with 2 large caeca. Owls are solitary birds, retiring during the day to holes in trees, caves, or old buildings, where they roost and breed; most are nocturnal, but a few fly by day, in habits resembling the *falconida*, especially the kites; the larger species feed on small quadrupeds (particularly mice) and birds, and the smaller on insects, such as moths and large beetles; if the prey be small, it is swallowed whole, or is torn to pieces if necessary, and the indigestible portions, such as feathers, hair, and bones, are disgorged from the stomach in small pellets. They are great benefactors to man by destroying mice and other noxious animals; but from their nocturnal habits and dismal screeching cry they are generally regarded with superstitious fear, and as ominous of some present or future calamity or foul deed. In the Scriptures the owl is almost always associated with desolation; painters, poets, and story tellers introduce it as a bird of ill omen, and as the companion of ghosts, witches, demons, and magicians; almost all uncultivated nations look upon it as an unwelcome visitor; the ancient Greeks and Romans, however, made it the emblem of wisdom, and sacred to Minerva, and indeed its large head and solemn eyes give it an air of wisdom, which its brain does not sanction.—In the 1st sub-family, the *strigina*, the size is never very large; the head is smooth and bulky, and the facial disk perfect; the bill rather long, eyes rather small, legs long and feathered to the toes. In the genus *strix* (Linn.) belong the barn owls; in this the wings are long, and the head without tufts; of the dozen species scattered over the world will be mentioned only two. The American barn owl (*S. pratineola*, Bonap.) is 18 inches long, with an extent of wings of 8½ feet in the female; the male is an inch shorter and 2 inches less in extent. The general color above is yellowish or grayish brown, finely mottled with light yellowish red, each feather having toward the end a central deep brown streak ending in a grayish white spot; quills and tail transversely banded with blackish brown; under coverts of wings and tail white; under parts pale brownish red, fading anteriorly into white, each feather tipped with a dark brown spot; the face white, tinged with red, with a ruff of light brownish red; the bill, toes, and claws light yellowish. It occurs throughout temperate North America, breeding at all seasons in the southern states; it is not found far from the sea, and frequents the borders of woods and open abandoned fields; it feeds almost entirely on quadrupeds, and sometimes digs up moles and mice like the burrowing owl; its flight is light, regular, and protracted, and it runs rapidly; according to Audubon it makes no cry, but utters a hollow hissing sound. The European barn owl (*S. flammea*, Linn.) is considerably smaller than the American, being only

14 inches in length and 8 feet in extent of wings; it is lighter colored, more yellowish, with gray and brown zigzag lines and whitish dots above; it is whitish below, and the ruff is white. It is found abundantly in Great Britain and other temperate parts of Europe, in Asia, and in Africa, especially in cultivated districts in the neighborhood of fields and farm yards where it can find a plentiful supply of mice; though a single bird will destroy annually several hundred mice and moles, beside noxious insects, it is constantly persecuted for its alleged injury to game birds and the dove cote; it sometimes captures fish by dropping upon them in the water; its general note is a screech, hence it is commonly called screech owl in Great Britain; it rears several broods in a season between July and December. In the genus *phodilus* (Is. Geoffr.), the single species *P. badius* (Hornst.), found in the thick forests of Java, in the haunts of the tiger, is said to be very familiar with this animal, even alighting on its back; the native name is *wowo-wui*.—In the 2d sub-family, the *bubonina*, the facial disk is incomplete above the eyes and bill, and the large, broad, and flat head is furnished with a pair of long erectile ear tufts, which have given them the name of horned owls; legs and claws usually very strong. This family is spread all over the world, except in Australia, and contains some of the largest as well as some of the smallest of the family. The genus *bubo* (Ouv.) is of large size and robust form; the large eyes and ear tufts have given them the name of cat owls; the wings are long, the tail short, the legs densely feathered, the bill short, and the claws very strong. The American great horned owl (*B. Virginianus*, Gmel.) is from 20 to 25 inches long, with an extent of wings of 4½ to 5 feet, the bill along the ridge 2 inches, and the ear tufts 8; the color is variable from dark brown to nearly white; the general color above is dark brown, every feather mottled with irregular lines of pale ash and reddish fulvous, the base of each being of the latter color; throat and neck white, breast with longitudinal black stripes, rest of under parts mixed white and fulvous with narrow transverse dark brown lines; iris yellow, bill and claws bluish black. It is found throughout North America, and probably also in South America, several varieties being described in different latitudes, in mountain and plain, on the seashore and in the interior; the flight is elevated, rapid, and graceful; it makes a great variety of sounds, barking like a dog, hallooing and leading astray the benighted traveller, saluting him by notes like the half suppressed screams and gurglings of a suffocating person, or deceiving him by a low "hoo-hoo-hoo-e" which seems a great distance off. It commits great havoc in the farm yard, seizing all kinds of domestic poultry, to which may be added grouse, ducks, hares, squirrels, and opossums, and even dead fish. They begin to pair in February, making a bulky nest usually on a large horizontal branch, and rear only one

brood of 3 to 6 in a season. It is a bold and powerful bird, bravely resisting when attacked. The European horned or eagle owl (*B. maximus*, Sibb.), *le grand duc* of the French, is about 26 inches long with an extent of wings of 5 feet; it is common in the forests of Europe from the Mediterranean to Norway and Lapland, but is rare in Great Britain; it occurs also in Asia; its habits are the same as those of the American bird; the general color is ferruginous, varied with spots and markings of brown, black, and gray; in captivity it is fierce, hissing, snapping, and barking when irritated, but making no other noises. The *B. Bengalensis* (Frankl.) feeds principally upon rats, and compensates for some of the mischief done by the other species. The genus *scops* (Sav.), or *ephiates* (Keys. and Blas.), is characterized by small size, conspicuous ear tufts and large head, and long tarsi more or less covered with short feathers. The mottled or American screech owl (*S. asio*, Linn.) is about 10 inches long and 22 in extent of wings; in the adults the plumage above is pale ashy brown with longitudinal brownish black lines, mottled with the same and cinereous, and below ashy white with similar stripes and lines; bill and claws horn color; in young birds the upper parts are pale brownish red, in some parts rufous, and below yellowish gray, hence called the red owl. This is the most abundant owl in the Atlantic states, and is found over the whole of temperate North America, and even as far as Greenland; its food consists principally of beetles and field mice, which it seeks in the neighborhood of farm houses, orchards, and gardens, where it is rarely molested; its notes are mournful and tremulous, like the chattering of teeth, but loud enough to be heard for several hundred yards. The little horned owl of Europe (*S. Adrovandi*, Ray) is about 8 inches long, of a light gray color variegated with brown, with longitudinal brownish black lines and transverse undulations; it is most abundant in southern Europe in wooded districts, where it feeds on insects and mice; it is also found in N. Africa and Asia, and rarely in Great Britain; it nestles in cavities in rocks and holes in trees, laying 2 to 4 eggs; it is gentle, and readily tamed; its notes are plaintive and monotonous, resembling "ken, ken," and are kept up regularly the night long. In the genus *otus* (Ouv.) the form is larger and more slender, the head moderate with more perfect facial disk, and the eyes rather small. The American long-eared owl (*O. Wilsonianus*, Less.) is about 15 inches long, with an extent of wings of 3½ feet; it is rather a handsome bird, very intricately marked, and may be generally described as of a buff color, mottled and spotted with brown and grayish white; it inhabits the whole of temperate North America, and even the shores of Hudson's bay; it is strictly nocturnal, preying upon insects, and small mammals and birds; it deposits its eggs in the abandoned nest of other birds, in a fissure of

a rock, a hole in a tree, or a hollow in the ground; its cry is plaintive, consisting of 2 or 3 prolonged notes repeated at intervals. The European long-eared owl (*O. vulgaris*, Flem.) bears a strong resemblance to the American species, and is one of the most abundant of the family in England, where it remains all the year round; it is intricately dappled with dark brown and black upon pale brown, and is a very handsome bird; it frequents old ivy-covered towers and trees, where it remains during the day; it rarely makes a nest of its own, using those of the crow or squirrel. The American short-eared owl has been made, with others, into the genus *brachyotus* (Gould), characterized by inconspicuous ear tufts; this species (*B. Cassinii*, Brewer) is about 15 inches long, with an extent of wings of 3½ feet; the plumage is reddish buff, streaked longitudinally with dark brown, the tail being of the latter color barred and tipped with reddish buff; it is found in North America from Greenland to Cuba and from the Atlantic to the Pacific, in the eastern states in the winter preferring the vicinity of marshes and meadows; it is very fond of remaining on the ground, on which it advances by long leaps. The European short-eared owl (*B. palustris*, Gould), 16 inches long, and 40 in alar extent, much resembles the preceding species; it seeks its food by day, even in full sunlight, pursuing pigeons and domestic fowls into the farm yard, though feeding chiefly upon mice. In the Asiatic genus *ketupa* (Lesson) the long tarsi are covered with scales instead of feathers; the *K. flavipes* (Hodgs.) is somewhat diurnal, and plunges into streams in pursuit of fish and crabs; the *K. Ceylonensis* (Gmel.) is said to have a very disagreeable hoarse and hollow laugh, like the syllables "haw, haw, haw, ho."—In the 8d sub-family, the *synnina* or gray owls, the head is large, with very small and concealed or no ear tufts; the facial disk nearly perfect, eyes small, wings rather short, and tarsi and toes generally fully feathered. Though this sub-family contains some of the largest owls, the size is usually moderate and sometimes even small. In the genus *synnium* (Sav.), characterized by large size, and long, wide, and rounded tail, belongs the great gray owl (*S. cinereum*, Gmel.), the largest in North America, and one of the largest of the family, about 30 inches long, with an alar extent of 4 feet; the prevailing color is ashy brown above mottled and barred with ashy white, the under parts of the latter color, with longitudinal brown stripes on the breast, and transverse ones of the same on the abdomen; quills and tail brown, with 5 wide bands of ashy white; bill yellow. It is found in North America from New Jersey to Hudson's bay; it is rather diurnal in habit, frequenting wooded districts, and preying on hares and other rodents; its cry resembles that of the mottled owl. The barred owl (*S. nebulosum*, Forst.) is about 20 inches long, and 40 in alar extent; the bill is yellow; the general color above is light reddish

brown, largely spotted with white on the back and wing coverts; wings and tail tipped with grayish white; below pale brownish red, marked on the neck and upper breast with transverse and below this with longitudinal brown streaks; abdomen yellowish white; plumage, as in the preceding species, remarkably soft and downy. It is found in North America east of the Mississippi, especially in the southern states, in retired woods, even in the daytime; its loud discordant cry of "whah, whah, whah-aa," frequently repeated at evening twilight, has a ludicrous sound, compared by Audubon to the affected laugh of some fashionable people; its odd and lively movements entitle it to the name of the "buffoon of the woods." It preys on half-grown chickens, young hares and rabbits, squirrels, mice, small birds, and frogs; it begins to lay in the middle of March in a hollow tree, and raises a single brood in a season; in captivity it makes an excellent mouser; as it often appears in the daytime, it is especially liable to the attacks of diurnal birds, which have a natural antipathy to the whole family; its flesh is sometimes exposed for sale in the markets of New Orleans, and is considered palatable by the negroes. The hooting or tawny owl of Europe (*S. aluco*, Linn.) is about 15 inches long and 34 in alar extent; the upper parts are brownish red, tinged with gray, with longitudinal dark brown streaks and transverse lighter lines, and lower parts reddish or yellowish white with similar markings; large white spots on wing coverts; its cry is very doleful, like "hoo, hoo, hoo," or the howling of a wolf; it is strictly nocturnal, inhabiting thick woods, preying on the usual animals and birds, and sometimes seizing fish in the water. In the genus *nyctale* (Brehm.) the size is small, with very small ear tufts, facial disk nearly perfect, wings long, tail short, and legs and toes densely feathered. Here belongs the little Acadian owl or saw-whet (*N. Acadica*, Gmel.), about 8 inches long and 18 in alar extent; the upper parts are olivaceous brown, the back of neck, rump, and scapulars spotted with white; face and under parts ashy white, the latter with pale brown streaks; quills and tail brown, spotted with white; bill and claws dark. This is the smallest owl found in the eastern and middle states, and probably occurs over the whole of temperate North America. This lively and handsome owl is called "saw-whet," as its love notes much resemble the noise made by filing the teeth of a saw, often leading the inexperienced traveller to expect to find a sheltering saw mill in the depths of the forest; it is sometimes also called screech owl in the middle states; it is not unfrequently caught in large cities, and is nocturnal in its habits; its usual cry resembles that of the little horned owl of Europe. Another species is Tengmalm's owl (*N. Richardsonii*, Bonap.), the largest of the genus, rarely seen in the United States, though common at Hudson's bay; it is about 11 inches long; its cry is a single melancholy note, re-

peated at intervals of a minute or two. Its European representative is the *N. funerea* Linn.), chocolate brown above, spotted with white, and yellowish white below, with brown streaks.—The 4th sub-family, *athenina* or bird owls, are of small size, with very imperfect facial disk, head without ear tufts, and tarsi thinly covered with feathers; rather diurnal in habit. The genus *athene* (Boie) has rather long wings, short bill and tail, long tarsi, and naked toes, and contains the burrowing owls. The American burrowing owls (*A. cunicularia*, Mol.; *A. hypugae*, Bonap.) occupy respectively the country west of the Rocky mountains and that portion between these and the Mississippi river; the former may be distinguished from the latter by its rather larger size and the feathering of the tarsus uninterrupted to the toes; the plumage is light ashy brown above, with numerous large white spots; breast light brown, white-spotted; abdomen yellowish white with brown spots; the length is from 9½ to 10½ inches. They are found in considerable numbers on the plains in the Rocky mountains, inhabiting the burrows of the prairie squirrels and other rodents, to which they flee when alarmed, and in which they live and bring up their young; they are strictly diurnal, and feed on grasshoppers, crickets, and field mice; in other parts of the world they dig their own burrows. There are several species in India, where they sometimes make loud and continual noises; the *A. scutellata* (Raffl.) is said to make a noise like that of a half strangled cat; there are more than 40 species, mostly confined to warm climates; they are said to be remarkably infested with fleas.—The 5th sub-family is the *nycteinina* or day owls, characterized by compact form, moderate head without tufts, rather long wings and tail, and strong and densely plumed tarsi; it embraces only 2 genera, each with a single species, inhabiting the arctic regions of both hemispheres, migrating southward in winter. In the genus *nyctea* (Steph.) the size is large, the head has no facial disk, and the legs and bill are rather short. The snowy owl (*N. nivea*, Daud.) is from 21 to 27 inches long, with an alar extent of 4½ to 5½ feet, and a weight of 4 to 5 lbs., according to sex; the general color is white, with the upper part of head and back with lunated dark brown spots, and the breast, sides, and thigh coverts with curved lines of the same; wings and their coverts and tail barred with oblong brown spots; some specimens, probably old birds, are almost entirely white. It is found in the northern regions of America, Europe, and Asia, coming within the United States as far as Georgia in the winter; it hunts in the daytime and at morning and evening twilight; of rapid and powerful flight, it strikes ducks, grouse, pigeons, &c., on the wing like a falcon, and seizes hares, squirrels, and rats from the ground, and fish from the shallows; from its color it is seen with difficulty amid the rocks and snow in its favorite haunts.

In the genus *urnia* (Dum.) the form is stout, but larger and more hawk-like; the wings and tail are long, and the legs rather short. The hawk or day owl (*S. ulula*, Linn.) is 16 to 17 inches long, with an alar extent of 88; the upper parts are sooty brown, with white spots on the shoulders; throat white, with dark brown stripes; brown spot on each side of breast; beneath with transverse lines of pale ashy brown; quills and tail brown, with numerous white bands; bill pale yellow. It is found in the northern regions of both hemispheres, in this country rarely going as far south as Pennsylvania; it is common in the fur countries, where it is often seen hunting by day, approaching the camps with great boldness; in the summer it feeds on squirrels, mice, and insects, and in winter principally on the ptarmigan and grouse. This bird approximates to the falcons in its bold and diurnal habits, and in the absence of facial disk and ear tufts, smaller size of the head, smaller eyes, and less developed ears; its eyes are adapted for the dim light of snow-clad and arctic regions.

OWL PARROT, a singular bird of the cockatoo family, of the genus *strigops* (Gray), found in New Zealand. In the only species described (*S. habroptilus*, Gray) the bill is high and short, grooved on the sides, with much curved culmen, acute tip, dentated lateral margins, and base covered by hair-like feathers; the wings are short and rounded, the 5th and 6th quills equal and longest; tail moderate, weak, much rounded, and each feather pointed with the shaft projecting; tarsi short and robust, covered with rounded scales; claws long, strong, and slightly curved. This is the *kakapo* or night parrot of the natives; it is about 2½ feet in length, of a dirty green color, with black transverse bands and brownish and yellowish spots; bill yellowish white. It has the general form of a parrot, with the facial expression, nocturnal habits, and noiseless flight of the owls; it lives in holes which it digs in the ground at the roots of trees; it is solitary, rarely seen, preferring moist and dark woods, and keeps chiefly on the ground, where its tracks are said to resemble those made by the human foot; its food consists of the roots of ferns and the outer covering of the New Zealand flax (*phormium tenax*); it breeds in February, laying 2 or 3 eggs; the voice is a hoarse croak. According to the natives, these birds assemble in the winter in caves in large numbers, dispersing again in the spring with a great noise; their flesh is white and is considered good eating. For an account of its habits see "Proceedings of the Zoological Society of London" (1852).

OWSLEY, an E. co. of Ky., intersected by the Kentucky river; area, about 460 sq. m.; pop. in 1850, 8,774, of whom 186 were slaves. It has a hilly and very broken surface, and a not very fertile soil. There are extensive forests and rich iron and coal mines. The productions in 1850 were 164,021 bushels of Indian corn, 8,843 of oats, 8,002 lbs. of wool, and

8,180 of tobacco. There were 2 newspaper offices, 6 churches, and 200 pupils attending public schools. Capital, Booneville.

OX. See OATTLE.

OX GALL, the bile of the ox, a viscid green or greenish yellow fluid, of bitter and slightly sweetish taste, and a peculiar nauseous odor, found chiefly in a membranous bag in the ox. It varies in consistency, sometimes being very limpid, and at others like a sirup. Potash and soda render it clearer. Its chemical composition is highly complicated, and is variously given by different authorities. The following is perhaps as nearly correct as any of the analytical results, viz.: in 800 parts—water 700, picromel 69, resinous matter 15, yellow matter 4, soda 4, phosphate of soda 2, chlorides of sodium and potassium 8.5, sulphate of soda 0.8, phosphate of lime and perhaps of magnesia 1.2. Ox gall possesses properties which render it of value in the arts, and it has also been supposed to have medicinal properties as a tonic and laxative, and has been prescribed particularly with the view of increasing the biliary secretion. It dissolves greasy matters; and for cleansing woollen stuffs upon a large scale it is sometimes preferred to soap. To preserve it from putrefying it need only be evaporated at a gentle heat to the consistency of an extract; and when wanted for use it may be dissolved in water slightly alkaline. The purified ox gall is much used for artists on account of its property of combining with colors, giving them more tenacity and fixing them strongly, while it also makes them flow more freely and often increases their lustre. It may either be mixed with the colors or applied to the paper after the colors. It is advantageously applied combined with gum Arabic as a light varnish, which however admits of other shades being added without mixing with the first. With lampblack and gum water it makes a beautiful black paint or ink that may be used instead of India ink. The lampblack is first mixed with the gum water, and the purified ox gall is then added. It fixes sketches in lead pencil, and does not prevent these from being afterward tinted with colors in which a small proportion of ox gall is mixed. It is highly recommended for use in painting on ivory, as it removes from this all greasy matter, and causes the colors to spread freely, and penetrate into the ivory. It is equally useful in the application of paints to transparent paper. For these effects it is essential that the purified article should be prepared from very fresh ox gall. The method of purifying in best repute is as follows: To a pint of the gall boiled and skimmed add an ounce of pulverized alum, and leave the liquor on the fire till the combination is complete. Another pint is treated in the same way with an ounce of common salt instead of alum. When cold the liquids are separately bottled and loosely corked. They should then be kept for 3 months, when a sediment subsides, and the liquor becomes clearer. There is still present

a yellow coloring matter which would affect green and some other colors, and which is separated as a coagulum by turning off and mixing the clear portions of the two mixtures in equal quantities. The liquid is then obtained by filtering perfectly purified and colorless. It improves by age, and never disengages a bad odor, nor loses its useful properties.

OXALIC ACID, an important and powerful acid discovered by Scheele in 1776, or as claimed by some by Bergman; symbol $\text{HOC}, \text{O}, 2\text{HO}$; chemical equivalent 68. It occurs in vegetables, animals, and rarely in minerals, as in the form of sesquioxalate of iron in Humboldtite. Of the juices of plants it is a frequent constituent. Its name is derived from its giving to the leaves of the wood sorrel (*oxalis acetosella*) their very acid taste. In this and in the common sorrel (*rums acetosa*), it occurs combined with potash as binoxalate of potash. Combined with lime, it gives solidity to many lichens, and is found in the roots of rhubarb, valerian, and other plants. It is found in a free state in the bristles of the chick pea (*cicer ariselinum*). It is artificially produced by the oxidation of sugar or of starch by nitric acid; other organic substances may be substituted for those named, as rice, gum, wool, hair, silk, &c. Schlesinger's method, recommended by Berzelius as producing it in the largest quantity and of the purest quality, is to dissolve 1 part of dry loaf sugar in $8\frac{1}{2}$ parts of nitric acid of specific gravity 1.38, and heat in a flask till effervescence, caused by the escape of carbonic acid and nitric oxide, ceases. The solution is then evaporated by a water bath to $\frac{1}{2}$ of its bulk, and the acid crystallizes on cooling. The product varies greatly in quantity according to the manner in which the nitric acid is applied. It is sometimes rated at little more than half the amount of sugar; but 100 lbs. of sugar should produce from 125 to 180 lbs. of oxalic acid, and the same weight of molasses from 105 to 110 lbs. The manufacturing chemists are said to use a mixture of 112 lbs. of sugar, 560 lbs. of nitrate of potash, and 280 lbs. of sulphuric acid, and to obtain 185 lbs. of oxalic acid and 490 lbs. of supersulphate of potassa. The crystals are colorless, transparent prisms of 4 or 6 sides. They have a very sour taste, and dissolve in 9 parts of cold or about 1 part of boiling water. In a very dry atmosphere they effloresce slightly, and gently heated they become opaque, and lose 2 atoms (28.5 per cent.) of water, their composition then being HOC, O . The crystals may crumble to powder, and even be almost wholly sublimed, without decomposition; but the other atom of water is expelled only at a decomposing heat, when the compound is converted into carbonic and formic acids and carbonic oxide. If the whole of the water be abstracted by treatment with strong sulphuric acid, the elements of dry oxalic acid are instantly resolved into equal volumes of carbonic acid and carbonic oxide. The compounds of oxalic acid may be anhydrous,

as oxalate of lead, or retain one equivalent of water, as oxalate of lime. Of the compounds formed by oxalic acid, those of special interest are the oxalates of potash and the oxalate of lime. The former, known as "essential salt of lemons," are employed to remove ink stains from linen; the excess of acid unites with the oxide of iron of the ink and converts this into a soluble oxalate, which is then removed by water. For lime oxalic acid has a very strong affinity, separating it from its solution in much stronger acids, and converting it into an insoluble oxalate. The acid is consequently an excellent test of the presence of lime in solutions, and is used for this purpose, chiefly in combination with ammonia. Conversely, lime water is a test of the presence of oxalic acid, which is determined by the formation of a precipitate insoluble in excess of acid.—Oxalic acid is a corrosive poison, extremely virulent and rapid in its effects when taken into the stomach in large doses; and from the resemblance of its crystals to those of Epsom salts, it has often been sold and administered instead of this purgative with fatal effects. Its intensely sour taste might at once detect it; but the dose is usually swallowed in haste without suspicion of danger. The acid corrodes the mucous membrane of the throat and stomach, causes intense pain and violent attempts to vomit, and death sometimes ensues in 10 minutes. Emetics and the stomach pump may be immediately applied, but the true antidote is copious draughts of water containing pulverized chalk or magnesia. These neutralize the acid, forming with it an insoluble oxalate of lime or magnesia, either of which is harmless. Though so dangerous in large doses, oxalic acid largely diluted with water and sweetened with sugar may be used as a refreshing beverage in febrile diseases; and it has even been recommended as a remedy for inflammation of the mucous membrane.—Oxalic acid is largely employed in calico printing for discharging colors; it is also used for cleaning the straw of bonnet makers, the leather of boot tops, and for removing stains of ink and iron rust from fabrics.

OXENFORD, JOHN, an English miscellaneous author, born at Camberwell, near London, in 1812. He was admitted to the bar in 1833, but turned his attention principally to literature and the drama, and has produced several pieces for the stage, among which the most popular are: "My Fellow Clerk" (1835), "Twice Killed" (1835), and "A Day Well Spent" (1836). He has also been a student of French and German literature, and has published translations of part of the "Autobiography of Goethe," the "Conversations of Eckermann with Goethe" (1850), the "Hellas" of Jacobs (1855), a collection of songs from the French, entitled "Illustrated Book of French Songs" (1855), and Kuno Fischer's "Essay on Lord Bacon and his Philosophy" (1857). He contributed several biographical articles to the "Penny Cyclopædia," has been engaged as a

theatrical critic for the press for many years, has written several songs for music, and has furnished to the magazines translations of various German poems.

OXENSTIERN, or OXENSTJERNA, AXEL, count of, a Swedish statesman, born at Fanö, in Uppland, in 1588, died in 1654. He belonged to one of the most illustrious families of Sweden. After studying at the universities of Rostock, Wittenberg, and Jena, giving particular attention to theology, he visited most of the German courts, and in 1602 was recalled home to take the oath of allegiance to the new king Charles IX. In 1606 he was sent on a mission to Mecklenburg; in 1608 he was made a member of the senate, in which no fewer than 18 of his ancestors had held seats; and when the king became by old age incapacitated from ruling, he was chosen president of the council of regency. On the accession of Gustavus Adolphus in 1611 he was promoted to the chancellorship, the highest office in the kingdom, concluded a peace between Denmark and Sweden in 1613, accompanied the king to Livonia in his campaigns against the Russians, and in 1617 negotiated the treaty of Stolbova, by which Sweden gained a large territory along the Baltic. During the following years he was actively engaged in warlike operations or negotiations more or less connected with the 30 years' war, and in 1629, through the mediation of France and England, succeeded in concluding an armistice for 6 years between Sweden and Poland. He accompanied Gustavus Adolphus in his German campaign, and on the death of the king at Lützen in 1632 assumed the task of continuing the war. He was invested with full powers by the Swedish *Riksdag*, and elected, in the German Protestant assembly of Heilbronn, chief of the league against Austria. Nothing discouraged by the disastrous battle of Nördlingen in 1634, he evinced unwearied vigor in creating military resources and carrying on hostilities; and it was not until every thing had been placed on a safe footing in Germany that he returned to Sweden, to resume his duties as chancellor and act as one of the guardians of the young queen Christina. He was the actual ruler of Sweden during the queen's minority. He improved the finances, encouraged trade, and patronized learning; and when the sovereign became of age in 1645 the kingdom was in a most prosperous condition. For a few years Christina occasionally took advice from her chancellor; but the intrigues of the courtiers gradually undermined his influence, and his warnings proved ineffectual to prevent her from abdicating the throne in favor of her cousin Charles Gustavus. Oxenstiern was an accomplished scholar. Some of his writings, including his correspondence with his son during the negotiations which preceded the peace of Westphalia, have been printed. The 2d volume of the *Historia Belli Suevo-Germanici*, the first of which is from the pen of Chemnitz, is ascribed to him.

OXEYE, the trivial name of a syngenesious plant of the natural order of *compositae*, once called *duphthalmum*, a word of the same significance, but now known as *heliopeis laevis* (Persoon). The oxeye belongs to that natural section represented in the sunflower; it has rather large, many-flowered heads, the ray florets 10 or more, pistillate in a single series, those of the disk tubular and perfect; the receptacle conical; the smooth 4-angled achenia somewhat embraced by the lanceolate or linear chaff. It is a perennial herb with opposite, petioled, triply nerved, serrate leaves, and yellow flowers, found on banks of streams and in dry soils throughout the United States. Two or more varieties are known, and several intermediate forms. The sea oxeye (*borrichia frutescens*, De Candolle) is a low, shrubby, maritime, silky pubescent plant, with coriaceous or fleshy, opposite, nearly entire leaves, and solitary, peduncled, terminal heads of yellow flowers with blackish anthers, growing in Virginia and at the south. Another species is a shrub 5 to 10 feet high, the *B. arborescens* (De C.), found at Key West, Florida.—Quite a distinct plant, known as whiteweed, white daisy, or oxeye daisy (*leucanthemum vulgare*, De C.), is likewise sometimes called oxeye. It is a large, showy, troublesome weed, probably introduced from Europe, and spread far and wide over the mowing and grass fields of the United States, and seen also in Canada and Oregon. So rapidly and abundantly does it increase where it has found a hold, that in some regions the fields appear white when it is in full flower. It is considered as nearly worthless, though when cut with the hay crop horses and cattle will partake of it in their feed. In agriculture it is universally regarded as an intruder, and often defies every attempt to expel it, yielding only to an annual ploughing and cropping of the ground. There are two other species known, viz.: *L. integrifolium* (De C.), a dwarf, hairy plant, with spatulate linear leaves, and flowers with white, elliptical rays, seen on the shores of arctic America; and the *L. arcticum* (De C.), with a low, simple, nearly glabrous stem, 5 to 10 inches high, and with heads of flowers as large as those of the whiteweed, a plant extending in its range from arctic America southward to Hudson's bay and Fort Vancouver. The white oxeye or whiteweed is a representative of the *chrysanthemum*, some species of which (e. g., *C. segetum*, Linn.) are troublesome weeds in the fields of Europe.

OXFORD, a S. W. co. of Me., bordering on New Hampshire, watered by the Androscoggin, Saco, and other rivers; area, about 1,700 sq. m.; pop. in 1850, 39,768. Its surface is in some parts broken and mountainous, but the soil is generally fertile. There are several large lakes, of which Molechunkemunk, Parmachena, and many smaller ones, are wholly within the county, and Umbagog and Moose-lucmaguntic partly. The productions in 1850 were 227,439 bushels of Indian corn, 488,168

of potatoes, 146,266 of oats, 40,325 of wheat, 69,809 tons of hay, 156,853 lbs. of wool, and 837,475 of butter. There were 19 grist mills, 46 saw mills, 6 woollen factories, 4 founderies, 12 tanneries, 4 newspaper offices, 67 churches, and 18,051 pupils attending public schools. The county is traversed by the grand trunk railroad. Capital, Paris.

OXFORD. I. A township of Butler co., Ohio, on Four Mile creek, and on the Cincinnati and Indianapolis junction railroad, near the Indiana boundary; pop. in 1860 about 4,000. It contains a village of the same name, 33 m. N. W. from Cincinnati (pop. 1,500), noted as the seat of a university (see MIAMI UNIVERSITY) and other institutions of education. The western female seminary, situated $\frac{1}{2}$ m. S. E. of the village, has accommodations for 150 pupils and 10 teachers, and grounds comprising 80 acres. The school was established in 1853. The Oxford female college, incorporated in 1854, occupies a building 155 by 171 feet, 3 stories high, and accommodating 150 boarding pupils. The grounds embrace 85 acres on the hills overlooking Four Mile creek. The Oxford female institute is a boarding and day school. II. The capital of Lafayette co., Miss., on the Mississippi central railroad, 158 m. N. from Jackson. It is important as the seat of the state university, which was founded in 1848, and in 1860 had 10 instructors, 140 students, 222 alumni, and a library of 5,000 volumes. In 1850 there were 2 weekly newspapers and 2 churches.

OXFORD, an episcopal city and municipal and parliamentary borough of England, capital of Oxfordshire, situated on a gentle hill between the Cherwell and Isis, which here unite, 52 m. W. N. W. from London; pop. in 1851, 27,968. The ruins of an old wall, and the keep of a castle which now forms part of the gaol, show that it was formerly a place of some strength. Though irregularly built, with narrow, crooked streets and lanes and few good thoroughfares, its appearance from a distance, with its towers, spires, and stately public buildings rising among gardens and waters, is picturesque and imposing. The High street is less than $\frac{1}{2}$ of a mile long and of varying width, but nowhere exceeding 85 feet; but it is interesting for its architectural contrasts, the noble collegiate edifices alternating with quaint old dwelling houses and modern shops. Nearly all the avenues are clean and well paved and lighted, and of late years many new streets have been opened, and other improvements are constantly going on. The city has an abundant supply of good water. The rivers are crossed by several bridges, among which are the Folly bridge over the Isis, Magdalen bridge over the Cherwell, and the seven bridges, a succession of structures thrown across the Oxford canal and several small streams on the W. side of the city. The principal churches are the cathedral, which is the chapel of Christchurch college; St. Mary's, which serves as the university church,

and has a fine spire; St. Martin's, the "city church," with a clock tower and illuminated dial fronting the High street; St. Peter's in the East, a venerable Norman edifice lately restored; St. Mary Magdalene's, St. Giles's, St. Michael's, St. Aldate's, and All Saints'. In 1851 there were 82 places of worship, 23 public schools, and 58 private schools. The city possesses a free reading room and library, public baths, workhouses, a savings bank, a dispensary, the Radcliffe infirmary, a pauper lunatic asylum, a music hall, a town hall, a council chamber with an interesting collection of portraits, and a county hall and law courts erected in 1840 at a cost of £15,000. There are no manufactures, and, with the exception of a trade in the grain produced in the neighborhood, the city depends for support almost entirely upon the university. It has ready communication with other parts of the kingdom by means of the river, the Oxford canal, and the great western, a branch of the London and north-western, and the Oxford, Worcester, and Wolverhampton railways. It is governed by 10 aldermen and 80 councillors, one of whom is mayor; but in certain matters respecting the night police, markets, &c., the university authorities have coördinate jurisdiction. It returns 2 members to parliament, beside 2 returned by the university. The date of its foundation is unknown. It is mentioned as a seat of learning by Pope Martin II. in 802. Tradition says it was a favorite residence of Alfred the Great, and in modern history it is noted for the execution of Ridley, Latimer, and Crammer, and for the severity with which it was treated by the parliamentarians during the civil war.

OXFORD, UNIVERSITY OF, one of the two greatest seats of learning in Great Britain, was founded certainly as early as the reign of Edward the Confessor (1050), but the precise date is not known. Its origin, which has been ascribed without much probability to Alfred the Great, is traced to the monastic schools which existed there as appendages to various convents even before Alfred's time. Secular schools were soon established in imitation of these cloistral institutions. The teachers in time formed a voluntary association, dividing into different faculties the field of learning, and governed by a single house or legislature of which all the teachers were members. The students, who were generally poor boys, often mendicants, lodged in the town, or sheltered themselves in hovels or in the turrets of the city walls. Sometimes a number of them grouped together, hired an inn, hostel, or hall, and chose a graduate of one of the higher faculties to be their principal or guardian. The monasteries improved upon this plan by founding regularly endowed houses for the gratuitous support of poor scholars; and lastly, about the middle of the 13th century, independent colleges were founded under the plan of Walter de Merton, who made provision for the support of 20 poor scholars

at Oxford, setting apart for the purpose an estate in Surrey to be managed by bailiffs controlled by a warden and the scholars. The idea of adding to the literary character of these colleges the religious features of an ecclesiastical society originated with William of Wykeham, who established New college in 1386, and whose example was imitated by several others. The students or fellows were bound to a life of celibacy, and, after a 7 years' study of the arts, spent 12 more in preparing for a degree in theology, civil law, medicine, or astronomy. They then became doctors or professors, and were generally expected to vacate their fellowships. Fellows after obtaining the degree of M.A. were required to teach the subjects belonging to their faculty anywhere in the university. After a time commoners or non-foundation members were admitted to the course of instruction imparted by the fellows, and thus the whole plan of the university became changed. The fellows or foundation members received their fellowships after taking the first degree, and were no longer pupils but teachers; and the collegiate instruction was bestowed entirely upon commoners, who were never contemplated in the original foundation. The first charter of privileges to the university as a corporate body was granted by Henry III. about 1244. The first building for the university proper, that is, a school for all the colleges in common, was erected by Thomas Hokenorton, abbot of Oseney, in the beginning of the 15th century. In 1571 Elizabeth granted a charter of incorporation. In the time of James I. the university acquired the right of sending two members to parliament. In the civil wars it was distinguished for its loyalty to the house of Stuart, and under the protectorate was given over to the Presbyterians and Independents, who expelled a number of professors and masters of colleges, and appointed others "to reform its discipline and correct its doctrines." From the time of the restoration its history was marked by no important event until the passing of the Oxford university reform act in 1854. The well known hostility between the citizens and the students is of long standing, feuds of "town and gown" having broken out into riots as early as 1240. On several occasions the students were obliged to remove from Oxford. The most serious disturbance on record occurred on St. Scholastica's day, Feb. 10, 1855, when several lives were lost; and the bishop of Lincoln, in whose diocese Oxford then was, laid the townsmen under an interdict, from which they were only released in 1857 on condition that the commonalty should yearly cause a service to be said in St. Mary's church for the souls of those killed in the combat, and the mayor, the 2 bailiffs, and 60 of the principal burghers then offer in person at the great altar a penny each, or forfeit 200 marks a year to the university. This penance was subsequently mitigated, but not entirely remitted until 1825.—The present statutes of the university were

drawn up by Archbishop Laud in 1629, accepted by the university, and confirmed by patent from Charles I. in 1635. The corporation is styled "the chancellor, masters, and scholars of the university of Oxford." The chancellor is elected for life by the members of convocation, and for the last 200 years has been some nobleman of distinction, though he was originally an ecclesiastic and resident member. The present chancellor is the earl of Derby. The actual head is the vice-chancellor, who is nominated every year by the chancellor, and usually holds office 4 years by successive reappointments. He is selected from among the principals of colleges, and is a magistrate for Oxford, Oxfordshire, and Berkshire. The seneschallus, or high steward, is a nobleman nominated for life by the chancellor, and approved by the convocation. The enforcement of the rules is intrusted to 2 proctors, who are masters of arts chosen out of the several colleges in turn, and assisted by 4 pro-proctors. The public orator is an officer appointed by the convocation to write public letters and addresses, &c. The principal other officers are the keeper of the archives, assessor, registrar, librarians, keepers of the theatres, museums, galleries, observatory, &c., delegates of the press, of accounts, of appeals, of estates, and of privileges, and clerks of the markets. Connected with the university are 19 colleges and 5 halls, the latter differing from the former only in not being incorporated. These 24 establishments are quite distinct from the corporation of the university. Each is governed by a head elected for life, and styled principal, president, master, warden, rector, provost, or dean, and has its own statutes, though all the members are bound by the common rules of the university. The foundations of these colleges support 557 fellows, who correspond to the poor scholars of ancient times. Except at Wadham college, they have the option if they remain unmarried of retaining their fellowships for life or receiving a church benefice. Until the passing of the reform act of 1854 they were not required to reside at their colleges. Some of the fellowships are of small value; others are comparatively munificent, though by the founders' statutes they are expressly restricted to the poor; the possession of 10 marks (about \$33) was to vacate a fellowship at Brasenose. Fellows are generally chosen after receiving their bachelor's degree; they are the tutors of the college, and with the head constitute the corporate proprietors. The government of the university was formerly exercised by the heads of the colleges, who formed what was called the board of heads. Under the new reform act there are 8 legislative bodies: the hebdomadal council, consisting of the chancellor, vice-chancellor, 6 heads of colleges or halls, 6 professors of the university, and 6 members of convocation, having executive control, with the right of initiating new measures; the house of congregation, composed of all the principal officers of

the university, heads of colleges and halls, professors and assistants, public examiners, and all resident members, having the power to grant degrees, graces, and dispensations; and the house of convocation, consisting of the house of congregation with the addition of all masters of arts in their first year, and persons who have been regents, but have retired from the university. The last is engaged only with the more important affairs. Statutes framed by the hebdomadal council must be presented for approval to both the other boards.—The professors are 85 in number, viz.: regius professors of divinity, pastoral theology, Hebrew, Greek, civil law, medicine, ecclesiastical history, and modern history, Lady Margaret's professor of divinity, Saville's of astronomy, Saville's of geometry, Camden's of history, Laud's of Arabic, lord almoner's of Arabic, Linaire of physiology, Viner's of common law, Lord Litchfield's of clinical medicine, Aldrich's of chemistry, Boden of Sanscrit, Dean Ireland's of exegesis of Holy Scripture, the Radcliffe observer, and professors of botany, natural philosophy, moral philosophy, experimental philosophy, mineralogy, geology, political economy, rural economy, Latin literature, logic, poetry, modern European languages, Anglo-Saxon, and music. Attendance on their lectures however is not compulsory, and in point of fact the entire education of the students has been transferred from the university to the separate colleges. In these the fellows act as tutors, each one giving instruction in the whole curriculum of study. The result of this system has been the practical annihilation of the university proper, and the lowering of the standard of education to the level of the tutors, who are generally young men holding fellowships only until some better opening in life presents itself. Students are consequently obliged to resort to the aid of private tutors. The students are compelled to connect themselves with and reside in some college or hall. By the act of 1854, any master of arts was entitled to open a private hall under regulations to be made by the university; but this measure has proved inoperative. There are 4 terms, viz.: Michaelmas, from Oct. 10 to Dec. 17; Hilary, from Jan. 14 to the day before Palm Sunday; Easter, from the 10th day after Easter to the day before Whitsunday; and Trinity, from the Wednesday after Whitsunday to the Saturday after the first Tuesday in July. Before proceeding to the examination for the degree of B.A. a student must have kept 16 terms, unless he be a member of the peerage or the eldest son of a baronet or knight, in which case 12 terms are sufficient. Practically, however, terms are so reckoned that not more than 8 years' residence is required of anybody. Three public examinations have to be passed before obtaining the degree of B.A., and those who have distinguished themselves are distributed into 4 classes under the 4 great divisions of *littera humaniores*, *disciplina mathematica et phy-*

sica, scientia naturalis, and *jurisprudentia et historia moderna*. Since the agitation for university reform which led to the act of 1854, the range of studies has been considerably increased and the examination of candidates made stricter. By the same act all religious tests formerly required of students are abolished; headships, fellowships, and scholarships, formerly so restricted by the wills of founders in favor of certain classes, families, or locations, that out of the whole number of fellowships only 22 were open to public competition, are now mostly offered as rewards of merit; emoluments have been consolidated and redistributed, and colleges are empowered to alter and amend their statutes. The total revenue of the university from all sources is about £460,000 a year. Its separate revenue, apart from that of the colleges, and not including fees from students, is £7,500 a year, and its expenditure £7,000. The average income of heads of houses is £1,100, and of fellows £284. The professors are paid partly from the university funds and partly by foundation funds. The number of members on the books in 1854 was 6,259, and the number of students is about 1,800.—The principal university buildings are the schools, Bodleian library, theatre, Ashmolean museum, Clarendon, Radcliffe's library and observatory, university press, university galleries, Taylor institution, and university museum. The divinity school was completed about 1480. The Bodleian library, opened in 1602, occupies a fine room, and contains about 260,000 volumes. (See *BODLEIAN LIBRARY*.) The Ashmolean library was built in 1683 to receive a collection of rarities presented by Elias Ashmole. The Clarendon, built partly from the sale of Lord Clarendon's "History of the Rebellion," is used for various purposes; it was formerly the printing house. The Radcliffe library and observatory were founded under the will of Dr. John Radcliffe, who left for the former £40,000, beside £100 a year for the purchase of books, and £150 for the librarian. The books are all on medicine and natural history. The observatory comprises a dwelling house for the observer and a lecture room, and is well supplied with instruments. The printing house is an extensive quadrangular structure. The university galleries founded by the will of Dr. Randolph for the reception of the Pomfret statues, and the Taylor institution established by a bequest from Sir R. Taylor as a school of modern languages, form one handsome range of buildings designed by Mr. Cockerell. The new university museum, opened in 1860, is a magnificent quadrangular building in the mediæval style. The principal front contains apparatus and lecture rooms; one wing is devoted to the departments of anatomy, medicine, physiology, and zoology; another to those of chemistry, experimental philosophy, mineralogy, and geology, with a great lecture room; and the inner quadrangle, called the museum court, is intended

to contain the collections. The university also has a botanic garden of about 5 acres. University college, founded according to tradition by Alfred the Great and restored by William of Durham, who died in 1249, stands on the High street. Baliol college was founded by John Baliol, father of the Scottish king of that name, and by Devorguilla his wife, between 1263 and 1268. Merton college, founded at Malden, Surrey, in 1264, by Walter de Merton, and removed to Oxford in 1274, consists of 8 courts, and presents some of the most interesting specimens of ancient architecture in Oxford. Exeter college, founded in 1814 by Walter de Stapledon, bishop of Exeter, has a handsome front rebuilt in 1835, and a magnificent Gothic chapel completed in 1860. Oriel college was established by Edward II. in 1826; Queen's college, occupying 2 fine courts on the High street, by Robert Eglesfield, confessor to Queen Philippa, in 1840; New college, a remarkably beautiful Gothic edifice, by William of Wykeham in 1886; Lincoln college by Richard Fleming, bishop of Lincoln, in 1427; and All Souls' college, occupying 2 grand quadrangles, by Archbishop Chichele in 1487. The last is not engaged in education, having no members but the warden and fellows, with chaplains and clerks; but an effort is now (Jan. 1861) making to open it to students. Magdalen college, famous for its beautiful gardens and almost unrivalled in Oxford for its architecture, was founded by William of Waynesflete in 1456. Brasenose college was founded by William Smith, bishop of Lincoln, in 1509; and Corpus Christi college by Richard Fox, bishop of Winchester, in 1516. Christchurch college was originally established by Cardinal Wolsey in 1526 for a dean, sub-dean, 100 canons, 10 public readers, 18 chaplains, an organist, 12 clerks, and 18 choristers. Suppressed by Henry VIII. on the cardinal's disgrace, it was revived on a smaller scale in 1585, again suppressed in 1545, and reestablished in 1546 on the foundation of the see of Oxford as an appendage to the cathedral church. This is the largest and finest of all the colleges. Over the principal gateway rises a grand tower begun by Wolsey and finished in 1681 by Sir Christopher Wren, and containing "great Tom of Oxford," the famous bell, 17,000 pounds in weight, whose tolling summons all the scholars of the university to their respective colleges at 9 o'clock every night. The college has a picture gallery rich in works of the Italian masters, and enjoys the distinction of possessing the most splendid kitchen in Europe. Trinity college was founded in 1554 by Sir Thomas Pope; St. John's college in 1557 by Sir Thomas White; Jesus college in 1571 by Dr. Hugh Price; Wadham college, memorable as the birthplace of the royal society, by Nicholas Wadham in 1613; Pembroke college by Thomas Teedale in 1620; and Worcester college, originally called Gloucester hall, by Sir Thomas Cookes in 1714. St. Mary hall, originally the parsonage of St.

Mary's church, was converted to its present uses in 1833, but the buildings were substantially rebuilt in the 18th century. Magdalen hall was built adjoining Magdalen college about 1558, and became an independent academical hall about 1518. In 1822 the members removed to the buildings of the extinct Hertford college. New Inn hall, previously a part of New college, became independent in 1438. St. Alban hall, originally belonging to the nuns of Littlemore, was granted to Merton college in 1547, and soon afterward acquired a separate establishment. St. Edmund hall was devoted to academical purposes by the canons of Oseney in 1269; after the dissolution of monasteries it was transferred to Queen's college, and was reestablished as a hall in 1559.

OXFORD, EARL OF. See HARLEY, ROBERT.

OXFORDSHIRE, a S. county of England, bordered S. and S. W. for 70 m. by the river Thames or Isis, and enclosed by the counties of Warwick, Northampton, Buckingham, Berkshire, and Gloucester; area, 756 sq. m.; pop. in 1851, 170,386. It is very irregular in outline, having a breadth of from 7 to 38 m., and an extreme length of 50 m. The surface is extremely varied. In the S. E. are the Chiltern hills, offering most agreeable and diversified scenery and abounding in forests and tracts of fertile land; the central and N. portion, with the exception of a not very elevated ridge, are mostly flat, but well cultivated. The principal rivers are the Thames, or Isis (by which latter name it is known until it is joined by the Thame), the Evenlode, Windrush, and Owerwell. The soil is generally very fertile, and the population is principally engaged in agriculture, especially in dairy husbandry. The county has long enjoyed a reputation for its beautiful woods, and the abundance of its meadows and pastures. There are many interesting antiquarian remains. It sends 8 members to parliament, 3 for the county, 2 for the city of Oxford, 2 for the university, and 1 for Woodstock.

OXIDE OF CARBON. See CARBONIC OXIDE.

OXIDES. See OXYGEN, and NOMENCLATURE.

OXPECKER, a bird of the starling family, and the genus *buphaga* (Linn.), inhabiting the warm parts of Africa; it is also called "beef-eater." The bill is pincer-like, stout and broad at the base, with depressed culmen and curved tip; the wings long and pointed, the first quill very short and the third the longest; the tail long, broad, and wedge-shaped, with the end of each feather pointed; tarsi and toes robust, and the claws compressed, curved, and sharp. The best known species, *B. Africana* (Linn.), is between 8 and 9 inches long, reddish brown above and yellowish white below; the bill is yellowish, with a red tip. It is a shy bird, generally seen in flocks of 7 or 8, about herds of cattle, buffaloes, and antelopes, alighting on their backs and extracting the larvae of the botflies (*astrides*) which infest them; the bulging of the bill at the end is admirably adapted for

gently squeezing out these and other parasites from under the skin; this forms their chief food, and the cattle allow them to perch on their backs, as if conscious of their intended good offices. Another species, *B. erythrorhyncha* (Stanl.), has a red bill.

OXUS. See JIBOON.

OXYGEN (Gr. *oxus*, acid, and *γεννα*, to generate), an elementary gas discovered in 1774 by Priestley, and soon after by Scheele in Sweden and Lavoisier in France. It was named oxygen by Lavoisier because it was deemed the essential acidifying principle, and the name has since continued in use, although acids are known which contain no oxygen, and some of its compounds, as all the protoxides of the metals, have the properties of bases neutralizing acids with which they combine. The symbol of this gas is O, its equivalent 8, its specific gravity about 1,111, air being 1,000. When its compounds are decomposed by galvanic action it always appears at the positive pole, and it ranks as the most electro-negative of all bodies. It possesses neither taste, odor, color, nor acid reaction, and is not condensable by any degree of pressure and cold which we can command. No element is so universally diffused, and none plays a more important part in the economy of nature, in the animal, vegetable, and mineral kingdoms. It forms $\frac{1}{8}$ part of the air we breathe, and without it respiration would soon cease. (See ATMOSPHERE.) So essential is it to animal and vegetable life, that it has been termed the vital air. It is an element of water also, which is composed of 8 parts by weight of oxygen and 1 part of hydrogen. It is an ingredient of nearly all organic bodies; and all the earths, silica, magnesia, alumina, lime, &c., which constitute the principal portion of the rocks and soils, contain a large and definite proportion of oxygen, which gives to them the character of oxides. Though the gas is necessary to respiration, it cannot long be breathed with impunity undiluted. In the case of rabbits breathing it pure, the respiration after an hour or more becomes very rapid and the system generally highly excited. Debility and stupor succeed, and death occurs within 10 or 12 hours, the heart, however, still continuing to beat for some time after the breathing has ceased. The blood both in the veins and arteries is found to be highly florid. This stimulating property has suggested the application of oxygen or of the nitrous oxide gas, which is more rich in oxygen than common air, for inflating the lungs of persons recently drowned. The ordinary process of combustion is dependent upon oxygen, being the chemical union with oxygen of the body consumed; but the phenomena of light, heat, and fire attending combustion are also exhibited when some substances are consumed in chlorine, or in the vapors of bromine, iodine, or sulphur. Excepting fluorine, all bodies may be made to burn in oxygen; but with many the process goes on slowly, and the heat and light devel-

oped by rapid combustion, and which, as the term is commonly used, are essential to the process, are not perceived. A definite amount of heat is, however, evolved in this chemical change, and it is estimated for given quantities of many combustibles by Despretz and others, as described in FUEL. (See also COMBUSTION, and FLAME.) When the process is conducted in pure oxygen, even some of the metals commonly regarded as incombustible may be made to burn with wonderful brilliancy, and produce in their oxides genuine products of combustion. —Oxygen cannot be readily obtained by separating it from the nitrogen of the air, there being no method of absorbing the latter gas known. Boussingault (*Comptes rendus*, vol. xxx. p. 261, and *Annales de chimie physique* [8], vol. xxx. p. 5) has shown that baryta may be made use of to absorb oxygen, the mineral being at a low red heat. It is thus converted into peroxide of baryta, and this, when subjected to a still higher temperature or to a current of steam, gives up its second atom of oxygen in a free state. By the use of hydrate of baryta, it has been thought the gas could be advantageously procured in the large way. Oxygen is freely yielded by many of its solid compounds when these are exposed to high temperature. Priestley obtained it by heating the red precipitate, oxide of mercury, which was thus converted into metallic mercury and oxygen gas. The mineral black oxide of manganese is a cheap and convenient source of oxygen. It is coarsely pulverized and introduced into an iron bottle, to the neck of which an iron tube is tightly fitted. The bottle is then heated to redness, when the gas soon escapes through the tube. Three atoms of the peroxide of manganese, 3MnO_2 , are converted into the red oxide, $\text{MnO} + \text{Mn}_2\text{O}_3$, which remains in the retort, and 2 atoms of oxygen which escape. A pure ore of manganese should yield for each pound 1,400 cubic inches or a little more than 6 gallons of gas. The material preferred to all others for affording pure oxygen with little trouble is the salt chlorate of potash, which contains 89.2 per cent. of the gas, one atom combined with its potash, and 5 atoms with the chloric acid; thus, KO, ClO_3 . When this salt is heated in a glass flask over a spirit lamp, it melts and freely gives off all its oxygen, the residue being chloride of potassium, KCl . Half an ounce should thus afford 270 cubic inches of pure gas. The chemical decomposition was found by Mitscherlich to take place at a much lower temperature if some thoroughly dried metallic powders, as the black oxide of copper or the binoxide of manganese, are intermixed to the extent of about one third of the whole with the potash salt. —When oxygen unites with other bodies, the process is called oxidation; and the removing of oxygen from its compounds is called deoxidizing. Three kinds of oxides or binary compounds of oxygen and other elements are recognized: 1, acids, as the nitric, sulphuric, carbonic, and

many others, formed chiefly by the union of more than one equivalent of oxygen with one of an element usually non-metallic; 2, alkaline or basic, as soda, potash, lime, protoxide of iron, lead, &c., all combinations of an atom of oxygen with one of the metallic base; 3, neutral bodies, such as have neither acid nor alkaline properties, as water, the oxide of hydrogen, the nitrous oxide gas, the deutoxide of lead, &c.—By the action of the electric spark, or by the influence of phosphorus upon oxygen, a change is induced upon this element, and a substance is produced to which the name of ozone is given. (See Ozone.) Prof. Schönbein, who first made this observation, believes there are two kinds or allotropic modifications of active oxygen, which have the relations of + and —, or positive and negative, to each other, the one an ozone and the other an ant-ozone, which being brought together neutralize each other, and the product is inactive oxygen. The oxygen of many oxy-compounds, as the oxides of the precious metals, the peroxides of manganese, lead, cobalt, &c., he regards as wholly or in part of the negatively active character, or ozone proper, and he hence distinguishes these compounds as “ozonids;” while that of another series of oxy-compounds, as the peroxide of hydrogen, barium, strontium, and the rest of the alkaline metals, is of the opposite character, and the compounds he classes as “antozonids.” See his letter to Prof. Faraday in the “London, Dublin, and Edinburgh Philosophical Magazine,” vol. xvi. p. 178, and in the “American Journal of Science,” Jan. 1859.

OYER (law Fr. *oyer*, Lat. *auditus*, a hearing; from Lat. *audire*, to hear). When one of the parties to a suit declares on or otherwise pleads a deed, that is, an instrument under seal, and founds his claim or rests his defence upon it, he must generally make *profert* of it, or in other words, must aver in his pleadings that he produces the said writing in court. When pleadings were oral, that was strictly true; but now the party retains the instrument in his private custody until it is called for by his adversary. Of a writing so material to the suit of him who pleads it, the other has the right to know the tenor; and this he seeks by craving *oyer* of it. That would have been in the times of oral pleading literally a hearing; but now it is a reciting of the document, which spreads it on the record. Oyer will be granted or not to him who craves it, as he is or is not entitled to have it. In the first place, as to the occasion. Oyer is never granted except when *profert* is made. In the second place, as to the ground of awarding it, that is done on the consideration that the party who demands *oyer* cannot without it make intelligent answers to the claim which his opponent founds upon the instrument. Thus, for example, a plaintiff who pleads a deed is obliged to recite only so much of it as is directly material to his case; but if *oyer* of it be permitted to the defendant, he may be able to show that it is not a valid

instrument, or may find in it other matter which will serve him by way of answer. It is a general rule, that *profert* is required only of deeds, because they are regarded as the only private writing on which an action can be directly founded. In the case of bills of exchange and promissory notes, and other unsealed writings, the action is technically brought, not on the writings themselves, but on the contract of which they are the parol evidence. Yet, in practice, the court will order a copy of bills and notes to be furnished to the defendant before he is obliged to plead. *Profert* need not be made of wills or of public records, for they are not, properly speaking, such instruments as deeds are; but if an executor bring a suit, he must plead and make *profert* of his letters testamentary, for they furnish his authority and right of action, which process rests upon them. While in general one who pleads a deed and makes title under it must make *profert* of it, this rule goes on the presumption that he has the control of the instrument. It therefore admits exception when in fact the deed is in the hands of the opposite party, or has been destroyed by him, or when it has been lost or destroyed by accident. These defences must be specially pleaded; for if one make a formal *profert* without being able to produce the deed in fact, when *oyer* of it is demanded, his opponent may demand judgment against him.—The right to have *oyer* may be generally stated thus. It will be awarded when *profert* is necessary and is also made. If *profert* were necessary, but was not made, the opposing party cannot have it, but must demur to the pleadings as insufficient. Finally, if *profert* were unnecessary, but was nevertheless made, as for example by way of inducement, there is no right of *oyer*, because the party pleading makes no title under the instrument. One who has the right of *oyer* is not bound to exercise it; but if he propose to found his answer on any matter contained in a deed of which *profert* was made, he must demand *oyer* of it, and set it forth *verbatim* in his pleading.

OYER AND TERMINER, the technical name of a commission issuing in England from the crown, to certain judges of the courts of Westminster (usually with some other persons joined with them as commissioners), by virtue whereof they take jurisdiction over treasons, felonies, and misdemeanors. These words were used in the commission when it was written in Norman French; and in English the authority is to “inquire, hear, and determine.” This commission has been variously regulated in England at different times, by statute or by usage. A similar authority is given to the courts of criminal jurisdiction in the United States, usually by the statutes creating the courts and defining their powers; and this authority is of course limited in each case to the offences of which the court can take cognizance.

OYSTER, a well known marine acephalous mollusk, of the lamellibranchiate order, and ge-

nus *ostrea* (Linn.). The shells are very irregular, inequivalve, and lamellated, the right or upper shell being the smallest and flattest and moving forward with age, leaving a lengthening groove for the ligament exposed along the beak of the adhering valve, which is the left and lowest, the deepest and most capacious, and attached to foreign bodies by a calcareous growth from the shell itself; the shells are so variable in surface and shape that it would be difficult to describe them even if it were necessary, and for the same reason it is almost impossible strictly to define the limits of the species; there is only one adductor muscle to hold the valves together, and the small ligament at the hinge is inserted into a little depression on each side, without teeth or projecting plates. The animal is very simple; the mantle has a double fringe, and its lobes are widely separated, united only near the hinge; there is no vestige of foot; respiration is effected by means of vascular gills or membranous plates attached to the inner surface of the mantle, to which water is constantly brought by the ceaseless action of vibratile cilia; the mouth is jawless and toothless, but is provided with short labial processes separate from the gills for selecting food, consisting of minute particles brought to it by the respiratory currents; the intestine is comparatively short, with a few convolutions; the ventricle of the heart lies upon the rectum; by most writers oysters were considered hermaphrodite, but they are, according to Siebold and others, of separate sexes, though the females vastly preponderate, and are ovoviparous; they are sensible of light, as is known by their closing the valves when reached by the shadow of an approaching boat, and have numerous short pedunculated yellowish brown eyes between the fringes for more than $\frac{1}{4}$ of the length of the mantle. The adult oyster has no power of locomotion, and the only signs of vigorous movements are in the expulsion of the respiratory currents, the excrements, and the sperm or ova by the sudden closing of the valves and the contraction of the mantle; hence they have been considered as very low in the animal scale, and to be "as stupid as an oyster" has become a proverb; but it is said they can turn themselves if placed upside down, and the sensibility of the fringes and labial processes is acute. The eggs are expelled in a white, greasy, viscid fluid, called "spats" by the fishermen, which adhere to submarine bodies, and to each other, by their development forming the immense banks found upon some coasts, the old ones being destroyed by the pressure of the new; fecundation is effected through the medium of the water, which conveys the sperm to the ova; the eggs are to a certain extent developed within the cavity of the mantle about the gills; to this cavity also gain access the floating ova of some of the smaller crustacea, and here the little, soft, yellowish white crab (*pinnothera*) is often developed to a considerable size, as must be known to every lover of

oysters; this last is a parasitic inhabitant of the oyster shell, and is not a portion of its food, as the softness of the mouth of the latter does not admit of its attacking any resisting substance. Oysters are found in almost all seas, usually in from 2 to 6 fathoms of water, and never at a great distance from the shore; they are especially fond of tranquil waters or the gulfs formed by the mouths of great rivers; they cannot live in fresh water, but some species remain dry during the greater part of every tide; the tree oysters (*O. parasitica* and *polymorpha*), which attach themselves to mangrove and other bushes in the tropics, enclose within the shells a sufficient quantity of water to keep up the respiratory currents; this faculty, possessed more or less by all the family, renders practicable their transportation to great distances and facilitates the valuable trade thence resulting. This delicious bivalve has been highly esteemed as an article of food from the times of the ancient Greeks and Romans to the present day, whether in the fresh and raw state, cooked, or salted and pickled; they are of easy digestion, but not very nutritious, and act rather as a provocative to appetite by the saline water they contain in the raw state than as satisfying food; they are eaten all the year round, except in the months of May, June, July, and August, which is the spawning season; they are good even then, but it is fortunate that the supposition that they are then injurious, in addition to the difficulty of keeping them fresh during the heat of summer, comes in to allow them to breed and keep up a supply which otherwise might be locally exhausted, notwithstanding their great fecundity. The common oyster of Europe (*O. edulis*, Linn.), abundant on the coasts of Great Britain and France, occurs in large banks or beds, sometimes extending for miles, usually on rocky bottoms; from about the middle of August to the middle of May they are dredged from the bottom by a kind of iron rake drawn by a boat under full sail, several hundreds being taken at a single haul; these are transferred to artificial beds or parks in some favorable and accessible locality, where they are preserved for sale, continually growing in size and improving in flavor. The growth of the oyster is slow, it being only as large as a half dollar at the end of 4 to 6 months, and twice that size at the end of a year; in artificial beds the growth is usually slower, the full size not being attained till the 5th to the 7th year. The west coast of Scotland and the Hebrides have the best oysters of the British coast, and here in sheltered bays they acquire the green color so esteemed by the epicure, and supposed to be due to conferva and similar colored growths in the breeding places. It is estimated that 30,000 bushels of oysters from artificial beds, and 100,000 bushels of sea oysters, are annually sent to the London market; the Jersey fishery employs during the season 1,500 men and as many women and children, and between 400 and 500 vessels. The

oysters most esteemed in Paris come from the bay of Cancale in the English channel, and from the coasts of Brittany and Normandy. From the report to the French government, in 1859, of M. Coste, an eminent naturalist, who had been ordered to stock St. Brieuc bay with oysters, and who had accordingly planted 3,000 acres with 3,000,000 oysters, it appears that 20,000 of the size of $\frac{1}{4}$ of an inch were attached to a simple apparatus no larger than a wheat sheaf, which would be ready for the market in 18 months; this crop would be inexhaustible, as each adult furnishes between 2,000,000 and 3,000,000 embryo oysters; he estimates that he can cover 12,000 acres annually with oyster beds at an expense of \$2,000; believing it proved that industry guided by science may in this way form at the bottom of any sea not liable to the deposit of mud more abundant harvests than the earth affords, he proposes stocking the whole Atlantic and Mediterranean coasts of France, of Algeria and Corsica, and the salt ponds of the south of France.—The species most esteemed in America are the Virginian oyster (*O. Virginiana*, Lister) and the northern oyster (*O. borealis*, Lam.). In the *O. Virginiana* the shell is elongated and narrow, and the beaks pointed and not much curved; the surface of the smaller and upper valve when not worn presents everywhere leaf-like scales of a leaden color, and a lengthened pyramidal hinge-ridge along the beak; the muscular impression is nearly central, and of a dark chestnut or violet color; it often measures 12 to 15 inches in length, but is rarely more than 8 inches wide. This is the common oyster from Chesapeake bay southward; it is sometimes found in the vicinity of Boston, and also at the mouth of the river St. Lawrence; it multiplies so rapidly on some of the low shores of the southern states as to offer impediments to navigation, and to change the course of tidal currents. In the *O. borealis* the shell is more rounded and curved, with the beaks short and considerably curved; the surface is very irregular, presenting loosely arranged layers of a greenish color, with the margins more or less scalloped; the muscular impression is dark violet, and the interior chalky or greenish white; a common size is 5 or 6 inches in length, but it grows to the length of a foot and to a width of 6 inches. This is the common New York oyster, said also formerly to have been abundant in Massachusetts bay. Boston market is supplied principally from artificial beds derived from the Virginia and New York oysters; the flats in the vicinity of our large maritime cities are generally thickly beset with poles, indicating the localities of oyster beds. The oyster trade of Baltimore in 1860, exclusive of local consumption, was estimated to amount to \$3,500,000; and that of the whole of Chesapeake bay in 1858 at \$20,000,000, at the rate of \$1 per bushel. Many of the American forms resemble those of the *O. edulis* of Europe, and the fishermen generally regard them as the same. The successful experiments

of M. Coste, above referred to, merit a repetition in this country, and would doubtless in the same way open a new and profitable branch of industry to many of our seaports.—There are more than 60 species of oysters described in various parts of the world; those of tropical climates have generally a less delicious flavor than the natives of temperate zones; there have also lived about 200 species of fossil oysters from the time of the ammonites to the present epoch. The family *ostreada*, of which the oyster is the type, contains also the genus *anomia*, translucent, pearly white within, attached to rocks and weeds by a calcareous plug passing through a hole or notch in the right valve, the same species presenting a great variety of shapes from acquiring the form of the surface to which they are attached. Allied genera are *placuna*, like the *P. sella* or Hungarian saddle, and *P. placenta* of the Chinese seas, so transparent as to be used by the natives for glass in their windows; the *pecten* or scallop shell; and the *spondylus* or thorny oyster.

OYSTER CATCHER, a wading bird of the genus *hamatopus* (Linn.). The bill is twice as long as the head, and is strong, straight, much compressed, sharp-edged, and truncated at the end; wings long and pointed, with the 1st quill the longest; tail moderate and even; tarsi strong, covered with reticulated plates anteriorly; toes strong, enlarged on the sides by a thickened membrane, and the middle united to the outer by a basal membrane; hind toe wanting; claws strong, broad, and slightly curved. There are about a dozen species, distributed in most parts of the world; they are either solitary, or occur in small flocks on the sea shore or salt marshes, feeding on various bivalve mollusks, crustaceans, marine worms, and small fry, obtained from the retreating surf or dug from the mud and sand with the bill; they sometimes break the shells, pry them open or off the rocks with the compressed mandibles, or seize the soft bodies when the shells are gaping; they also suck sea urchins (*echini*). The flight is swift, strong, and long sustained during their migrations in large flocks; they are also good runners, swimmers, and divers. The American oyster catcher (*H. palliatus*, Temm.) is 17 $\frac{1}{4}$ inches long and 8 feet in alar extent; in the winter plumage the body above is light ashy brown, darker on the rump; the upper tail coverts and wide diagonal band on the wing white; under parts white; bill and lids bright orange red; legs pale reddish; both sexes are alike; the summer plumage is much darker. This species is found on the Atlantic coast from Labrador to Florida, never far inland or away from the salt water; it is very shy and vigilant; it goes north in the spring to breed, returning in October; the nest is made without care on the shingly beach in the scanty herbage above high water mark, in the sand or in the marshes; the eggs are 4, 2 $\frac{1}{4}$ by 1 $\frac{1}{4}$ inches, pale cream-colored,

with spots of brownish black and paler tints; the cry is loud, like the syllables "wheep, wheep, wheep;" the flesh is dark and tough, and not fit for food. A rather smaller and darker species (*H. niger*, Pallas) is found on the Pacific coast of America and N. E. Asia; the *H. ater* (Vieill.), from the west coast of South America, is 18 inches long, with brownish black plumage and bright red legs. The pied oyster catcher or sea pie (*H. ostralegus*, Linn.) of Europe much resembles the American bird, but is smaller, and has the bill less deep at the bulging part, less sharp-pointed, and proportionally shorter; it has similar habits, and may be readily domesticated, forming a handsome addition to the park or poultry yard.

OYSTER GREEN (*ulva latissima*, Linn.), a marine, annual plant of the class known as thalloids, having no distinct sexes and no separation of stems and leaves. It consists of an oblong, roundish, wavy, rich dark green, leaf-like expansion called the frond, which is affixed to stones, rocks, and mud at the bottom of the sea. The frond varies much in shape, being sinuated or wavy or flat, often plaited; and likewise in size, from 6 inches to 2 feet in length, and from 3 to 12 inches in breadth. Its substance consists of two layers of cells, imbedded in which are myriads of minute green granules (spores), which answer for seeds, arranged in fours over the whole frond. It is common on the American coast. The oyster green in Europe is served at table with lemon juice, and as a diet is esteemed good for scrofulous habits. Lightfoot in his *Flora Scotica* says that in the Shetland islands anodyne virtues are attributed to it, and that it is bound about the forehead and temples to assuage headache and to procure sleep. In America no use is made of it of which we are aware.

OYSTER PLANT, or SALSIFFY, a species of *tragopogon*, with smooth lance-linear leaves and heads of rather showy flowers, a native of Europe and cultivated in gardens as an esculent (*T. porrifolium*, Linn.). It has a stem 3 to 4 feet high, slightly forked branches, leaves 6 to 15 inches long, ovately dilated at base, and tapering upward to a point; the back of the leaf is also keeled; heads of flowers terminal on enlarged, hollow, club-shaped peduncles, the florets of a violet purple, and the achenia (seeds) about an inch long, lance-oblong, striate-furrowed, roughish, ending in a smooth, slender beak crowned with a tuft of bristles (*pappus*); the flowers appear in June and July. The root is fleshy and spindle-shaped, and when properly cooked possesses the flavor of fried oysters. A good, deep, mellow soil is needed for the cultivation of the oyster plant, as the

roots extend down far into the ground; the beds should be in an open situation, and the seeds sown in shallow drills, which are made 6 inches apart and covered about half an inch, raking the beds smoothly over afterward. On coming up, if the plants are too thick they should be thinned occasionally, allowing the rest to remain where they were sown. In the autumn, when the roots are dug, let them be exposed to the air for a few hours, and then pack them separately in dry sand, whence they may be taken for use during the winter.

OZARK, a S. co. of Mo., bordering on Arkansas, intersected by the North fork of White river, and watered by other branches of the same stream; area, about 1,550 sq. m.; pop. in 1856, 4,185, of whom 88 were slaves. Its surface is hilly and covered with large forests of pine, and the soil in the valleys and bordering streams is fertile. The productions in 1850 were 115,670 bushels of Indian corn, 5,090 of wheat, 6,280 of oats, 4,218 lbs. of wool, and 28,958 of butter. Capital, Rockbridge.

OZAUKEE, a S. E. co. of Wis., bordering on Lake Michigan, and drained by Milwaukee river and Cedar creek; area, 288 sq. m.; pop. in 1855, 12,978. It has a rolling and heavily timbered surface and fertile soil. It was formed out of Washington co. in 1858. Capital, Ozaukee.

OZONE (Gr. *oze*, to smell), a gaseous substance of questionable composition, first observed by Schönbein, and by him and other chemists supposed to be an allotropic modification of oxygen. It is produced when a succession of electric sparks is passed through atmospheric air or through dry oxygen, and again by the slow oxidation of phosphorus in a closed vial. A portion of the oxygen undergoes a change, the effect of which is perceived in a peculiar smell somewhat like that of chlorine. This altered portion of gas possesses more powerful oxidating properties than oxygen itself. Its presence is detected by its property of liberating iodine from its combination with the metals; a slip of paper moistened with starch and iodide of potassium, exposed to the air of a vessel containing the slightest admixture of ozone, immediately becomes blue from the liberated iodine meeting the starch. Ozone loses its active properties by exposure to heat a little above the boiling point. Some chemists have supposed that ozone is the peroxide of hydrogen, HO₂. The subject of ozone has been thoroughly reviewed in the work of H. Scutten, physician in chief of the hospital at Metz, entitled *L'ozone, ou recherches chimiques, météorologiques, physiologiques et médicales sur l'oxygène électrisé* (1857).

P

P, the 16th letter and the 12th consonant of the English alphabet. It is the leading or most prominent of the labial mutes, and is pronounced by closely compressing the lips until the breath is collected and then letting it issue. It has been supposed that the shape of P was originally designed to represent the position of the mouth viewed in profile when uttering it, but the resemblance is not very obvious, and would certainly not apply to the Greek Π (*pi*). More probably it is merely a corruption of Π, which appears from old inscriptions to have been originally written Π', or with one arm shorter than the other. The Greek form of Π has been preserved in the Russian and Gothic alphabets. P is frequently interchanged with B, and in English words of Teutonic origin corresponds as a rule to B in the root. The exceptions to this rule are very numerous, however, as Eng. *sleep*, Anglo-Saxon *slapan*, Mæso-Gothic *slepan*; and on the other hand, when P occurs in words of Greek or Latin derivation, it is found to be the same in the original language; thus, Eng. *paternal*, Lat. *pater*, Gr. *pater*. The dialects of upper Germany frequently pronounce B as P, and those of lower Germany make the contrary change. In Spanish the two letters are constantly confounded. In Runic writings the character representing the sound of P is almost identical with our B. The pure sound of P is found in none of the Semitic languages except the Ethiopian, its representative in Hebrew and Syriac being believed to partake more of the *ph* or *f*. It is common in Chinese, but wanting in Japanese. Beside *b* and *f*, this letter is also interchangeable with *m*, *v*, *pf*, *c*, *k*, *q*, *t*, and *pt*. Followed by *h*, it is equivalent to the Greek *phi* (*φ*), and pronounced *f*, as in *physic*. In some words borrowed from the Greek, as *psalm*, it is silent.—As an abbreviation in Latin inscriptions, P. stands for *Publius*, *proconsul*, *pontifex*, *pius*, *perpetuus*, *patriotus*, *pedes*, *pondo*, *posuit*, *ponendum*, *post*, &c. P.P. signifies *pater patria*, *pro pratore*, *propositus*, *primipilus*; P.O., *patres conscripti*. In numismatics, it is the mark of ancient coins struck at Dijon. The numerical value of P among the ancients has been variously explained. As the initial letter of *πεντε* it seems at first among the Greeks to have indicated 5; afterward it denoted 80. Among the Romans, according to Baronius, it stood for 7; but according to Ugucio it was equivalent to C, 100, and according to others to G, 400, or with a horizontal mark over it to 4,000, 40,000, or 400,000.

PACA, a rodent of the agouti family, the only well determined species of the genus *calogenys* (Ill.). In this genus the zygomatic arch is enormously developed, the superior maxillary

portion presenting a large hollow beneath, giving to the skull somewhat the appearance of that of a snapping turtle; the outside of the arch in the male is wrinkled and roughened with small wart-like confluent excrescences, growing rougher with age; the malar bone is deeper than long; the molars are longer than broad, the crowns having 4 or 5 deeply indenting folds of enamel, and the incisors are slender. The *C. paca* (Rengg.) is about 2 feet long, stout-bodied, with short limbs; the head is large and broad, with an obtuse hairy muzzle; the eyes large; the ears moderated and sparingly clothed with hair; feet naked below, 5-toed, the inner very small, and with broad nails except on the inner; the tail a naked fleshy tubercle. The hair is coarse, closely applied to the skin, of a brown color on the upper parts and limbs, and white below; 3, 4, or 5 longitudinal white bands on the sides, more or less broken up into spots; in some specimens the color is blackish brown above and yellowish white below, and in others more rufous. The mammae are 2 pairs, one pectoral, the other inguinal. The zygomatic cavity is lined by a continuation of the skin of the face, and opens externally on the cheek; its use is not well ascertained; beneath this is a cheek pouch, opening into the mouth in front of the molars. They inhabit South America from Cayenne to Paraguay, and are sometimes found in Peru east of the Andes, and in some of the West Indian islands. They are generally seen singly or in pairs on the borders of the forests and rivers after sunset, remaining concealed during the day in burrows which they dig like rabbits; the food consists of leaves, fruits, and tender plants, and sometimes sugar cane and melons; they are lively in their movements, and are good runners, swimmers, and divers; cleanly in habit, the flesh is fat and well flavored. A species is found fossil in the caves of Brazil.

PACA, WILLIAM, a signer of the American declaration of independence, born in Harford co., Md., Oct. 31, 1740, died in 1799. He was graduated at the college of Philadelphia in 1759, studied law at Annapolis, was admitted to the bar in 1764, and in 1771 was chosen a member of the provincial legislature. In this position he signaled himself by his opposition to the government, and was elected to the first and second continental congresses. The Maryland convention at first instructed him not to consent to the separation of the colonies from the mother country, but this restriction was taken off in June, 1776. On the adoption of the constitution of his native state he was made senator for two years. In 1778 he was

appointed chief judge of the superior court of Maryland, which office he held until 1780, when he became chief judge of the court of appeals in prize and admiralty cases. In 1782 he was elected governor of Maryland. In 1786 he sat in congress for a short time, and in the same year was reelected governor. He served in the state convention that ratified the federal constitution, and in 1789 was appointed judge of the district court of the United States for Maryland, which position he held till his death.

PACHA. See PASHA.

PACHACAMAC, RUINS OF, the remains of an ancient Peruvian city, covering a large area, situated 7 leagues from the city of Lima, near the modern town of Lurin. It was the sacred city of the supreme divinity of Peru, Pachacamac, and was distinguished for a magnificent temple dedicated to him. Its door was richly incrustated with corals and precious stones. The golden keys of this temple were given by Pizarro to the pilot Quintero, and were valued at 4,000 marks.

PACHECO, FRANCISCO, a Spanish painter and author, born in Seville in 1571, died in that city in 1654. Until the age of 40 he resided chiefly in Seville, and his reputation as a painter was purely local. Visiting Madrid and the Escorial in 1611, he conceived such enlarged ideas of art from the masterpieces of Titian and other great Italian painters, that upon his return to his native city he opened there an academy of painting on a more comprehensive scale than had previously been attempted in Spain; in this school, among other pupils, were educated Alonzo Cano and Velasquez, the latter of whom married the daughter of Pacheco. In 1618 he was appointed by the inquisition censor of the pictures exposed for sale in Seville, his chief duty being to see that none representing the nude human figure were sold. He made a second visit to Madrid in 1623, and among other works dressed, gilded, and painted for the duchess of Olivares a wooden statue of the Virgin by Juan Gomez de Mora; an employment which he seems to have included among his regular professional labors, from the fact that he wrote an essay on the subject, and at various times of his life colored and gilded statues. He passed his latter years in Seville, where his residence became the resort of men eminent in literature and art, and particularly of the Jesuits of that city, to whom he was indebted for copious materials and hints for the preparation of his *Arte de pintura* (4to., 1649), a work considered indispensable to the student of Spanish art. His paintings are rarely met with out of Spain. He executed several hundred portraits in crayon, including that of Cervantes.

PACHECO, JOAQUIN FRANCISCO, a Spanish author, journalist, and statesman, born in Ecija, in the province of Seville, Feb. 22, 1808. He was called to the bar in 1833, and establishing himself in Madrid, became connected with a variety of journals, including the *Bol-*

tin de jurisprudencia y legislacion, founded by himself in connection with Gerez Hernandez and Bravo-Murillo, and of which 4 volumes were published between 1835 and 1839. For a number of years subsequent to 1836 he was a member of the cortes, and in 1847 he held for a short time the position of prime minister. In 1851 he upheld the constitutional cause against Sartorius, and in 1854 he reentered the ministry. In 1855 he was sent to Rome as ambassador, and in the succeeding year visited England in the same capacity, but was recalled upon the return of Narvaez to power. In 1860 he was sent as ambassador to Mexico, but received his passports from the Juarez government in Jan., 1861 after it had taken possession of that city. He is the author of two dramas, *Alfredo* and *Las infantas de Lara*, of a volume of poems, a "History of the Cortes of 1837," "Lectures on Penal Law," and a "History of the Regency of Maria Christina."

PACHOMIUS, SAINT, the founder of the first organized monastic community, born in upper Egypt in 292, died in 348. He was by birth a pagan, but about the age of 20, while serving in the army, became a convert to Christianity. As soon as his term of military service was expired he placed himself under the direction of a hermit of the Thebaid named Palæmon, and afterward (340) retired to the island of Tabenna, where he founded a monastery. His disciples soon became numerous. They occupied different houses, each of which had its superior, and several houses combined formed a monastery which was ruled by an abbot. The whole body of monks, amounting at times to as many as 7,000, recognized a common superior, with whom they assembled regularly at Easter, beside meeting on Sundays in the oratory belonging to all the establishments. On the opposite bank of the Nile there was a convent for women founded by the sister of Pachomius, and governed by the same rules as those for the men. The rules of Pachomius were translated into Latin by St. Jerome, and are still extant. Several of his letters have also been preserved, and both may be found in Galland's *Bibliotheca Patrum* (1768).

PACHYDERMATA (Gr. *παχυς*, thick, and *δερμα*, skin), a group of herbivorous mammals, generally of large size and unwieldy appearance, with a thick skin, naked or sparingly covered with hair. Among its living members are the elephant, hippopotamus, rhinoceros, manatee, tapir, hog, and peccary, and among the extinct genera the mastodon, dinotherium, palæotherium, lophiodon, macrauchenia, and toxodon; the manatee forms the connecting link with the cetaceans, an affinity commenced in the wallowing hog and tapir, and continued in the almost aquatic dinotherium and hippopotamus; they are allied to ruminants by the fossil anoplotherium, and to rodents by the hyrax, while the hiatus between the rhinoceros, tapir, and elephant was filled by the extinct lophiodon, macrauchenia, palæotherium, and their allied genera.

In the present epoch the genera and species are few, but during the tertiary period they existed under a far greater variety of form; it is probable that through climatal changes and human agency the elephant and the hippopotamus will in a few centuries be exterminated like the dinotherium and the mastodon. In the system of Cuvier the pachyderms included all non-ruminating hoofed quadrupeds, divided into *proboscidea* (elephants), *solidungula* (horse, &c.), and ordinary pachyderms subdivided according to the odd or even number of the hoofs. Wagner makes sections: I., *anisodactyla*, with hoofs in a single series around the bottom of the foot, and with skin usually naked, including the 4 families of elephant, tapir, hippopotamus, and rhinoceros; II., *sygodactyla*, with two hoofed toes for walking and two others placed higher up, including the hog family; and III., *lamnunia*, with flattened nails instead of hoofs, including the hyrax family. According to Owen's cerebral system (see MAMMALIA), the pachyderms would comprise all the hoofed quadrupeds except the ruminants and solidungulates, with the addition of the sirenoide *mutulata*. Van der Hoeven combines the systems of Cuvier and Owen, as follows: order *pachydermata*, with phalanx I., *proboscidea*, with the elephant family; II., *perissodactyla*, with an odd number of toes, with the families *nasicornia* (rhinoceros), *lamnunia* (hyrax), *tapirina*, and *solidungula*; and III., *artiodactyla*, with even toes, including the hog and hippopotamus families. The skeleton is generally massive, indicating great strength but inactive habits; the thoracic cavity is enormous, in proportion to the great bulk and weight of the viscera; the limbs are robust, though adapted for running in the smaller members like the hog; there are no clavicles; the peculiarities of the skeleton and teeth are given in the articles devoted to the different animals. The stomach is generally simple, and the intestines very long and voluminous, in accordance with the bulky and vegetable character of their food; the brain is well developed, and the complexity of the convolutions ranks them with the sub-class *gyrencephala* of Owen, but, with the exception of the hog, below the ruminants and carnivora; the nasal apparatus is richly endowed with nerves, forming a delicate organ of touch, and in some of prehension. They occur in the warmer climates of all parts of the world, except Australia, both in the present and former epochs.

PACIFIC OCEAN, one of the five great basins into which geographers have divided the waters surrounding the continents. It is the greatest in extent, the latest known, and the most interesting in its physical features. Between long. 70° W. and 110° E., that is, for the space of 180°, or over one entire half of the globe, it covers the greater part of the earth's surface, from Behring's straits to the polar circle that separates it from the Antarctic ocean. If we except China and the N. E. coast of Asia, not only was this sea itself unknown

before the time of Columbus, but the countries that bound it, including the vast coast line of North and South America on the E., and the Philippines, New Guinea, Australia, and Tasmania (Van Diemen's Land) on the W., were unvisited by Europeans. Humboldt speaks of its discovery as the most important cosmical occurrence, after the rediscovery of the American continent and the knowledge of its extension in the direction of the meridian from Hudson's bay to Cape Horn. Writers on physical geography have observed that the Pacific ocean presents, in the forms of the shores which bound it, some remarkable traits of resemblance to the Atlantic ocean. The W. coast of South America, says Romme, projects much like the W. coast of Africa S. of the equator. The gulf of Panama and the coast of Mexico have formations which offer some similitude with those of the gulf of Guinea and the promontory of Africa; the Caribbean sea, which runs up into the E. coast of Mexico, seems to correspond to the gulf which is contained between the N. coast of New Holland and the coasts of China, that gulf in which lie the Moluccas, the Philippine islands, &c. Nevertheless, the two oceans, in their other divisions, whether N. or S. of the line, differ much in their shores. The most obvious division of the Pacific ocean is that made by the equatorial circle into north and south; but in order to facilitate our brief study of this sea, we shall follow the example of Kerhallet and separate these two simple divisions by interposing a third, the equatorial Pacific ocean, which will embrace all the space comprised between the tropics of Capricorn and Cancer.—DISCOVERY AND EARLY NAVIGATION. The Spaniard Balboa obtained the first sight of the South sea from the summit of the Sierra de Quarequa, on the isthmus of Panama, Sept. 29, 1513. Columbus, in sailing along the coast of Veragua, had already received distinct accounts of a sea to the westward of that land, "which would conduct in less than 9 days' voyage to the Oheronesus Aurea of Ptolemy, and to the mouth of the Ganges." ("Cosmos.") Balboa, after

with eagle eyes
He stared at the Pacific, and all his men
Looked at each other with a wild surmise,
Silent, upon a peak in Darien,

rushed to the shore, and, drawing his sword, waded into the water, and took possession of the ocean before him in the name of the government of Castile. Immediately after he had announced his discovery to his sovereign, orders were issued by the Spanish government to navigate its eastern coasts in that vicinity, with a special view to the discovery of an opening between the Atlantic and Pacific oceans. Prominent among those who were engaged in this service was the celebrated navigator Juan Diaz de Solis. Although the Pacific ocean was discovered by the Spaniards, who navigated a limited portion of its American coast, it was first traversed by the famous Portuguese navi-

gator Magalhaens, 8 years after its discovery. It is a circumstance that seems now almost incredible that he should have crossed from America to Asia, and sailed over the whole ocean, a distance of 10,000 miles, without falling in with any other lands than two small uninhabited islands, until he discovered first the Ladrões, and afterward that very important and thickly inhabited group, the Western Isles, or the archipelago of Saint Lazarus; a name which the Spanish historian Martinez de Zuñiga tells us was changed to the Philippine Islands, by Ruy Lopez de Villalobos, in compliment to Philip II. After the murder of Magalhaens in the island of Mactan, Juan Sebastian Cano completed the first circumnavigation of the globe, in the ship appropriately named Victoria, and received for his armorial bearings a terrestrial globe with the inscription: *Primus circumdedisti me*. Balboa found the pacific reputation of the central part of this ocean fully established among the natives of Veragua and the isthmus, but the name was first given to it by Magalhaens; and the name seems by no means unnatural to one who has passed from the stormy regions of Terra del Fuego into the mild and genial climate of that part of the Pacific. Magalhaens could only have referred to the tropical portion, for in the first part of his navigation from the strait he experienced much stormy weather; the latitude of 32° 20' S. was observed Dec. 18, 21 days after leaving Cape Deseado. The term South sea has also been applied to this ocean, but neither of these names is more applicable or less absurd than the other. Malte-Brun, Kerhallet, and other writers have proposed to substitute for these the appropriate title of the Great ocean; but that of Pacific is now so firmly established and universally employed, that it is not likely to be supplanted. The error of Ptolemy with regard to the size of the old continent prevailed up to the epoch of which we are writing. It was generally believed that it occupied an extent of 180° of longitude, and spread over one half of the globe. Columbus, laboring under this transmitted misapprehension, enlarged this extent to 240°, actually filling up the North Pacific ocean with the continent of Asia, the E. coast of which was brought forward, in his conclusion, as far as the meridian of San Diego. The famous physician and astronomer, Paul Toscanelli, in his correspondence with Columbus, went even further than this, and reduced the distance by sea from the E. to the W. coast of the old world to 52° of longitude only. But the discoveries of Balboa, Magalhaens, and their successors, rapidly dispelled these erroneous notions concerning the divisions of the earth's surface, and introduced more correct, though still far from exact, ideas of the relative proportions of land and water. From that period to the present day, the Pacific ocean has presented a rich field for the labors and enterprise of navigators and discoverers. The progress of discovery in the south, how-

ever, was slow. The minds of men were for a long time persuaded of the existence of a *terra incognita*, or a *terra nondum cognita*, of immense extent. The magnificent promises of Quiros, in his memorial to the king of Spain (1612), embraced the discovery of an "unknown country, the fifth part of the terrestrial globe, which extendeth itself to such length, that in probability it is twice greater in kingdoms and seignories than all that which at this day doth acknowledge subjection and obedience to your majesty, and which," he adds, "must by proportion and analogy prove some terrestrial paradise." He challenges the investigation of mathematicians, offering to prove to them the existence of the continent, and calls it the world of which Spain is the centre. During the century and a half subsequent to the unsuccessful voyages of this enthusiastic navigator, the notion was steadily maintained that a continent existed somewhere in the southern seas. It was encouraged from time to time by the reports of successive navigators and the arguments of learned writers. Of the former, contradicted or corrected as they have been by the thorough examination of English navigators, it is unnecessary to speak. It is worthy of remark, however, that this portion of the history of navigation is an interesting exhibition of the progressive steps by which a knowledge of the earth's surface has been acquired, and forms a proper introduction to the voyages of Cook, whose genius, remarkably national in its traits, entitles him to the second place after Columbus as a bold and successful discoverer. The arguments of learned writers, to which we have referred, may be found in the appendix of Dr. Heylin's "*Cosmographie in four Books*," &c. (1677); *Histoire des navigations aux terres australes*, by Charles de Brosses (1756); the preliminary discourse of M. de Bougainville (*Voyage autour du monde*, 1771); "An Account of the Discoveries made in the South Pacific Ocean previous to 1764," part 1; "Investigations, &c., of Mr. Alexander Dalrymple;" and in the *Lettre sur les progrès des sciences* of Maupertuis (Berlin, 1752). Maupertuis suggests that the similarity in animal, vegetable, and mineral productions of the known world may be accounted for by the neighborhood or contiguity of the continents; but as the supposed southern continent is distinctly separated from the others, "the discovery of these countries would probably present great advantages to commerce, and wonderful novelties in the physical world." We cannot forbear adding another sentence from this letter, displaying the credulity of the times, and the zeal of the writer: "It is in the islands of this sea that navigators assure us that they have seen savages, hairy or shaggy men, with tails, a species somewhere between us and monkeys. I would rather have an hour's conversation with them than with the finest wit in Europe." Buache in 1754 published an atlas in which two con-

tinents were delineated, and he gravely assures the student that it will be found upon better acquaintance that one of them has a range of mountains extending along the coast similar to the Cordilleras of South America. His only authority for these continents was some small portions of New Zealand, and some islands the very existence of which was doubtful. The remainder was filled up by the pen guided by his imagination. The main argument of these writers is deduced from a consideration of the weight of land compared with that of water, from which it was concluded "that a continent is wanting on the south side of the equator, to counterpoise the land on the north, and to maintain the equilibrium necessary to the earth's motion." It is unnecessary to say that this reasoning attaches too much consequence to the inequalities upon the earth's surface, which in their proportion to the whole mass have no claim to such grave consideration. This is true of the ocean probably, as well as of the land. Laplace concludes, from a variety of reasons, that the depth of the sea is not very great anywhere, not materially surpassing the height of mountains on land; and as mountains and valleys form the surfaces of continents, the bottoms of the ocean are marked with the same irregularities. Further, although geometers have shown that the earth's centre of gravity, or centre of rotation, is nearly correspondent to its centre of figure, yet a slight defect in this correspondence may perhaps account for some of the lunar perturbations whose cause is now unknown. "Astronomically speaking," says Sir John Herschel, "the fact of the divisibility of the globe into an oceanic and a terrestrial hemisphere is important, as demonstrative of a want of absolute equality in the density of the solid material of the two hemispheres;" and he adds that this fact should not be neglected in any future investigation, which may attempt to explain the local deviations of the intensity of gravity from what is required by the hypothesis of an exact elliptic figure. This problem was not completely solved until the time of Cook, or we might say until the recent voyage of the younger Ross. Even up to a period so late that we may speak of it as our own day, various remote parts of the Pacific have rewarded the bold and patient navigator with new discoveries. And now a great deal still remains to be done to render its navigation secure, more particularly where new channels of commerce have been opened by the settlement of the N. W. coast of America and the continent of Australia. It may be thought that we have dwelt longer upon this part of our subject than its importance merits, but we are desirous of preserving, and of laying before the reader, these curious illustrations of a period when, as Humboldt says, "men's heads were dizzy with strenuous efforts, heroic achievements, deeds of violence, and discoveries by sea and land." At the beginning of this

period, "it was not only a hemisphere, but almost two thirds of the surface of the globe, which was then still an unknown and unexplored world; as unseen as that half of the moon's disk which the laws of gravitation withdraw for ever from the view of the inhabitants of the earth."—COASTS AND ISLANDS. The coasts which bound the Pacific ocean on the east and west are singularly contrasted with each other. That of America is in general a bold shore, on which the deep water advances near the land, while precipitous mountains overhang the borders of the sea. The eastern boundary of Patagonia presents a surface broken by innumerable islands, and filled with sounds and bays; but from the N. extremity of the island of Chiloe, on the parallel of 42° S., there are but few deep and sheltered bays, while the general character of the coast is such as we have above described. To the N. and W. of Panama we find the gulfs of Nicoya and Fonseca, and still more the gulf of California, presenting exceptions to our general description; but it is not till we have arrived at Puget sound, the neighborhood of Vancouver's island and the British territory, that the broken and indented forms of the Patagonian coast are renewed. On the coast of Asia, from the peninsula of Kamtschatka and the sea of Okhotsk to the continent of Australia, the coast line is so much broken up by seas and straits, by islands innumerable, varying in size, shape, and outline of shore, collected into groups and standing singly, that it is impossible to offer a description that will be applicable to any considerable portion of it. Here the navigator finds his path tortuous and intricate, but not so dangerous as might at first appear; for as this is the part of the world toward which during the last three centuries the commerce of the western nations of Europe has directed its energies, the charts and other means of navigation have been correspondingly improved. The Pacific ocean is distinguished by various groups of islands, occupying its central and eastern divisions, which are included under the general name of Polynesia. (See POLYNESIA.) The most important groups excluded from this classification are those of the Aleutian or Fox islands, and New Zealand.—WINDS. In speaking of the winds of the Pacific ocean, we shall take up first the central, intertropical, or equatorial division. Until a recent period it was supposed that the trade winds prevailed throughout this whole belt, with no other changes than those peculiar to themselves—the modifications, that is, due to the change of seasons. But numerous and accurate observations have established the fact that the trade winds blow constantly over less than one half of this belt. The S. E. trades are found all the year round only between the longitude of the Galapagos islands and that of the Marquesas islands; and the N. E. trades only between the meridian of 115° W. and the Mariana or Ladrone islands. The numerous groups of islands lying between

the Marquesas group and Australia are visited by periodical winds, which have more nearly the character of monsoons than trade winds; and the same may be said of the corresponding part of the ocean in the northern hemisphere. In the latter, the trade wind prevails only from the month of October till the month of May; in the former from March till October; during the rest of the year the wind changes to the west, and is accompanied with squalls and rains. The polar and equatorial limits of the trade winds are variable on both sides of the equator, the variation depending upon the sun's declination. Between these limits is a belt of variable winds, which is narrower in the winter than in the summer of the northern hemisphere. The average breadth of this belt is 5°, and it is contained between the parallels of 8° and 3° N.; sometimes, however, it disappears entirely, and the N. E. and S. E. trade winds are not separated from each other even by calms. In the month of May La Pérouse left the S. E. trades in lat. 5° 49' N., and took the N. E. trades in lat. 6° 10' N.; in the month of April the French frigate *La Poursuivante*, going from Tahiti to the Sandwich islands, crossed the line in long. 141° 40' W., and passed, without having any calms, from the S. E. winds to the N. E. in lat. 8° N.; and again in the month of July, the ship *Alabama*, going from San Francisco to Tahiti, and crossing the line in long. 127° 40' W., left the N. E. winds in lat. 7° 41' N., and caught the S. E. in the same latitude. There are several other examples of the same fact in the months of June, April, and February, for vessels crossing the line between the meridians of 144° and 155° W. Kerhallet, in his admirable memoir, gives a table showing according to the month the limit of the trade winds, and the breadth of the zone of the variable winds of the equator, compiled from the voyages of all the most celebrated navigators, from Cook to Fitzroy and Wilkes. When the sun is in the northern hemisphere, the N. E. trade winds vary from E. to E. N. E., and are frequently squally, with rain; on the contrary, when the sun is in the southern hemisphere, the trade winds take a more northerly direction, varying from E. N. E. to N. N. E.; these winds are less steady than the S. E. trade winds, and are more subject to calms and squalls. The periodical winds peculiar to the equatorial zone have been called by Krusenstern, Romme, and others, monsoons; but they do not, in fact, like the monsoons of the Indian ocean, blow from opposite points of the compass, neither are they equally regular in their recurrence. W. and S. W. monsoons are met with in all the archipelagos of the South Pacific ocean, from those of Nukahiva and Pomotou to the Solomon islands and New Guinea. In precisely this same region, between the months of November and April, hurricanes are experienced, especially in the vicinity of the New Hebrides and New Caledonia. But the hurricanes of the Pacific ocean are not so much to be dreaded as

those of the Indian and Atlantic oceans; they occur more frequently near the islands than in the open sea; and intervals of several years often pass without their being felt. These hurricanes, like those of the Indian ocean, are revolving storms, obeying a general motion of translation in a parabolic curve, of which the summit is tangent to the meridian in about lat. 26°, and of which the branches open toward the east. North of the equator, in this zone, the Ladrone islands are sometimes ravaged by hurricanes; and Capt. Hunter, of the ship *Japan*, in 1832 encountered one of these storms in lat. 13° N., and as far E. as the meridian of the Sandwich islands. Our other two divisions of this ocean, the North and South, comprehend the temperate zones of the two hemispheres; and it may be said in general of both of them, that the winds blow from all directions in all seasons of the year. But the westerly are the prevailing winds, blowing with more or less violence, and verging toward the pole in the winter, and the equator in the summer, of their respective climates. In the vicinity of Cape Horn the W. winds prevail during the greater part of the year; the same is true also of the coasts of Patagonia and Terra del Fuego. In the bay of Panama the winds vary from E. to N., from September to March; during the rest of the year they blow from S. to S. W. From the W. extremity of the bay of Panama to lat. 30° N., that is, along the coasts of Central America, Mexico, and Lower California, we meet again with periodical winds, to which the name of monsoons has been given, and which are disturbed by tornadoes, sudden gusts, or violent winds, known under the names of *vendavales*, *tapayaguas*, *papagayos*, *tehuantepec*, and *cordonzos*. In the months of February and March, between the parallels of 18° and 15°, prolonged calms take place, which may be compared to those of the gulf of Guinea; they have been known to last 30 days, at a distance of more than a degree from the coast. From San Francisco to Vancouver's island, the prevailing winds are north-westerly, particularly in the months of June, September, and October. At New Archangel, situated in lat. 57° 3' N., it is E. winds, according to Krusenstern and Hagemeister, that bring the rain and snow of winter. Leaving the N. W. coast of America, and entering the water space bounded E. by this coast, W. by Kamtschatka, N. by Behring's straits, and S. by the Aleutian archipelago, we find, according to Lütke, that the winds are very variable, those from the S. and S. W. predominating. On the immediate coast of the Russian peninsula the W. winds prevail during the winter, and the E. during the summer. Cook, who remained in this vicinity from May to November, confirms this statement. The sea of Okhotsk possesses, as might be expected, a climate peculiar to itself. The E. winds are almost constant in this sea, the occurrence of W. winds being rare. Two regular monsoons of unequal duration divide

the year on the coast of Tartary, in the islands of Japan, and on the N. coast of China. In the belt occupied by these monsoons the rainy season is the period of the S. W. monsoon for all the coasts having a westward exposure, and of the N. E. monsoon for those looking E., the reverse being the case for the dry seasons. But the most characteristic meteorological feature of this region is that frightful rotatory tempest, the typhoon, which may occur at all seasons, and is felt as far E. as the vicinity of the Ladrone islands. These hurricanes, which carry terror to the seaman, are usually announced by several indications, the most certain of which is the falling of the mercury in the barometer. The monsoons in the Philippine islands are subject to nearly the same laws as those of the China sea, changing, however, with less regularity. Around the island of Luzon are experienced, between July and September, storms peculiar to this climate, called *tempestades* by the Spaniards, and *vaquios* by the Indians, the precursory signs of which are given by Legentil. On the E. coast of Australia, S. of the tropic, and Tasmania, the N. W. winds reign between the months of October and April, but during the remainder of the year the S. E. winds are very frequent. Finally, the seaman is not exempt from the so called white squalls, which give no warning of their approach. They are most common between the tropics. Near the land, and particularly close to mountainous and elevated regions, they resemble whirlwinds, and electricity seems to play an important part in their origination, as it does in that of the water spouts frequently encountered in the Pacific ocean among the archipelagos, and on the coasts of China and Japan.—CURRENTS. Capt. Duperrey, in his chart of the motions of the waters in the great southern ocean, took the first step toward a collation of the scattered observations of navigators on the currents of the Pacific. Berghaus extended and generalized this work, which Johnston has brought as near to completion as the existing state of our knowledge admits. Without stopping to discuss the origin and causes of these currents—the effects of changes in specific gravity and temperature, of the diurnal motion of the earth, of the forms and positions of the continents—concerning which philosophers are still divided, we will proceed to give a brief description of the circulation which keeps in motion the waters of this vast domain of the sea, endeavoring to do it in a manner so simple that the reader will find no difficulty in tracing the directions upon a common atlas or globe. Dividing the ocean, for the consideration of this subject, into two parts by the equator, we shall commence with the currents of the South Pacific. Near the southern point of Tasmania, a current takes its origin from the combined influences of the warm current of the E. coast and the cold current of the S. coast of Australia, and from this point traverses the Pacific ocean, widening as it pro-

ceeds, until it approaches the W. coast of America, in the meridian of 98° W., where it divides itself into two principal branches. The northern branch continues its easterly course, inclining to the north, till it reaches the meridian of 78° , where, turning suddenly to the north, it takes the name of the current of Mentor, which it retains until it is lost in the equatorial current. The other, or southern branch, the largest in extent and the lowest in temperature, undergoes a further subdivision, one part running along the W. coast of America to the north, where it is known as the cold current of the coast of Peru, or Humboldt's current; the other part, turning toward the south, and washing that portion of the American coast, forms the cold current of Cape Horn, and doubling that cape, penetrates into the Atlantic. The temperature of the great cross current of the South Pacific varies with the latitude; in lat. 60° S. its temperature falls as low as 38° F., and even in lat. 85° it has not risen above twice this value, that is, 66° . The temperature of the current of Mentor rises as high as 72° , while the colder current of Humboldt has only obtained the temperature of 65° as far N. as the parallel of Lima. Very near the coasts of Chili and Peru, and following the sinuosities of the land, there is found a southerly current, which is in fact the counter current of Humboldt; it runs with a velocity varying from 3 to 12 m. a day. We shall give the velocities of the principal currents collectively in a table. The Pacific ocean, like the Atlantic, is traversed throughout its whole breadth by an equatorial current, which in the southern ocean is turned to the westward from the coast of Peru by the projection of the continent in the vicinity of Cape Blanco. In order to develop the leading features of this current satisfactorily, we will separate it into two branches—a separation which nature has already made by the equatorial counter current. The southern equatorial current makes itself first felt about the meridian of 88° W. Its limits are, on one side, N. of the tropic of Capricorn, and on the other S. of Pitcairn's island, and these limits are preserved till it reaches the archipelago of Tonga. In the neighborhood of this archipelago the hitherto united waters branch off in several directions. One stream, to which the name of Rossel's current has been given, pursues its W. course steadily through the labyrinth of islands until it reaches New Guinea and Torres strait, retaining its high temperature of 78° . Another branch descends along the E. coast of Australia as far as Tasmania; it is known as the warm current of the E. coast of Australia, is one of the sources of the cross current of the Pacific ocean, and brings us back, the reader will observe, to the point from which we started. The high temperature of this current, which near the land exceeds 68° F., in the latitude of Port Jackson, constitutes a very important feature of the climate of New South Wales, as in the case of the Gulf stream and the

southern Atlantic states.—The northern equatorial current begins to be felt about the meridian of 128° W., and on the parallel of 24° N., a limit which it maintains even up to the island of Loo Choo, in the meridian of 127° E., notwithstanding that it makes a deep bend to the southward, W. of the Sandwich islands. The temperature of this current varies from 74° on its northern limit to 88° on its southern; the mean temperature may be set down at 81°. This equatorial current of the north is separated from that of the south, particularly between the meridians of 115° and 150° W., by an equatorial counter current running to the east, and contained between the parallels of 5° and 10° N. The counter current is sometimes found further E. than laid down by Johnston. The Bonite, in 1886, encountered it in long. 100° W., and M. Darondeau has assigned to it a maximum velocity of 84 m. in 24 hours. The facts with regard to this counter current are not, it must be admitted, well ascertained; different limits have been assigned it by different navigators, and much remains to be done to make it as useful as it might be to seamen. Another easterly current has been discovered W. of the Sandwich islands, and in their latitude, which Johnston has called the "entanglement of the easterly current." Its existence is established beyond a doubt by the observations of Freycinet, Beechey, and Lütke. Still another curious perturbation of the equatorial current occurs in that immense series of cretaceous groups known by the general name of the Caroline islands; it is distinguished as the monsoon current, because it owes its existence to the alternate trade winds and monsoons of the China sea, from which it derives a corresponding change of direction. We have already spoken of two of the offshoots of the great equatorial current, the Rossel and the warm current of Australia; we are now to speak of a third, the current of the E. coast of Japan. The French call it after M. de Tesson, who during the voyage of the Venus completed the observations upon temperature commenced by Krusenstern. The Japanese give it the name of *kuro-siwo*, or black stream, derived from the dark color of its waters. Lieut. Silas Bent, U. S. N., read a paper on this stream before the American geographical and statistical society, in Jan. 1856. He calls it a "river in the ocean, flowing to the northward and eastward along the coast of Asia, corresponding in every essential point with the Gulf stream of the Atlantic." After traversing the eastern shores of the empire of Japan, it separates into two branches, one of which, continuing its north-easterly course toward Behring's straits, forms the current of Kamtschatka; the other, directed toward the east, preserves its original name until it finally disappears in the neighborhood of the N. W. coast of America, in about the meridian of 145° W. Near the tropic, where it comes almost in contact with the northern equatorial current, it has a temperature of 77°

or 78°, but in lat. 43° or 44° it sinks down to 55° or 56°. Its northern limit is marked, however, by a slight fall of temperature, which is afterward maintained as far as the Russian peninsula. Thus it appears that the waters which wash the Asiatic shores in this vicinity are comparatively warm; and this statement receives further confirmation from the fact that the sea never freezes in this region, notwithstanding the intense cold. This warmth is due to the current of Kamtschatka, which we have just seen is a branch of the Japan current. M. de Tesson found a temperature of 52° as high as Petropavlovsk; and Capt. Wilkes obtained 50° and 51° in lat. 60°, and even in Behring's straits, into which the waters of this current may be said to overflow. There is also a current descending in a S. and W. direction from Behring's straits, which spreads over the Aleutian islands, and runs through their channels and narrow straits with considerable velocity. In the E. part of the North Pacific ocean, between lat. 25° and 40° and long. 188° and 155°, occurs a singular phenomenon, to which Johnston has given the name of Fleuriu's whirlpool, because that hydrographer first pointed it out in his narrative of the voyage of Marchand. It has an E. and W. direction, and turns like the hands of a watch, the irregular circle which it describes being nearly of a radius of 240 m. Its existence is explained by the conflict between the waters on the southern limit of the Japan current, and those on the northern limit of the great equatorial stream. Along the N. W. coast of America, S. of Sitka, we meet with a cold current running S., and following the inflections of the land, with a mean breadth of 800 m. On the coast of Lower California the W. direction begins to be very marked; and at Cape San Lucas its course is W. S. W., when it is absorbed in the great equatorial current of the North Pacific. The temperature at Monterey is as low as 56°, but at Cape San Lucas it has reached 73°. This brings us back nearly to our starting point in the northern hemisphere. In order to complete our general study of the Pacific ocean, we must mention the periodical current of the W. coast of Mexico, which, occasioned by the monsoons of this coast, resembles them in its alternations. It extends from Cape Corrientes to the Cocos islands, preserving a nearly uniform breadth of 850 m. It was first noticed by Humboldt, and subsequently confirmed by Basil Hall and Beechey. The following table, taken from Kerhallet, exhibits the mean velocity of the currents of the Pacific ocean in 24 hours:

SOUTH PACIFIC OCEAN.

Southern equatorial current.....	24 miles.
Cross current.....	30 "
Current of Cape Horn.....	18 "
Humboldt's current.....	15 "
Current of Mentor.....	16 "
General current of Australia.....	13 "
Periodical currents of Australia.....	6 miles near the land. 16 miles at sea.

NORTH PACIFIC OCEAN.

Northern equatorial current	80 miles.
Equatorial counter current	15 "
Monsoon current of the Carolines	8 "
Japan current	81 "
Current of N. W. coast of America	16 "
Current of Kamtschatka	8 "
Behring's current	14 "

—Any one who has followed us in our description of the winds and currents, will readily understand how essential an accurate knowledge of them is, how much a voyage may be protracted or endangered through ignorance of them, and how frequently, by turning them to the best account, the navigator may exemplify in his own case the common saying, that the longest way round is sometimes the shortest way home. In general the navigation of the Pacific on its principal routes of commerce and transit has been rendered safe, convenient, and expeditious, by the zeal and ability of that long line of illustrious navigators who have identified their names with the physical history of this part of the globe. We annex a list of the most distinguished explorers and discoverers in this region: Frézier, 1713; Anson, 1740-'44; Bougainville, 1768; Cook, 1768-'79; Surville, 1769; Marion, 1772; La Pérouse, 1785; Mears, 1788; Marchand, 1791; D'Entrecasteaux, 1793; Butler, 1794; Carteret, Hunter, Vancouver, 1790-'95; Broughton, 1795; Hogan, 1796; Fearn, 1798; Baudin, 1800; Krusenstern, 1804; Golownin, 1811; Kotzebue, 1813; Freycinet, 1817; Duperrey, 1822; Bougainville, 1824; Lütke, 1825; Beechey, 1825; Dumont d'Urville, 1826; Downs and Reynolds, 1831; Vaillant, 1836; Du Petit-Thouars, 1837; Dumont d'Urville, 1837; Wilkes, 1838-'42.—See Romme, *Tableau des vents, des marées et des courants qui ont été observés sur toutes les mers du globe* (2 vols. 8vo., Paris, 1817); Krusenstern, *Recueil de mémoires hydrographiques pour servir d'analyse et d'explication à l'Atlas de l'Océan Pacifique* (St. Petersburg, 1824); Berghaus, *Physikalischer Atlas* (2 vols. Gotha, 1849-'52); Kerhallet, *Considérations générales sur l'Océan Pacifique* (Paris, 1856); Alexander Keith Johnston, "Physical Atlas of Natural Phenomena" (new and enlarged edition, 1856); Fitzroy, "Narrative of the Surveying Voyages of His Majesty's Ships Adventure and Beagle, 1826, 1836" (London, 1839).

PACIFIC RAILROAD, a projected road to connect the Mississippi river with the Pacific ocean. It was first brought into public notice by Mr. Asa Whitney, who from 1846 to 1850 agitated the scheme in addresses to state legislatures and to popular meetings. He proposed to construct the road by the sale of the public lands along its line, and he asked from congress a free grant of alternate sections for a width of 80 miles on each side to be given to himself and his heirs and assigns for the purpose. His design was to commence at Prairie du Chien on the Mississippi, cross the Rocky mountains at the South pass, and fix the principal Pacific terminus on Vancouver's sound, with a branch from some convenient point west of the

mountains to San Francisco. One of the great objects which Mr. Whitney proposed to accomplish by the enterprise was to render America the route of Asiatic commerce. The settlement of California, however, furnished a new reason for the building of the road, and the scheme was taken up by the government. Mr. Benton of Missouri for a long period advocated it zealously in the senate and before the people. The explorations of Capt. Fremont, by throwing light upon the physical geography of this great and nearly unexplored region, advanced the project. Finally, in March, 1853, congress made an appropriation of \$150,000 to defray the expenses of the necessary surveys, and in that year six parties were organized and sent out by the war department. These parties were fitted out in the most complete manner, with a view to collect all possible information relative to the great physical characteristics of the region traversed, including its topography, its elevation above the sea, its climate, its geology, its botany and its natural history, as well as all details bearing upon the actual construction of the road. Excepting the more northern, the explorations were all in charge of officers of the corps of topographical engineers, U. S. A. The first expedition was led by Gov. Isaac I. Stevens, formerly of the army, on the line of the 47th and 49th parallels of N. latitude. It consisted of four separate parties. One, under Gov. Stevens's personal supervision, penetrated from St. Paul westward toward the mouth of White Earth river; thence by the prairies lying along the Missouri river to the Rocky mountains; and then among the passes of that region. Another, under Capt. McClellan, U. S. A., began at Fort Vancouver on the Columbia, explored to the north-eastward, examining the passes of the Cascade range, and then eastward to join Gov. Stevens. Another party, under Lieut. Donelson, U. S. A., examined the Missouri from its mouth to the Yellowstone, where a junction was made with that under Gov. Stevens. The fourth party, under Lieut. Saxton, U. S. A., conducted a reconnoissance from Fort Walla-Walla to the Bitter Root valley. The second expedition was on the line of the 38th and 39th parallels, and was commanded by Capt. Gunnison, U. S. A. It started from Westport, Mo., and followed the valleys of the Kansas and Arkansas rivers to the Rocky mountains. After carefully exploring the savage region between the Sangre del Cristo pass and Sevier lake, a portion of the party, including Capt. Gunnison, was massacred by Indians. The command devolved upon Lieut. Beckwith, who proceeded to Salt Lake City, where he received instructions to extend the exploration westward upon the line of the 41st parallel. This he did in the following spring, crossing the Sierra Nevada near Fort Reading, and thence following the valley of the Sacramento to San Francisco. The 3d expedition, commanded by Capt. Whipple, U. S. A., was on the line of the

35th parallel. It started from Fort Smith, and took the route by the valley of the Canadian river and Anton Chico to Albuquerque. Thence it proceeded westward by Zuni, the valley of the Colorado Chiquito, the valley of Bill William's fork, the valley of the Mohave, and the Cajon pass, to San Pedro on the Pacific. The 4th expedition, under Lieut. Williamson, U. S. A., was fitted out at San Francisco, and passing up the San Joaquin and Tulare valley explored the region about Walker's, the Tejon, and other passes, and portions of the Mohave and Colorado rivers. The 5th expedition was over the western half of the line of the 32d parallel, and was commanded by Lieut. Parke, U. S. A., who was detached from Lieut. Williamson's party for the purpose. It proceeded by way of Warner's ranch to Fort Yuma, and up the Gila to the Pimo and Maricopa villages, thence by way of Tucson and Doña Ana to El Paso. The 6th expedition was on the eastern half of the line of the 32d parallel, and was commanded by Capt. Pope, U. S. A. It started from El Paso, and proceeded in almost a straight line eastward to Preston on Red river, passing through the Guadalupe mountains, crossing the Pecos at the mouth of Delaware creek, and traversing the Llano Estacado for a distance of 125 miles.—In 1854 congress made two more appropriations of \$40,000 and \$150,000 respectively for deficiencies and for continuing the work.

Three additional parties were organized. The first, under Lieut. Parke, U. S. A., examined certain new lines near the 32d parallel suggested by his former exploration, and surveyed a new connection with San Francisco by way of Los Angeles and the Salinas river. The second, under Lieuts. Williamson and Abbot, U. S. A., explored the Sierra Nevada and the Cascade mountains between San Francisco and the Columbia river, with a view to determining the practicability of connecting any northern road with the former city. The third, under Capt. Pope, made some experiments in Artesian well boring on the Llano Estacado, the object being to determine the feasibility of obtaining by this means a supply of water for a railroad or other purposes. The reports of these surveys have been presented in 13 vols. 4to., and printed by congress, with handsome illustrations and elaborate maps and profiles. For exact information relative to the physical characteristics of the great West, they will long remain the standard authority. The determination of the relative practicability of the several routes for a railroad was intrusted by the Hon. Jefferson Davis, then secretary of war, to Capt. Humphreys, U. S. A., who made an elaborate report contained partly in vol. i. and partly in vol. vii. of the series. His final conclusions are presented in the following abridged table from vol. vii.:

Routes.	Distance by air line.	Distance by proposed railroad route.	Sum of ascents and descents.	Length of level route of equal working expense.	Comparative cost of different routes.	No. of miles of route through arable land.	No. of miles of route through land generally unsuitable, arable soil being found in small areas.	Altitude above the sea of the highest point on the route.	Remarks.
	Miles.	Miles.	Feet.	Miles.				Feet.	
Route near 47th and 49th parallels, from St. Paul to Seattle.....	1,410	2,025	19,654	2,378	\$140,871,000	585	1,460	6,044	Tunnel at elevation of 5,219 feet.

Bills to authorize the construction of a road upon several of these routes have at different times been before congress, the last of which proposed three roads, one from Lake Superior

to Puget's sound, the second from the western borders of Missouri and Iowa through Utah to San Francisco, and the third from the western border of Texas, also to San Francisco.

PACINI, GIOVANNI, an Italian composer, born in Syracuse in 1796. He was sent at an early age to Rome to be educated as a chapel-master, whence he is known in Italy as Pacini di Roma. His tastes led him to cultivate secular music, and at the age of 18 he produced a comic opera entitled *Annetta e Lucinda*, which proved successful. From that period until 1830 he was a prolific composer of pieces for the stage, which in style resemble the productions of Rossini. In 1831 his opera *Giovanna d'Arco* failed in Milan, although sung by Rubini, Tamburini, and Mme. Lalonde; and the composer, disgusted with his ill success, ceased thenceforth to write for the stage. One of his best known operas is *Saffo*.

PACTOLUS (now *Sarabat*), a small river of Lydia which had its source in the N. side of Mt. Tmolus, and, after a northerly course past Sardis, united with the river Hermus. When Midas besought Bacchus to take back from him the fatal gift of turning all that he touched to gold, the god directed him to bathe in the Pactolus, whose sands thereupon were converted into the precious metal. (See *MIDAS*.) The river was long famous for its gold washings, but at the beginning of the Christian era the "golden sands" were not worth collecting.

PAOUVIUS, MARCUS, a Roman dramatic poet, born in Brundisium about 219 B. C., died there in 130 B. C. He is said to have been a nephew of Ennius, and was a friend of Lælius and Accius. He passed most of his life in Rome, where he devoted himself with considerable success to painting, and executed some works in the temple of Hercules in the forum Boarium. The ancient writers agree in styling him one of the greatest of the Latin tragic poets; and though most of his subjects were borrowed from the Greek dramatists, his plays were not mere translations like those of his predecessors, and his style was elevated and forcible. He composed several tragedies founded on Roman history, in one of which, entitled *Paulus*, the hero was Lucius Æmilius Paulus, the conqueror of Perseus, king of Macedon. He was also the author of a play called *Orestes*. Only fragments of his writings are now extant. They were collected by Henry Stephens (Paris, 1564), and have since been printed by Bothe in his "Fragments of the Latin Scenic Poets" (Leipsic, 1834), and in several editions of the *Corpus Poetarum Latinorum*.

PADANG. See *SUMATRA*.

PADERBORN, a town of Prussia, capital of a circle of the same name in the government of Minden, Westphalia, situated on the river Pader and on the railway from Berlin to the Rhine, 41 m. S. from Minden; pop. 10,768. It has narrow, tortuous, and gloomy streets, and contains a cathedral of the 14th century, a seminary with faculties of theology and philosophy, a Catholic gymnasium, a normal school, 4 convents, and blind, lying-in, and orphan asylums. It is the seat of the Westphalian historical and antiquarian society, has manufac-

tures of brandy and several other articles, and carries on a considerable trade in agricultural produce. Paderborn was founded by Charlemagne, who assembled here several diets of Saxony, and made the town a bishopric, which was subsequently erected into a principality of the empire. In the middle ages it belonged to the Hanseatic league. Ceded to Prussia in 1803, it was incorporated with the kingdom of Westphalia in 1806, and restored to Prussia by the treaty of Vienna.

PADILLA, JUAN LOPEZ DE, a Spanish patriot, born about 1490, executed at Villalar, April 24, 1521. He was the son of Don Pedro Lopez, a nobleman who held the office of *adelantado mayor* of Castile. Gifted with talents, courage, and high spirit, he was one of the foremost to complain of the grievances to which the Spaniards were subjected under the Flemish officials appointed by Charles V.; and when the cortes in 1520 voted the monarch a "free gift" without obtaining the redress of any of their wrongs, he incited the people of Toledo to rise in insurrection. Being appointed their leader, he seized the gates, forced the governor to surrender the castle, and organized a popular form of government composed of deputies from each parish of the city. Similar risings took place at Segovia, Toro, Salamanca, Murcia, and Avila; and at a meeting in the last named city a solemn league was formed by the revolutionary party, and the care of their interests committed to a *junta de las comunidades* composed of deputies from all the towns. The cardinal Adrian of Utrecht, who held the regency of Spain, ordered Ronquillo, one of the king's judges, to repair to Segovia with a body of troops and proceed against the insurgents according to law; but the inhabitants shut their gates against him, and before he could force an entrance Padilla, arriving with reinforcements from Toledo, obliged him to retire with the loss of his baggage and military chest. In a short time the rebellion was almost general. Padilla marched suddenly to Tordesillas, where the queen mother Joanna resided, and, renouncing the authority of the regent, placed her at the head of the government. The queen, who had long been in a state of mental debility, seemed for a brief interval to recover her reason, and her speedy relapse into her former condition was carefully concealed. The junta now removed to Tordesillas, and sent Padilla to Valladolid to seize the members of the council and bring away the public archives, seals, and treasury books. The cardinal regent was deposed, and a remonstrance was despatched to Charles, in which the junta proposed a thorough reform of the political constitution of the state. The nobility, who saw in these measures an attack upon the privileges of their order, were filled with indignation, and, when an army of 20,000 men was soon afterward raised, succeeded in depriving Padilla of the command and conferring it upon a young noble named Don Pedro de Giron, whose incapacity

led to the capture of Tordesillas by the royalists, the seizure of the queen's person, and the recovery of the public seal. The quarrel between the nobles and the commons now broke through all restraint. Giron retired to his estate. The army of the people rapidly augmented, and Padilla again taking the command made himself master of several small towns, and advanced upon Torrelobaton, which he carried by storm after a desperate siege. The fruits of this victory were lost however by the irresolution of the junta, which consented to a short truce during which the undisciplined popular army rapidly dwindled away, while the royalists under the conde de Haro had time to prepare for battle. As soon as the truce expired Haro advanced upon Torrelobaton, and Padilla retreated. He was overtaken at Villalar, April 23, 1521, defeated, and made prisoner, and on the next day was executed with his two principal officers without any form of trial.—MARIA PAOHECO, the wife of the preceding, belonged to one of the most illustrious families of Spain, and was an ardent supporter of her husband. When he was in great strait for money after the defeat of Giron, she proposed to seize the rich ornaments in the cathedral of Toledo, and to avoid the appearance of sacrilege entered the church with her retinue clad in mourning, and falling on her knees, beating her breast, and asking pardon of the saints for what she was about to do in a good cause, stripped the shrines and altars of all that was valuable. After her husband's death she placed herself at the head of the popular party, invited the French, who had just invaded Navarre, to advance into Castile, and neglected no means to keep alive the revolutionary spirit. The French however were defeated, the insurrection was gradually subdued, and Toledo at last falling after a long siege, she escaped into Portugal, where she passed the rest of her life.

PADILLA, LORENZO DE, a Spanish historian, born in Antequera, Andalusia, died in 1540. He was archdeacon of Ronda, and one of the historiographers of Charles V., and left a general history of Spain, only a small part of which was ever printed. He was also the author of a *Catalogo de los santos de España* (fol., Toledo, 1598), and a *Libro de las antigüedades de España*, edited by Pellicer (12mo., Valencia, 1669). Other works by him are yet unpublished.

PADISHAH, a title assumed by the Turkish sultan. It is a Persian word derived from *pad*, protector or throne, and *shah*, king or prince. Originally the Ottoman Porte gave this title to the king of France only, the other European monarchs being called *kral*; but it is now also applied to the emperors of Russia and Austria.

PADUA (It. *Padova*), a province of Austrian Italy, bounded N. by Vicenza and Treviso, E. by Venice, S. by Polesina, S. W. by Verona, and N. W. by Vicenza; area, 836 sq. m.; pop. in 1857, 818,000. In the W. is a volcanic group called the Euganean hills, near which are nu-

merous mineral springs. The surface in other parts is generally level. The principal rivers are the Adige, which forms the S. boundary, the Brenta, the Musone, and the Bacchiglione. The soil is fertile, and wheat, maize, rice, hemp, flax, grass, and the grape are carefully cultivated. Sheep, poultry, silk, and oil are also produced. The province is traversed by a number of irrigating and navigable canals.—PADUA (anc. *Patavium*), the capital of the above described province, is situated on the Bacchiglione, 20 m. W. from Venice, in lat. 45° 24' N., long. 11° 52' E.; pop. about 50,000. It is connected by railway with Venice, and is traversed by several canals, which give it communication with the lagoons and other places. The Italians sometimes call it *Padova la Forte*, and in ancient times it certainly deserved that appellation, but its defences are now dilapidated. The old wall which surrounds it is triangular in form, bastioned, pierced by 7 gates, and faced by a dry ditch of no great depth, which can readily be filled with water. It is about 6 m. in circuit. The city is irregularly built, and in its general aspect gloomy and unattractive. The narrow, unpaved, and dirty streets are lined by arcades or long rows of arches, generally pointed, supporting the houses, and are interrupted here and there by irregular open spaces, and on the outskirts by wide *piazze*. The houses are old, lofty, and for the most part well built, and many of the public edifices are fine specimens of architecture. The *palazzo della ragione*, or town hall, built between 1172 and 1219, stands entirely upon open arches surrounded by a loggia, and is covered by a vast roof unsupported by pillars and rising about half as high again as the walls. The great hall is 240 feet long, 80 feet wide, and 80 feet high. It is closely covered with curious allegorical paintings in 819 compartments, said to have been designed by Giotto, but entirely repainted after having been several times damaged by fire and water. The hall is also decorated with two Egyptian statues presented by Belzoni, a bust of the traveller himself, a bust of Lucrezia Dondi, and a bust with the inscription P. T. L. E., which Paduan antiquaries interpret to mean *Patavini Tito Livio Erexerunt*, "Erected by the Paduans to Titus Livy." The *duomo* or cathedral is said to have been designed by Michel Angelo, but it was not completed until 1754, having been two centuries building. It is of brick and not remarkable for its architecture, but has some good paintings. The baptistery, a Lombard building of the 12th century, contains many interesting frescoes. The *biblioteca capitolare*, or cathedral library, owes its foundation partly to Petrarch, who was a canon of Padua, and whose portrait, cut from the wall of the house in which he lived, is now in the library building. The bishop's palace and the *palazzo del capitano* are also worthy of notice. The central part of the latter is occupied by a remarkably fine clock tower. The church of

Sant' Antonio and the *scuola de Sant' Antonio* adjoining it contain some fine paintings. The church of Sta. Giustina is a fine marble edifice, also rich in works of art. In front of it is the Prato della Valle, an oval surrounded by a small canal and decorated with about 80 statues, 2 of which are by Canova. In the midst of the Arena, the ruins of a Roman amphitheatre afterward converted into a fortress, is a chapel built by Giotto and adorned with some of his best paintings. The university of Padua, founded early in the 13th century, was a famous school of law and medicine, and is still the most celebrated seat of the latter science in Italy. It has also faculties of theology, law, and humanities, and from 1,500 to 2,000 students. The present edifice was begun in 1493, and the interior cortile, by Palladio, has great beauty. Galileo taught mathematics here for 20 years, and a stolen bit of his spine is preserved in the museum. It was at this university, according to common belief, that dissection of the human body was first practised for scientific purposes. The botanic garden of Padua, established in 1543, is the oldest in Europe. The city has a celebrated society of arts and sciences, an episcopal seminary, several inferior institutions of learning, and various libraries and museums. It manufactures silks, ribbons, leather, and woollen cloth, and trades in wine, oil, cattle, and garden vegetables. The fair of St. Anthony, which lasts during 15 days in June, is an occasion of great bustle and gayety.—Padua is one of the most ancient cities of Italy, and according to the legend, of which Virgil makes mention in the *Aeneid*, was founded by Antenor after the fall of Troy. In 1274 a skeleton enclosed in a marble sarcophagus and grasping a sword was dug up in Padua, and at once pronounced to be that of the Trojan founder. The sword was given to Alberto della Scala in 1384, and the sarcophagus now rests under a *baldachino* in one of the streets. The ancient Patavium was the capital of the Veneti, and became a rich and powerful city. Even after it fell under the power of the Romans it continued for some time to be one of the first cities of upper Italy, but it was gradually surpassed by Aquileia and Mediolanum. Destroyed by Attila in 452 and by the Lombards in 601, it rose each time from its ashes, and by the 10th century had become once more one of the most important places of northern Italy. In 1289 it became subject to the great Ghibelline leader Ezzelino da Romano, surnamed from his cruelty the Feroctions, who, after 50,000 persons had perished through his means, was defeated in 1259 by a league of several cities, and died in prison. Padua was now for some years independent, but in 1387 passed into the hands of the house of Carrara, and in 1405 into those of Venice, with which it was transferred to Austria by the treaty of Campo Formio in 1797. Among the distinguished natives of Padua are Livy, Thrasea Pæstus, and Belzoni.

PADUCAH, the capital of Macracken co., Ky., on the left bank of the Ohio river, immediately below the mouth of the Tennessee, 847 m. by the river below Louisville; pop. in 1860, 7,000. It has an active trade, receiving large quantities of produce by the Tennessee and Cumberland rivers and the New Orleans and Ohio railroad. It contains several manufacturing, the county buildings, 3 ship yards, 2 tanneries, 8 steam saw mills, 3 banks, and 10 churches.

PÆAN (Gr. Παιων, Παιωνος, or Παιωνος), according to Homer, the physician of Olympus; afterward a surname of *Æsculapius* the god of healing, and still later one of the names of Apollo. In the sense of "deliverer," the word was also applied to Thanatos or Death. From Apollo it was transferred to a triumphal song dedicated to him, and generally sung before or during a battle, and after a victory. The pæan before battle however was, according to some writers, a hymn to Mars. The pæan was always a loud and joyous song, and if chanted by way of supplication expressed hope and confidence. The burden of the choral chants was *Ω* or *ω* Παιων. Pæans were occasionally sung to other gods, and even to mortals. The Lacedæmonians sang one to Neptune, the Greek army under Xenophon to Jupiter, Aratus to the Macedonian Antigonus, the Delphians to the Macedonian Craterus, and the Rhodians to Ptolemy I.

PÆONY, the familiar name of a number of species of highly ornamental garden plants, belonging to the natural order *ranunculacea*, and blossoming through several weeks in the early part of the floral season of the year. The word pæony seems to be derived from *paonia*, said to have been applied to the plants by Hippocrates and Dioscorides in honor of Pæon the physician, who first made use of them in medicine; but Don thinks that it more probably was derived from Pæonia, a mountainous country of Macedonia, where some of the species grew. The pæonies are divided into two groups, those which are herbaceous and those which are shrubby; but the woody stems of the latter are of a herbaceous character, with very large pith. The roots of the pæonies are either tuberous or ramose; the foliage consists of biternate or bipinnate leaves; the flowers are large, rosy, crimson, or white; calyx with 5 leafy, unequal, permanent sepals; petals 5 to 10, somewhat orbicular; stamens numerous and polyandrous; disk fleshy; stigmas thick, bilamellate, surmounting the large, many-seeded, 2 to 5 follicular carpels; seeds large, black, and affixed by thickened crimson threads to the suture. The garden sorts are mostly those of double and multiplex petalled varieties, but there are many single-flowered or original forms worthy of cultivation. Some of these, as well as of the double sorts, we shall briefly enumerate.—The first species introduced into England was the officinal (*paonia officinalis*, Linn.), a native of Switzerland and of other parts of Europe; it was known in cultivation

as early as 1548. This species has large, single, crimson flowers, with yellow stamens, stems about 2 feet high, branches spreading. Its flowers appear from the 1st to the 6th of June. In this its primitive condition it is deemed worthy of cultivation. Of its numerous varieties, the bluish (*P. o.*, var. *blanda*) is considered to be not a very desirable plant in the garden; it has the same habit as its parent; its flowers are only middle-sized, of a pale purple, and appear about the 1st of June. The whitish flowered (*P. o.*, var. *albicans*) is, on the other hand, one of the best, with fine, large, double flowers of a pale rosy color when they first expand, but gradually changing to nearly white; it is a free flowerer and desirable. The flesh-colored (*P. o.*, var. *carneascens*) is a very showy double variety, with pale rosy flowers faintly striped with a deeper tint; its flowers appear later than the others. Sabine's pæony (*P. o.*, var. *Sabini*), though a single kind, is very showy, with its extremely large, brilliant flowers, and bright yellow stamens. The old double red pæony (*P. o.*, var. *rubra*) is one of the showiest and most desirable, and has accordingly become so general, that seldom is there a garden of any pretensions that is without it; its rich dark crimson and abundant petals seem to entitle it to a better descriptive name than *rubra* (red), and in some flower catalogues it is designated as the *atrorubens*, a synonyme which may however cause confusion unless known. A second species is the edible pæony (*P. albiflora*, Pallas), a native of Siberia, and first introduced into England in 1784. It has large single white flowers, with bright yellow stamens; it grows about 8 feet high, branches much near the top, has a smooth, shining foliage, and blossoms about the middle of June. The best varieties with single flowers produced from it are the Tartarian (*P. a.*, var. *Tatarica*), a tall and erect plant, with flowers in great numbers, often in clusters from 2 to 6 on a branch, of a pale pink or flesh color. Another with flesh-colored petals (*P. a.*, var. *canadida*) is a like tardy blooming sort. Of the double are several introduced from China and very desirable in every garden, comprising the double white (*P. a.*, var. *Whitleyi*), whose flowers are produced on tall erect stems, the outer petals large and rounded, the inner narrower and more erect, of a creamy yellow at base—in perfection toward the end of June; the double crimson (*P. a.*, var. *Humei*), equally elegant, with very large double rose-colored blossoms; the rose-scented (*P. a.*, var. *fragrans*), with erect stems, large, double, deep rose-colored flowers, blossoming usually toward the end of June, with an odor when slightly perceived not unlike the perfume of the hardier kinds of roses; the *P. a.*, var. *Potzii*, introduced from China in 1822, with splendid crimson flowers, and of the same habit as the others; and the *P. a.*, var. *Reeverii*, of great magnificence, with large pale rose flowers, the petals having a velvety appearance. The freedom

with which the edible pæony in some of its varieties can be impregnated, sometimes naturally, at other times by art, has enabled amateurs to raise still other superb or beautiful varieties, so that they have supplanted the earlier kinds, and surpassed them often in contour, color, and size of the flowers. In form some have flowers like the double anemone, and are called anemone-flowered on that account; thus the *anemoniflora striata* is described with outer petals very large, rosy violet, centre ones small rose and salmon, those in the middle elevated, forming a compact tuft at the centre. Another style is that with full and globular flowers, the stigmas obliterated, and known as the *Humea alba*, a remarkable variety. The *Victor modeste*, a French seedling, has large, full flowers, whose outer petals are of a beautiful rosy violet, those of the centre having each a large salmon-colored line running through them. A generally admired species, of a dwarfish habit with singularly beautiful fine-cut foliage, sometimes called the parsley-leaved pæony, is the *P. tenuifolia* of Willdenow, a native of Siberia; its blossoms are of a rich bright crimson; from this originated a double variety, with splendid double red flowers. One of the handsomest of the single pæonies is the *P. paradoxiaca* (Andrews), a native of the Levant, with wavy, glaucous foliage, and flowers whose large purple petals contrast finely with the yellow stamens; the fringed pæony (*P. p.*, var. *fimbriata*) is a double variety of it, ranking in beauty with the very choicest garden kinds. The number of distinct species of the herbaceous pæonies, according to Persoon, is 7. De Candolle enumerates more than twice as many, but probably several are no more than varieties of a few prominent forms.—The tree pæony (*P. moutan*, Sims) and its varieties are among the most remarkable plants of which the flower garden can boast. The word *moutan* has been applied to this species of pæony in China for more than 1,400 years; it also bears a name in that country which signifies the "king of flowers," alluding to the magnificence of the plant. Several of its varieties command the most extravagant prices there. The tree pæony is found in China and Japan, in a wild state in the north of China, and on the mountains in the province of Ho-nan. It was first observed by Europeans in the gardens at Canton, introduced into England by the exertions of Sir Joseph Banks, and received at the royal garden at Kew in 1787. From England it passed over to France and other parts of Europe in 1803, but when first seen in American gardens is unknown. In sheltered situations the plant will attain to a height of 6 to 10 feet in a few years, and no shrub can be more gorgeous, abounding as it does in leaves deeply cut into many-branched segments, and in very magnificent flowers of extraordinary size, which appear early in spring. One of the most showy varieties is the poppy-flowered tree pæony (*P. m.*, var. *papaveracea*, Andrews), which has in-

deed been adopted by some botanists as the type of the species. Its flowers are nearly single, consisting of 8 or 13 petals, white, with a deep purple spot on the lower part or base of each; the spots are rayed in lines about an inch and a half long from the centre, forming a star in the middle of the flower. Preceding the cultivation of this, however, was the Banks's moutan pæony alluded to above, and which is the sort most commonly seen in our gardens, having very large, full, and spreading blossoms, measuring in expansion 4 to 8 inches in diameter. The number of the petals depends upon the strength and health of the plant; variations in the size of the flowers take place in the same season and on the same plant, the older plants producing the finest blooms. The color is a light pink, becoming nearly white at the edges of the petals; there is also a purplish red spot at their base. The out-petalled tree pæony (*P. m.*, var. *lucera*) is a very beautiful variety, and strikingly different from the others in the bright, rosy red of the petals, the innermost of which are much cut and gashed, curled up and distinctly bordered with a narrow edge of light carmine, which gives the whole flower a peculiarly rich and finished appearance. Twelve distinct varieties of the tree pæony are given by Mr. London in his *Arboretum Britannicum*, and mention is made of others said to be in the possession of the Chinese, but the colors of the flowers of which render their existence dubious.—The only species as yet known native of America is the *P. Brownii* of Douglass, with an herbaceous, striate stem, leaves smooth on both sides, ternate or biternate, leaflets pinnatifid, lacinate; lacinae oblong, those of the lower leaves obtuse; flowers small; sepals unequal, oval; petals of a reddish purple color. It is found near the confines of perpetual snow on the subalpine range of Mt. Hood, N. W. America; in Oregon, and on the Sierra Nevada of California. Dr. Torrey considers the *P. Californica* of Nuttall as identical.—The pæony is readily propagated by division of the roots and by seeds; and when these are procured by cross impregnation of choicer kinds, the chance of raising novelties of much value is greatly increased. Superb varieties have been accordingly raised in the different portions of the United States, particularly by amateurs in the vicinity of Boston. In selecting the seeds for sowing, the smaller ones in the capsules are the best as most likely to produce the most full-petalled flowers. In like manner the tree pæony has been reared from seed with encouraging success. The seedling plants come into blossom in 3 to 8 years, according to the care bestowed upon them. The tree pæony is also propagated from suckers which spring from the root, by layers, cuttings, and by grafting. September is considered the best time to remove the suckers, which should be skillfully detached from the main plant by a sharp knife, securing a portion of the roots. Layering is performed

in the spring when the buds begin to swell, fastening the outer shoots into the soil by a wooden peg or hook, and slitting the lower side of the layer, an operation which requires much care on account of the brittleness of the wood; a modification of this plan is by girdling or ringing, *i. e.*, removing a ring of bark just below the buds at the shoots intended to be rooted in the process of layering. Cuttings should be taken off in August or September with a portion of the old wood attached, and planted in pots in a compost of loam, leaf mould and a large proportion of sand, covered with a bell glass, kept shaded and protected in winter from frosts, and toward spring plunged into a hot-bed to start the roots. Grafting is seldom resorted to, unless to increase some rarer variety, and the method is that termed crown grafting. The several sorts may be cultivated in the open air, covering the plants in winter in colder latitudes, and where deep snows might break the branches, with a perforated barrel, cask, or box, a method that secures the flowering for the next season, which sometimes fails. In pot culture the chief care is in not allowing the plants to start suddenly into growth and push their flower buds immaturity. If kept in a shady part of the greenhouse or conservatory, the display of blossoms will be longer preserved. The soil fitted for them is mostly good loam with a little leaf mould; and in the border a good loamy soil, with occasional prunings of the plants, will be found the best mode of cultivation.—The chief importance of these plants consists in the beauty of their flowers, which add so much to the character of a garden. The roots of *P. albiflora* and of *P. anomala*, according to Pallas, are eaten in Siberia, either simply boiled or as an ingredient in soups; and the seeds of the former are used in the same country instead of tea. Pæony seeds are however emetic and cathartic; and the root has the credit of being antispasmodic. All the species have an acrid principle concentrated in their roots and seeds, and they were formerly in great repute in medicine. The fresh roots of *P. officinalis* are acrid-narcotic, but when dry they are almost inert; and the dried petals, which are slightly astringent, are still occasionally preserved for use.

PAER, FERDINANDO, an Italian composer, born in Parma in 1774, died in Paris, May 3, 1839. He exhibited much musical precocity, and is said to have composed an opera at the age of 10. Being placed in independent circumstances through the liberality of his godfather the grand duke of Parma, he was enabled to acquire a thorough education in music and in the various branches of polite learning. After producing several operas at Vienna and acting as chapelmaster at Dresden, he was in 1806 taken into the service of the emperor Napoleon, who appointed him imperial composer. He enjoyed equal marks of favor from the Bourbons, and between 1818 and 1825 was director of the Italian opera in Paris. He was a prolific

composer of operas, cantatas, overtures, &c., and his dramatic pieces abound in striking melodies, with effective accompaniments. His chief operas are *Camilla*, *Sargino*, *Achille*, *Leonora*, *Dido*, *Griselda*, and *Agnes*.

PÆSTUM (originally *Posidonia*, city of Poseidon or Neptune), an ancient city of Lucania in southern Italy, situated in the N. W. extremity of that province, about 4 m. S. E. from the mouth of the Silarus (Selo), and upon a bay of the Tyrrhenian sea, called *sinus Pæstanus* (now gulf of Salerno). Its site, in the Neapolitan province of Principato Citra, is now called Pesto, and is covered with magnificent ruins, on a level uninhabited plain by the sea shore. The principal remains are those of two temples, hexastyle peripteral buildings, which, with the exception of the temple of Corinth, are considered to be the severest and most massive examples of Doric architecture now extant. The finer and older of the two, known as the temple of Neptune, is open to the sky, and is 180 feet long and 80 feet wide. The other, variously called the temple of Vesta and of Ceres, is 107 feet in length by 48 in width. There is another edifice supposed to have been a basilica, but whose purpose it is impossible to determine. Beside these buildings, there are the ruins of an amphitheatre, of many private houses, and of the walls and gates. The walls are built of large polyhedric masses of travertine, and form an irregular pentagon 3 m. in circuit; they are in many places still 12 feet high. Remains of 8 towers and 4 gateways are traceable, and the eastern gateway with an arch 50 feet high is almost perfect. Around and amid the whole grow profusely the famous Pæstan roses, which even in their wild state flower twice a year, and are remarkable for their fragrance.—The origin of Pæstum, or rather Posidonia, is doubtful. A colony of Greeks from Sybaris settled there in 524 B. C., but the city probably had a previous existence. Under the Sybarites it flourished and became powerful. It was taken by the Lucanians about 430 B. C., and thenceforth gradually lost the character of a Greek city, and its inhabitants finally ceased to speak the Greek language. During the war with Pyrrhus the Romans founded there a Latin colony, and it subsequently lost all importance. It is mentioned in the 5th century as the seat of a bishopric, and about the 11th century, after the devastation of the Saracens, it fell into complete decay. Its ruin, generally attributed to foreign enemies, is by Strabo assigned to its unhealthy atmosphere. Sulphurous springs in the neighborhood still form stagnant pools, and a stream running under the walls overflows the low grounds and forms a marsh around the city.

PAEZ, JOSÉ ANTONIO, ex-president of Venezuela, born in Araure, province of Varinas, in 1790. The earlier years of his life were spent among the herdsmen of the plains, and at the age of 18 he became overseer of the cattle estates of a wealthy Spaniard. When in 1810

the revolution broke out, Pæz joined the militia of Varinas in the insurgent army, and in the first campaign was raised to the rank of sergeant of cavalry. The insurrection, however, was put down in 1812. In 1813, on the approach of Bolívar to Venezuela, Pæz was offered by the Spanish commander a captain's commission, but, refusing to accept, made his escape by flight, and again joined the patriot forces. During the campaigns of 1813, '14, '15, he did effective service to the revolutionary cause, and was twice taken prisoner, in both cases narrowly escaping execution. On Feb. 16, 1816, he defeated the royalist chieftain, Don Rafael López, in a night battle at Mata de la Miel, on the right bank of the river Apure, and again in June of the same year worsted him at Montecal. The result of the campaign, however, had proved hitherto disastrous to the patriot army. Venezuela, New Granada, and the plains of Casanare were in the hands of the Spaniards. Toward the close of 1816 Pæz was made commander of the revolutionary forces, with the rank of brigadier-general, and immediately setting out against the enemy, defeated the Spanish general López, took the city of Achaguas, and recovered the province of Apure and a part of Varinas in Venezuela, and Casanare in New Granada. On Jan. 28, 1817, he totally routed the Spanish army under La Torre on the plains of Las Mucuritas. During this year also he acknowledged the authority of Bolívar, who had just gained some successes, and henceforth they acted in concert. In 1819 Pæz was raised to the rank of general of division, and during the campaign of that year acted with success against the Spanish general Morillo. New Granada and Venezuela were now united into one republic under the name of Colombia, with a territory embracing 115,000 square leagues. In 1821 the great battle of the war was fought on the field of Carabobo. In this battle Pæz had command of the leading division, which was required to force its way through a narrow defile, the heights surrounding which were covered by the royalist artillery. Nevertheless, he led his troops forward with such impetuosity, that the Spaniards were driven from their position, and the fate of the day was decided. His services in gaining this victory established his military reputation, and were so conspicuous that Bolívar offered on the spot to appoint him general-in-chief of the army. The result of this battle secured the independence of Colombia, and compelled the Spanish commander, La Torre, to shut himself up in Puerto Cabello, the last stronghold of the royalists in Venezuela. In Nov. 1823, Pæz carried by assault the town of Puerto Cabello, and with the fall of this fortress no trace of Spanish authority was left in Colombia. On the formation of the new government, he entered the senate as representative of the department of Venezuela; and during the years of peace which followed the expulsion of the Spaniards, he devoted himself to study, in order to make up for the defects of his early educa-

tion. At the same time he took an active interest in political affairs, being extremely jealous of Bolivar, and acting as one of the leaders of the federative party. Disaffection to the confederacy had existed for a long time in Venezuela, when an executive order requiring a general enlistment of all citizens between the ages of 16 and 50 brought on an explosion. In the execution of this law in the city of Caracas, Paez gave so much offence by his arbitrary conduct, that the house of representatives determined to impeach him before the bar of the senate. Having been informed of this in April, 1826, he refused to obey the summons, and put himself at the head of the military, and of the large party opposed to the constitution. Venezuela was thus in a state of rebellion, and so it remained until the return of Bolivar, who quieted the insurrection, recognizing Paez as the commander in Venezuela. A general amnesty was promised, and also a convention to reform the constitution. The troubles however continued, and in Sept. 1829 Venezuela declared itself independent, and Paez was elected in the following year the first president of the republic, under the new constitution. A military insurrection against the government under the lead of Gen. José T. Monagas soon broke out, but was speedily quelled. After the close of his term of office Paez retired to his estates. A second insurrection by Monagas against the new president, Vargas, called him again into the field; and being a second time successful, he was presented by congress with a golden sword for his services, and honored with the title of "illustrious citizen." In 1839 he was again elected president, was succeeded by Soubllette, and he in 1846 by Monagas, whose election Paez promoted, hoping that thus his ambition would be satisfied. Monagas endeavored to usurp the supreme authority, and on Jan. 24, 1848, attacked the house of representatives with an armed force. A spirit of resistance was aroused, and Paez took the command of the revolutionary forces. He was, however, unsuccessful, was captured and confined in prison in the city of Valencia in 1849, and subsequently in the fortress of San Antonio in the island of Cumana. Finally released by the order of congress that his sentence of exile should be carried into execution, he set sail for the United States on May 24, 1850. There he remained until 1858, and on Dec. 2 of that year he returned to Venezuela, the party of Monagas having been overthrown, and the sentence of banishment against Paez not only having been revoked, but a special invitation to return having been sent to him in New York, where he was residing. In 1860 he was accredited as envoy extraordinary and minister plenipotentiary to the United States, but in 1861 resigned that office in order to return to Venezuela.

PAEZ, PEDRO, a Spanish missionary, born in Olmedo, New Castile, in 1564, died in Abyssinia in May, 1612. He was a member of the

society of Jesus, and in 1587 sailed for Goa, whence he was despatched in the following year with Father Antonio Montserrat to direct a mission in Abyssinia. On the voyage thither they were made prisoners by an Arab pirate and carried to Sana, the capital of Yemen, where they passed 7 years in the most oppressive captivity. Ransomed at length by the viceroy of India, the two missionaries returned to Goa in 1596. Paez, after passing a few years at Diu and Cambay, again took ship for Abyssinia, and in 1603 reached Massowa, where he employed himself for some time in learning the native language, translating into it a compendium of the Christian doctrine, and instructing the children. The king, Za-Denghel, ordered him to appear at court with two of his pupils, and was so much impressed by their proficiency and the missionary's arguments, that he became a convert, and wrote to the pope and to Philip III. of Spain for more missionaries. The Abyssinian priests stirred up an insurrection in which Za-Denghel lost his life (1604); but the next king, Socinos or Melek-Seghed, was still more favorable to the Spaniard, and granted him a piece of ground for a convent, which he built without any other aid than that of the natives. Father Paez accompanied the king on his military expeditions, and on one of these occasions, while making an excursion from the town of Nagnina, discovered the sources of the Abai or Blue Nile, which he was the first European to visit. Bruce endeavors to discredit his narrative, but there is now no doubt of its truth. Paez died of fever, after persuading the king and his principal nobles to embrace Catholicity. After the death of Melek-Seghed the Jesuits were persecuted and the old religion was restored. Nicolas Antonio attributes to Paez a general history of Ethiopia (not published), a treatise *De Abyssinorum Erroribus*, and several letters printed in the *Littera Annua*.

PAGAN, BLAISE FRANÇOIS, comte de, a French military engineer, born in Avignon in 1604, died in Paris in 1665. He entered the French military service at an early age, and at the siege of Montauban in 1621 lost an eye by a musket shot. During the wars which marked the administration of Richelieu, he distinguished himself by his talents and gallantry, and in 1642 attained the rank of *maréchal de camp*. In the same year he had the misfortune to lose his other eye, and being incapacitated for further service in the field, he devoted the remainder of his life to studies connected with his profession. In 1645 appeared his *Traité de fortifications*, which for a number of years was a leading work on military engineering, and which was followed in 1651 by his *Théorèmes géométriques*. He also published a treatise on the planetary theory and some astronomical tables, and translated a Spanish account of the river Amazon, the chart accompanying which he is said to have drawn with his own hand. For an account of his improvements in defensive warfare, see *FORTIFICATION*.

PAGANINI, NICCOLO, an Italian musician and composer, born in Genoa, Feb. 18, 1784, died in Nice, May 27, 1840. He early evinced a remarkable predilection for music, and was subjected by his father to a very severe training. At 6 years of age he was a violinist, and already began to practise novel effects upon his instrument, and to perform feats requiring great power and quickness of execution. At 8 he was so far advanced as to require the best teacher that Genoa could afford, and had composed a sonata of merit, which has been lost; and at the age of 9 he made his first public appearance in the largest theatre in Genoa, rousing the audience to an extraordinary pitch of excitement by the performance of variations, composed by himself, on the French air *La Carmagnole*. In 1797, in company with his father, he made his first musical tour in Italy, and soon after applied himself to composition, producing music which defied the attempts of other violinists, and greatly taxed his own powers. The severe discipline to which his father subjected him meanwhile became so irksome, that before attaining his 15th year he contrived to escape from the paternal authority, and commenced an independent course of concerts at Lucca, Pisa, and other cities. The flatteries and caresses lavished upon him, together with the possession and control of the large sums obtained by his professional labors, had an injurious effect upon the inexperienced boy, who soon fell into habits of dissipation and expended his earnings in debauchery and gambling. For several years he led a vagabond career, and about the age of 18, it is said, formed a connection with an Italian lady of rank, with whom he retired to an estate possessed by her in Tuscany. Here he renounced for a time his favorite instrument and devoted himself to the guitar; but his old tastes returning, he went in 1804 to Genoa and studied composition with renewed vigor. In the succeeding year he commenced another musical tour of Italy, and between 1806 and 1808 held the position of director of the orchestra in the service of the princess Eliza of Lucca, sister of Napoleon. It was at this period that he first performed his remarkable feat of playing the military sonata entitled "Napoleon" on a single string. His restless nature again impelled him to travel, and during the next 20 years he spent his time in the chief cities of Italy, where his fame exceeded that of any previous or contemporary violinist. In 1828 he made his first appearance in Vienna, and was received with an enthusiasm bordering on the wildest extravagance. Poems were composed in his praise, medals struck in his honor, articles of dress were named after him, and the emperor appointed him violinist of his private band. Rumors of having murdered his wife and his mistress were nevertheless circulated against him, which he found no difficulty in refuting. After a triumphant career in Germany he arrived in Paris in March, 1831, and during the next two months produced a sensation almost

without a parallel in that city. Rossini is said to have wept upon hearing him play for the first time. In England, whither he went in May of the same year, his reception was not less enthusiastic, notwithstanding his avarice induced him to charge the most exorbitant prices for admission to his concerts. Soon afterward he retired to a country seat near Parma, but the latter years of his life were rendered unhappy by lawsuits and ill health. He left a fortune of several million francs, the greater part of which was bequeathed to his natural son Achillino, by a Jewess of Milan. His personal appearance, studiously eccentric, his facility in making his instrument produce effects at once startling and unearthly, and a certain mystery connected with his character and early career, gave rise to numerous stories, more or less apocryphal, which greatly enhanced his notoriety. He was of a gross and sensual disposition, in general exceedingly avaricious, and vain to excess of popular applause. As an artist his merit was transcendent, and his name has become a synonyme for all that is excellent in violin playing, notwithstanding that he degraded his art and did injustice to his own powers by feats little better than sleight of hand. His compositions, however, are full of invention and beauty. He excelled in his adagios, which were given with marvellous expression. His life has been written by his friend Schottky under the title of *Paganini's Leben und Treiben* (Prague, 1880).

PAGANISM, a general term applied to all forms of religious worship except Christianity, Judaism, and Mohammedanism. When Constantine forbade the worship of the heathen deities, the followers of the old religion retired to the country villages (*pagi*), where they could practise their rites in secrecy, and were hence called by the Christians *pagani*, or country people. The term thus came in time to denote heathens generally, irrespective of their places of abode. It was in the middle ages ignorantly applied to Mohammedans also.

PAGE. I. A N. E. co. of Va., bordered E. by the Blue ridge and W. by the Massanutten mountains, and intersected by the Shenandoah river; area, about 250 sq. m.; pop. in 1850, 7,600, of whom 957 were slaves. The soil is very fertile. The productions in 1850 were 128,480 bushels of wheat, 187,602 of Indian corn, 2,258 tons of hay, 1,194 lbs. of tobacco, and 12,907 of wool. There were 16 grist mills, 8 saw mills, 5 tanneries, 2 furnaces, 11 churches, and 468 pupils attending public schools. Value of real estate in 1856, \$2,100,422, being an increase since 1850 of 28 per cent. Capital, Luray. II. A S. W. co. of Iowa, bordering on Missouri, drained by the Nodaway and several branches of the Nishnabotona and Takio rivers; area, about 600 sq. m.; pop. in 1859, 3,674. It has a rolling surface and fertile soil. The productions in 1859 were 11,196 bushels of wheat, 2,784 of oats, 285,869 of Indian corn, 10,541 of potatoes, 4,359 lbs. of wool, and 48,712 of butter. Capital, Page Court House.

PAGE, JOHN, an American statesman, born at Rosewell, Gloucester co., Va., April 17, 1743, died Oct. 11, 1808. He was educated at William and Mary college, where he contracted a lasting friendship with Thomas Jefferson, then a student there, and subsequently became a visitor of the college and its representative in the house of burgesses. He was also a member of the colonial council. During the revolutionary struggle he rendered important service as a member of the committee of public safety and as lieutenant-governor of the commonwealth, and he also contributed freely from his private fortune to the public cause. At one time he held command of a militia regiment raised to repel a British invasion. Upon the adoption of the federal constitution he was elected a member of congress, and he continued to act in that capacity during the entire administration of Gen. Washington. In 1802 he was elected governor of Virginia, and soon after the expiration of his term of office was appointed by President Jefferson commissioner of loans for the same state, a position which he held until his death. He left a fragment of a brief autobiography, and also ample materials for a memoir of his life and times, the latter of which have been accidentally lost.

PAGE, THOMAS JEFFERSON, a commander in the U. S. navy, born in Virginia about 1815. He entered the navy as a midshipman in Oct. 1827, was promoted to the rank of lieutenant in June, 1833, and to his present rank in Sept. 1855. In the early part of his service he was employed for a time upon the coast survey. In 1853 he was appointed to the command of an expedition for the exploration of the tributaries of the river La Plata and adjacent countries, from which he returned in May, 1856, after an absence of 3 years and 4 months. His narrative of this expedition was published in 1859 (8vo., New York). In 1857 congress made a further appropriation to complete the exploration of the Parana and tributaries of the Paraguay river. Commander Page was assigned to this service, which was finished in Dec. 1860.

PAGE, WILLIAM, an American painter, born in Albany, N. Y., Jan. 23, 1811. He went to the city of New York with his parents in 1819, and was sent to school to Joseph Hoxie, since become eminent as a politician, who then had a school in the Bowery. He was subsequently sent to a public school, and at the age of 11 received a premium from the American institute for a drawing in India ink. At the age of 14 he was taken from school and put into the office of Frederic De Peyster, with a view to his becoming a lawyer; but Mr. De Peyster, discovering that his pupil had a much stronger propensity for drawing the human figure than legal instruments, took him to Col. Trumbull, the painter of the "Signing of the Declaration of Independence," to ask whether he would be likely to succeed as an artist. The colonel advised him to stick to the law, as that profession was more remunerative than art; but his in-

clinations for drawing were so decided that, through the influence of his half brother, Dr. Dunnell, he was put into the hands of Mr. Herring, a portrait painter, who made him generally useful by employing him upon banners, transparencies, and other ornamental work of that kind. He remained nearly a year with Herring, and made his first attempt at oil painting under his tuition. On leaving his studio, he became a pupil of S. F. B. Morse, first president of the national academy, who then had a studio on the corner of Broadway and Pine street. He was admitted as a student at the national academy, and received the premium of a large silver medal for his drawings from the antique. At the age of 17 he became the subject of strong religious influence, was admitted a member of a Presbyterian church, and under the impulse of his religious enthusiasm determined to abandon the easel and devote himself to the ministry of the gospel. In pursuance of this scheme he went to Andover, Mass., to prepare himself for his theological studies. He remained there a very short time, when he went to Amherst, but subsequently returned to New York to resume his artistic pursuits. He spent a year in Albany painting portraits, and excited great expectations by the brilliancy of his color and the accuracy of his drawing. He was desirous of going to Europe, and had completed his arrangements for that purpose when he went to New York, and, meeting with a young lady for whom he formed a violent attachment, was married before he became of age, and remained at home. He at once took a high position as a portrait painter, and was admitted a member of the national academy. He was appointed to paint the portrait of Gov. Marcy for the New York city hall, and was sent for to paint that of John Quincy Adams for Faneuil hall in Boston. Beside portraits, he executed several historical compositions, among which were a "Holy Family," now in the Boston Athenæum, "The Wife's Last Visit to her Condemned Husband," and "The Infancy of Henri IV." In the midst of his growing popularity he had to contend with a terrible domestic calamity which resulted in his procuring a divorce from his wife. After this event he married again, went to Boston to reside, painted there a large number of portraits, and returned to New York, where he remained two years, and then went to Europe, residing 11 years in Florence and Rome. Having while in Rome procured a divorce from his second wife, he married again, and returned to New York in the autumn of 1860, where he continues to reside. During his residence in Italy he painted the portraits of many distinguished Englishmen and Americans, and produced his two "Venuses," his "Moses and Aaron on Mount Horeb," the "Flight into Egypt," the "Infant Bacchus," and other works. His copies of Titian, whose method of painting he professes to have discovered, were so remarkably like the originals, that one of them was stopped by

the authorities at Florence under the belief that it was the original painting. Since his return to New York he has delivered a course of lectures on art at the rooms of the mercantile library, and has published a "New Method of Measuring the Human Body," based upon the models of the antique.

PAGES. See GARNIER-PAGES.

PAGET, LORD. See ANGLESEA, MARQUESS OF. PAGODA, a kind of temple common in China and Indo-China, and especially in Burmah. In China pagodas form conspicuous and characteristic features of the scenery, and are generally towers 9 stories in height. The most celebrated of these was the porcelain tower at Nanking, which was destroyed by the rebels in 1856. This building was begun in 1412 and finished in 1431, and, having been erected as a monument of gratitude to an empress of the Ming dynasty, was called the temple of gratitude. It was octagonal in form and 236 feet in height, inclusive of an iron spire 80 feet high which surmounted it, and from the summit of which 8 chains depended, to each of which were attached 9 bells, while to each angle of the lower roofs a bell was attached, making the total number of bells 144, which tinkled in harmony to every breeze. The most striking peculiarity of this pagoda, however, was that its brick walls were covered with porcelain, producing a singular brilliancy of effect. Almost every town in China possesses one or more of these structures, all alike in design, but differing in dimensions and in the richness of the materials and ornaments. Fergusson, in his "Handbook of Architecture," says: "I cannot but think that the tapering octagonal form, the boldly marked divisions, the domical roof, and the general consistence in design and ornament of these towers, entitle them to rank tolerably high among the tower-like buildings of the world." The Burmese pagodas are square edifices of great extent, the base comprising porticos and central chambers, and terminating upward in octagonal or polygonal straight-lined pyramids or spires. The principal of these temples is called Khomado, and is situated on the bank of the Irrawaddy nearly opposite Ava. It is 160 feet high, surmounted by a spire 22 feet in height and 15 in diameter. The circumference of its base is 944 feet, and it is surrounded by a stockade of dwarf pillars of sandstone about 5 feet in height and 802 in number. The next great pagoda of Burmah is the Shoemadoo at Pegu, which rises to the height of 361 feet with a diameter at the base of 395 feet. At Rangoon is another called the Shoedagong, which resembles in size and plan the Shoemadoo. Throughout Burmah these edifices abound, varying from the dimensions of those already mentioned to 80 feet high.

PAHANG, or PAANG, a Malay state on the E. side of the peninsula of Malacca, bounded N. by the state of Tringany, E. by the China sea, S. by Johore, and W. by Salengore, extending from lat. 2° 10' to 4° 15' N., and from

the central range of mountains which traverse the peninsula to long. 104° E.; area, about 15,000 sq. m.; pop. estimated at 20,000. The chief town, which gives the name to the state, is situated on the left side of a small river, in lat. 3° 40' N., and is little better than a collection of huts, with a village on the opposite bank inhabited principally by Chinese. The coast is indented by several fine bays with sandy beaches, and numerous islands extend off it to the distance of 80 m. Some of these islands are of considerable size and mountainous, while many are small and low, and the N. E. sides of all are worn into cliffs and caverns by the action of the monsoons from that quarter. Most of them are covered with forests of large timber; few are barren, and some are covered with turfy grass. On the mainland the country is mountainous, the highest peak having an elevation of 3,221 feet. The Pahang and the Indau are the only navigable rivers, and they only admit boats or native craft. The geological formation consists of granite, sandstone, shale, and clays; and that of some of the islands is the same, while a few consist of trap rock. Iron, gold, and tin are found. The country bordering the sea is covered with forest, and the scenery is very beautiful; but the interior is little known. The exports consist of gold, tin, timber, gutta percha, damar, and rattans. The population is composed of civilized Malays, several tribes of the same race in a wild state, some tribes of oriental negroes, and about 3,000 Chinese. The rajah is nominally dependent on the sultan of Johore. The Portuguese called the country Pam.

PAHLEN, a noble family of Courland, whose origin has been ascribed to Pomerania and to Livonia. In Russian history several members of the family have acted conspicuous parts. In 1679 JOHN was created a baron by Charles XI. of Sweden. In the Turkish war of 1769 PETER (born in 1746, died in 1826) fought under Rumiantzoff, was made colonel and subsequently major-general, and was prominent in the storming of Otchakov in 1788. In 1790 he was sent as ambassador to Stockholm, and when Courland came into the possession of Russia in 1795 he was appointed its governor. The czar Paul raised him to the dignity of a count in 1799, and created him a general of cavalry and military governor of St. Petersburg. He was a leading actor in the conspiracy to dethrone the czar, which resulted in the assassination of Paul on the night of March 28, 1801. Regarded with distrust and aversion by Alexander, he retired to an estate near Mitau, where he passed the rest of his life, forgotten.—His son PETER, born about 1775, was one of the most distinguished generals in the war against Napoleon. In the campaigns of 1812 and 1813 he led a cavalry division, but was badly beaten at Nanig by the French, while commanding Wittgenstein's advanced guard. In 1827 he was made general of the cavalry, and achieved distinction in the Turkish war of the following 2

years. He also participated in the campaign in Poland in 1831, from 1835 to 1841 acted as ambassador at Paris, and in 1849 was appointed general inspector of all the cavalry, which office he still holds. His brother PAUL also chose the profession of arms, and took part in the various wars of Russia. Another brother, FREDERIC, has been Russian ambassador at Washington and Munich; in 1829, along with Count Orloff, he negotiated the treaty of Adrianople, and in 1834 became a member of the privy council.—Baron MATTHEW, who belongs to a collateral branch of the family, was a colonel at the taking of Lüneburg in 1813, and from 1830 to 1845 was governor-general of Livonia, Esthonia, and Courland. He is now general of cavalry, senator, and attached to the department of military affairs.

PAINE. I. ELIJAH, LL.D., an American jurist, born in Brooklyn, Conn., Jan. 21, 1757, died in Williamstown, Vt., April 28, 1842. He was graduated at Harvard college in 1781, and, after studying law, removed to Vermont in 1784, where he became extensively connected with the development of that state. He constructed a turnpike of about 20 m. over the eastern spurs of the Green mountains, and a manufactory of broadcloths, at a cost of \$40,000, at Northfield, then a wilderness. These works were undertaken, as he said, as much for the general interest of the state as for his own. The turnpike, indeed, he ultimately gave to the state. He was also extensively engaged in agricultural enterprises. He was elected in 1786 a member of the convention to revise the constitution of the state, and acted as its secretary. In 1789 he was one of the commissioners to adjust the claims between New York and Vermont. He was a member of the state legislature from 1787 to 1791, at the end of which term he was appointed a judge of the supreme court of the state, and held the office till 1794, when he was elected to the U. S. senate. At the expiration of the 6 years' term in 1801 he was reelected; but being simultaneously appointed a judge of the U. S. court for the district of Vermont, he resigned the senatorship. He continued on the bench until a few weeks before his death. Judge Paine was an earnest promoter of education, and a trustee of Dartmouth and Middlebury colleges and of the university of Vermont. He was also president of the Vermont colonization society, and a member of the American academy of arts and sciences, of the American antiquarian society, and of other learned associations. II. MARTIN, M.D., LL.D., an American physician, son of the preceding, born in Williamstown, Vt., July 8, 1794. He was graduated at Harvard college in 1813, studied medicine in Boston with Dr. John Warren, and practised in Montreal, Canada, from 1816 to 1822, when he removed to New York. Here he soon acquired a large practice. He participated actively in the treatment of the epidemic malignant cholera of 1832, during the prevalence of which he ad-

dressd a series of letters upon the disease to Dr. J. C. Warren of Boston, which were published in the periodicals of the day, and subsequently collected into an 8vo. volume, entitled "The Cholera Asphyxia of New York." Dr. Paine's next scientific work was "Medical and Physiological Commentaries" (2 vols. 8vo., 1840; vol. iii., 1844). In 1842 he published a work on "Materia Medica and Therapeutica," upon an original plan, and in 1847 a work entitled "The Institutes of Medicine," which has reached a 6th edition. The "Institutes" and the "Commentaries" have received, it may be said, almost unanimous commendation from the medical press in Europe and America. In 1848 he published "The Soul and Instinct distinguished from Materialism," the essential parts of which were subsequently incorporated in his "Institutes of Medicine;" and in 1852 he prepared a memoir of his son Robert Troup, embracing numerous academic essays and letters, privately printed in a superb quarto of 1,000 copies, and a single copy in folio designed for the library of Harvard college, at which institution his son was graduated in 1851, the year of his death. In 1856 Dr. Paine contributed an elaborate essay on "Theoretical Geology" to the "Protestant Episcopal Quarterly Review" (New York), directed against the geological interpretations of the Mosaic narrations of creation and the flood. This work has also appeared in a distinct form. In 1841 Dr. Paine united with 5 other medical gentlemen in establishing the university medical college (the medical department of the university of New York), in which he has been permanently a professor, having held for many years the chair of the institutes of medicine and materia medica, and more recently that of therapeutics and materia medica, which he now occupies. During the session of the legislature in 1854 he waited upon that body at Albany, and became a prominent agent in effecting a repeal of the law which rendered dissections of the human body a state prison offence, and of legalizing the pursuit. He is a member of many of the principal learned societies in Europe and America. III. ELIJAH, brother of the preceding, an American jurist, born in Williamstown, Vt., April 10, 1796, died in New York, Oct. 6, 1853. He was graduated at Harvard college in 1814, entered the law school of Litchfield, Conn., immediately afterward, and having been admitted to the bar established himself in the city of New York. He was associated with Henry Wheaton, whom he assisted in the reports that bear Wheaton's name. The 1st volume of the U. S. circuit reports that bear his own name was published under his supervision, and there has been a posthumous volume; and in 1830, in connection with John Duer, he published "Practice in Civil Actions and Proceedings in the State of New York." In 1850 he was elected a judge of the superior court, and held the office till his death. While upon this bench he sustained by an elaborate decision, in a case involving the

title to 8 slaves, the constitutionality of the statute of the state of New York that liberates the slave when brought by his owner within the state.

PAINE, ROBERT TREAT, an American statesman, and a signer of the declaration of independence, born in Boston, March 11, 1781, died there, May 11, 1814. He entered Harvard college at the age of 14, and after graduating studied theology, and acted in 1755 as chaplain of the troops on the northern frontier. Subsequently, after a visit to Europe on mercantile business, he studied law, supporting himself meanwhile by teaching school, and after being admitted to the bar established himself in Boston. Having removed to Taunton, he was a delegate from that town in 1768 to the convention called by leading men in Boston, after the dissolution of the general court by Gov. Bernard for refusing to rescind the circular letter to the other colonies. In 1770 he came more prominently into public life by conducting, in the absence of the attorney-general, the prosecution against Capt. Preston and his men for firing on the inhabitants of the city, and by his management of the case added much to his reputation. In 1773, and again in 1774, he was chosen as a representative from Taunton to the general assembly of Massachusetts, and in the latter year was made a delegate to the continental congress. In 1775 he was reelected, and was appointed one of the committee of three deputed to visit Gen. Schuyler's army on the northern frontier. He was a delegate to the congresses of 1776, 1777, and 1778, and occupied at the same time important stations in the government of Massachusetts, being in 1777 speaker of the Massachusetts house of representatives, and attorney-general of the state. In 1779 he was a member of the executive council, and was a delegate to the convention, and one of the committee which formed the constitution of the commonwealth. When, in October of the following year, this constitution was adopted, and the government organized according to its provisions, Mr. Paine was chosen attorney-general, and held that office until 1790, when he became a judge of the supreme court. In 1804 he resigned on account of deafness and infirm health. The same year he was a state councillor, but shortly afterward retired from public life. The strictness with which he performed the functions of attorney-general gained him a reputation for undue severity. He was one of the founders of the American academy, established in Massachusetts in 1780.—ROBERT TREAT, JR., an American author, son of the preceding, born in Taunton, Mass., Dec. 9, 1773, died in Boston, Nov. 13, 1811. His name was originally Thomas Paine, but in 1801 it was changed by act of the legislature to that of his father, when he remarked that he now had a "Christian" name, in allusion to Thomas Paine the infidel. He entered Harvard college in 1788, and while there was distinguished for his familiarity with the an-

cient languages and his literary abilities, especially in poetry. After his graduation he entered the counting house of Mr. James Tisdale, but soon left it, and in Oct. 1794, started a semi-weekly newspaper called the "Federal Orrery." While in mercantile business, according to his biographer, "he made entries in his day book in poetry, and once made out a charter party in the same style;" and at the same time he contributed verses to the "Massachusetts Magazine," and subsequently wrote theatrical criticisms. In Feb. 1796, he married a Miss Baker, an actress, and this produced for a time a breach between himself and his father. In 1796, upon taking the degree of A.M., he delivered a poem on "The Invention of Letters," which brought him in \$1,500, being more than \$5 a line. The following year he sold his newspaper, which from his neglect of editorial duties had become unprofitable; and the same year a poem entitled "The Ruling Passion," delivered before the Phi Beta Kappa society, yielded him \$1,200. In 1798 he wrote the celebrated song of "Adams and Liberty," for which he received \$750, or more than \$11 a line; and in 1799 he delivered an oration on the first anniversary of the dissolution of the alliance with France, for which he was complimented by Washington. Soon afterward he gave up his position as "master of ceremonies" at the theatre, an office which had been created for him in the days of his disagreement with his father, and his exclusion from fashionable society in consequence of his marriage. Turning his attention to law, he entered the office of Mr. (afterward Chief Justice) Parsons at Newburyport, and there delivered, Jan. 2, 1800, a eulogy on Washington. Admitted to the bar in 1802, he commenced practice in Boston with great success; but soon resuming his old acquaintance with the players, and his former unsettled mode of life, he passed his last days in misery and destitution. His works were collected and published by Mr. Charles Prentiss in 1812 (1 vol. 8vo., Boston).

PAINE, THOMAS, an American political writer, born at Thetford, county of Norfolk, England, Jan. 29, 1737, died in New York, June 8, 1809. At the age of 18 he was taken from school, to assist his father, a Quaker, at stay making. About 1755 he shipped in the privateer King of Prussia; and in 1759 he settled at Sandwich, worked at his trade, preached occasionally as a dissenting minister, and married. The following year he removed to Margate, where his wife died. In 1764 he was in the excise in his native town; but being dismissed from office in 1765, he went to London, where he obtained employment as teacher in an academy, devoting his leisure moments to the study of the natural sciences. In 1766 he was restored to the excise. He removed to Lewes, in Sussex, in 1768, where he took a second wife in 1771, and carried on business as grocer and tobaccoist. In 1773 he wrote "The Case of the Officers of the Excise," a pamphlet which introduced him

to Oliver Goldsmith. He failed in business, and his effects were sold in April, 1774; was dismissed a second time from the excise; separated from his wife in May, and went to London, where he became acquainted with David Williams, the noted political and deistical writer, by whom he was introduced to Benjamin Franklin, then in London, who advised him to try his fortunes in the new world. Paine accordingly sailed for America, Oct. 1, 1774, carrying with him recommendatory letters from Dr. Franklin to Bache, his son-in-law, and others, and arrived in Philadelphia in the beginning of December. In Feb. 1775, Mr. Aitkin of Philadelphia employed him as editor of the "Pennsylvania Magazine," the first number of which had been issued the preceding month. His contributions to this work appeared with the signature "Atlanticus," and were much commended at the time. In Sept. 1775, he commenced his "Common Sense," which is said to have "severed the last link that bound the colonies to the mother country." On Oct. 18 he published in Bradford's "Pennsylvania Journal," "Serious Thoughts" upon slavery, &c., in which "he hesitates not a moment to believe that the Almighty will finally separate America from Britain," and hopes, when this is accomplished, "our first gratitude may be shown by an act of continental legislation which shall put a stop to the importation of negroes, soften the hard fate of those already here, and, in time, procure their freedom." The celebrated Dr. Rush of Philadelphia was so pleased with this essay that he sought an introduction to the author; but he did not, as is often asserted, suggest to Paine the idea of writing "Common Sense." At that time there was a great scarcity of gunpowder in the American colonies, Great Britain having totally prohibited its exportation to her rebellious subjects. Paine turned his attention to chemistry; set his talents to work to discover some cheap and expeditious method of making saltpetre; published his experiments for the benefit of the patriots in the Philadelphia journals; and formed an association whose object was to supply, gratuitously, the national magazines with powder. On Jan. 10, 1776, when "a reconciliation with the mother country was the unanimous wish of almost every American," a pamphlet, called "Common Sense," advocating the establishment of a republic of free and independent states, "burst upon the world," in the language of Dr. Rush, "with an effect which has rarely been produced by types and paper, in any age or country." It was immediately denounced as "one of the most artful, insidious, and pernicious of pamphlets." John Dickinson, a staunch supporter of the American cause, and author of the "Farmer's Letters," opposed the idea of independence, in a speech, as a member of the continental congress. The author of "Plain Truth," one of the many replies to "Common Sense," thought that "volumes were insufficient to describe the horror, misery, and

desolation awaiting the people at large in the siren form of American independence." Dr. William Smith, provost of the university of Pennsylvania, said in his "Cato's Letters," published in March, 1776: "Nor have many weeks yet elapsed since the first open proposition for independence was published to the world; it certainly has no countenance from congress," and "is only the idol of those who wish to subvert all order among us and rise on the ruins of their country." Soon after independence was declared, Paine volunteered into Gen. Roberdeau's division of the flying camp; and when their term of service expired, he went to Fort Lee, serving during that trying campaign as aide-de-camp to Gen. Greene. When Pennsylvania was distracted by parties on account of her constitution, Paine endeavored with his pen to bring the controversy to an end. He was not one of the authors of the Pennsylvania constitution of 1776, as he says, in a communication to the "Pennsylvania Packet," of March 18, 1777, that he "had no hand in forming it; nor did he know of its contents till he saw it published." On Dec. 19, 1776, when the stoutest hearts failed, Paine published his first "Crisis," which began with that phrase since so often quoted: "These are the times that try men's souls." This aroused the drooping ardor of the people; it was read at the head of every regiment; and the first fruit of the reanimated enthusiasm it produced was the battle of Trenton, 6 days after. "The Crisis," of which some 18 numbers were published, appeared at irregular intervals until peace was established. In April, 1777, on motion of John Adams, Paine was elected secretary to the committee on foreign affairs. The following winter he offered his services to the naval board at Trenton, to make one of a party of 4 or 5 that would set fire to the enemy's fleet in the Delaware. About this time (the winter of 1778), in a conversation with William Henry of Lancaster, Penn., he made the first proposition ever put forth in America for the application of steam to navigation. In Jan. 1779, while engaged in the preparation of a "History of the American Revolution," he commenced a series of letters in the "Pennsylvania Packet," denying the validity of Silas Deane's claims upon the American government; for doing this he was censured, unheard, by a faction in congress, and on the 8th of that month resigned his office of secretary. That the action of congress was disapproved, and Paine's conduct in exposing Deane was appreciated, may be seen by the fact that the annual town meeting held in Philadelphia in July, and presided over by Gen. Roberdeau, unanimously resolved to "support and defend Thomas Paine;" and in the following November Pennsylvania gave him a proof of her confidence, by electing him clerk to the general assembly. In 1780 he was dissuaded by Gen. Greene from going to England, where he intended to circulate his republican sentiments, hoping thus to create a panic in that

country, and more effectually aid the cause of America. Early in June of that year, a letter was received by the assembly of Pennsylvania, from Gen. Washington, stating that, notwithstanding his confidence in the attachment of the army to the cause of the country, he feared that their distresses would soon cause mutiny and discontent in the ranks. This letter was read by Paine, as clerk. A despairing silence pervaded the hall. At length one of the members said that it was in vain to contend any longer, and they might as well give up first as last. To dissipate the gloom, a more cheerful member moved an adjournment, which was carried. Paine, who knew that the assembly had neither money nor credit, felt that the voluntary aid of individuals could alone be relied upon. He accordingly wrote to Blair McClenaghan, a merchant of Philadelphia, explaining the urgency of affairs, and enclosed in the letter \$500, the amount of salary due him as clerk, as his contribution toward a relief fund. McClenaghan called a meeting next day and read Paine's letter; a subscription list was immediately circulated, and in a short time £300,000 Pennsylvania currency was collected. With this as a capital, the Pennsylvania bank (afterward expanded into the bank of North America) was established for the relief of the army. On July 4, 1780, the degree of A.M. was conferred upon Paine by the university of Pennsylvania. In Feb. 1781, he accompanied Col. Laurens to France, to negotiate a loan from that government, and arrived home Aug. 25, with \$2,500,000 in silver—a great help to Washington in the movement southward, which ended in the capitulation of Yorktown. In 1782 appeared his "Letter to the Abbé Raynal." The next year he accepted an invitation from Gen. Washington to partake of his hospitalities at Rocky Hill; and the successful experiment while there of setting a neighboring creek on fire, as performed by Gen. Washington, assisted by Paine, Gen. Lincoln, and Col. Cobb, is described in an essay on "The Cause of the Yellow Fever," which Paine published in New York in 1806, at the request of Thomas Jefferson. In Jan. 1785, he was elected a member of the American philosophical society, and in the following October received \$3,000 from congress as a testimonial of their appreciation of his services. His "Dissertations on Government" appeared in 1786. On April 26, 1787, he sailed for France, where he was cordially received by Buffon, La Rochefoucauld, De Chastellux, Malherbes, the abbé Morellet, and many other eminent men. He submitted the model of an iron bridge which he had invented to the academy of sciences at Paris, whose opinion of its merits was decidedly favorable. In September he visited his mother in England, and wrote the "Prospects of the Rubicon." In 1788 he resided at Rotherham in Yorkshire, superintending the erection of his iron bridge, of which Stephenson says: "If we are to con-

sider Paine as its author, his daring in engineering certainly does full justice to the fervor of his political career; for successful as the result has undoubtedly proved, want of experience and consequent ignorance of the risk could alone have induced so bold an experiment; and we are rather led to wonder at than admire a structure which, as regards its proportions, and the quantity of material employed in its construction, will probably remain unrivalled." This bridge was put up for exhibition in an open field at Paddington, and was afterward taken down and the materials used in the one which now spans the river Wear at Sunderland. Paine was in Paris when the Bastille was demolished, the key of which Lafayette gave him for presentation to Gen. Washington. It is now among the relics at Mount Vernon. Paine, who had partaken of Edmund Burke's hospitality at Beaconsfield, corresponded with him from Paris, not knowing that "the pensioner" was preparing his "Reflections upon the French Revolution," which appeared in Oct. 1790. Among the many replies to the "Reflections," by Lord Stanhope, Mary Wollstonecraft, Catharine Macaulay, Sir James Mackintosh, and others, Thomas Paine's "Rights of Man" was the only one that really engaged the public attention. The first part of that work was dedicated to Washington, and appeared in March, 1791; the second part, dedicated to Lafayette, was published in Feb. 1792. Paine, in his "Wars of the Revolution," says: "Editions were multiplied in every possible form and size; it was alike seen in the hands of the noble and of the plebeian, and became at length translated into the various languages of Europe." It is supposed that at least 100,000 copies of the "Rights of Man" were published. In 1792 he gave the revolutionary society of England an order on Jordan, his publisher, for £1,000, to be applied in the furtherance of their objects. In Sept. 1792, a deputation from France announced to Paine his election to the French national convention from the department of Calais. He immediately left England to take his seat, meeting with a triumphant reception in Paris. The following December his trial for sedition took place in London, and, not appearing to receive his sentence, he was outlawed. In the national convention Paine generally voted with the Girondists. He was associated with Brissot and Condorcet on the committee that framed the constitution of 1793. As a member of the convention, he advocated the trial of Louis XVI.; but when the sentence of that unfortunate monarch came up for discussion, Madame de Staël says: "Thomas Paine alone proposed what would have done honor to France if it had been accepted—the offer to the king of an asylum in America." In Dec. 1793, the convention passed a decree for the expulsion of all members who were foreigners by birth. This was soon followed by another for the imprisonment of all persons in France born in England.

Under this decree, Thomas Paine was arrested and thrown into the Luxembourg. On his way to prison he placed the manuscript of the first part of his "Age of Reason" in the hands of his friend Joel Barlow, the American poet. His confinement lasted from January to November, 1794. When he was first arrested, the Americans in Paris went in a body to apply for the release of "the apostle of liberty in America," as they styled him; but they were unsuccessful. A few months after the death of Robespierre, James Monroe, the American minister in France, procured his liberation, and tendered him a home in his own family, which Paine enjoyed for about 18 months. In Dec. 1794, he resumed his seat in the national convention, upon the invitation of its members. In 1795 the second part of the "Age of Reason" appeared. This work is denounced as atheistical; but it expressly inculcates a belief in God, Joel Barlow, in a letter to Cheetham in 1809, said that "Paine's religious opinions were those of three fourths of the men of letters of the last age, and of nearly all those of the present." In the "Age of Reason" he says: "I believe in one God and no more; and I hope for happiness beyond this life. I believe in the equality of man; and I believe that religious duties consist in doing justice, loving mercy, and endeavoring to make our fellow creatures happy." He then states what he does not believe, and his reasons therefor. In April, 1796, he published his essay "On the English System of Finance," and in the following July his "Letter to General Washington," in which he accuses him of ingratitude in not attempting to procure his liberation from the Luxembourg. "Agrarian Justice," and a "Letter to the People and Armies of France," appeared in 1797. This year he assisted Larevellère-Lepaux and Haty in founding the society of theophilanthropists. When Napoleon meditated a descent upon England, by means of gun boats, he secured the services of Thomas Paine to establish, after the conquest, a more popular government. In 1802 Paine resolved to return to the United States. In this republic, in former times, he had met with the highest respect; the most prominent men had paid homage to the influence of his pen; and his eminent services had been freely acknowledged. New York had presented him, during the revolution, with the Devoe estate at New Rochelle, Westchester co., consisting of 800 acres of valuable land, with the necessary buildings. In consideration of the fact that "Thomas Paine did, during the whole progress of the revolution, voluntarily devote himself to the service of the public, without accepting recompense therefor; and, moreover, did decline taking or receiving the common profits which authors are entitled to on the sale of their literary works, but relinquished them for the better accommodation of the country, and for the honor of the public cause," Pennsylvania gave him £500. New Jersey gave him a small estate at Borden-

town. Virginia was about to grant him a tract of land valued at upward of £4,000, when he published his "Public Good," denying her claims to the north-western territory; and, though Washington, Madison, Lee, and Patrick Henry exerted themselves in his favor, he lost the grant by a single vote. He arrived at Baltimore, after an absence from the United States of 15 years, on Oct. 30, 1802. Thomas Jefferson invited him to Monticello, where he left a favorable impression. At Washington he was cordially received; and while there he wrote his "Letters to the People of the United States." On his way to New York he was grossly insulted by the federalists at Trenton. His admirers in New York and Philadelphia honored him with public dinners; his enemies thought that he and Jefferson "should dangle from the same gallows." He finally settled in New York, occasionally passing a few months on his farm at New Rochelle. Just before his death he requested to be interred in a Quaker burial ground; but the Quakers refusing to permit this, his remains were taken to New Rochelle and there buried on his farm. In 1819 William Cobbett, the English reformer, violated the grave and took his bones to England, where they are now in the hands of a committee, who intend to honor them with a public funeral at some future day. A monument was erected to his memory in 1839 within a few feet of the spot where he was originally buried.—In stature, Thomas Paine was about 5 feet 10 inches, and broad-shouldered. He was plain but dignified in his appearance. He wore his hair in a queue, with side curls, and powdered. His eyes were full and brilliant, and singularly piercing. In his manners he was easy and graceful. Though not a fluent speaker, among his friends and in private company his conversation was exceedingly fascinating. In mixed company he said little. The principal portraits of Thomas Paine, known in this country, are Charles Wilson Peale's, painted about the year 1780, and Romney's, painted in England in 1792, and engraved by Sharp; there is also a plaster bust taken by Jarvis in New York in 1805, while Paine resided with him. As a writer, Thomas Paine was always forcible, and often eloquent; his style, manner, and language were well calculated to interest the passions, and rouse the active powers of human nature. Botta, the historian, doubted whether any "writer ever possessed in a higher degree the art of moving and guiding the multitude at his will;" and Jefferson acknowledged that "no writer has exceeded Paine in familiarity of style, in perspicuity of expression, happiness of elucoidation, and in simple and unassuming language." Among the biographers of Paine, the most prominent are George Chalmers, F.R.S. (under the assumed name of Francis Oldys, 1791); William Cobbett (1796); James Cheetham (New York, 1809); Clio Rickman (1819); W. T. Sherwin (1819); and Gilbert Vale (New York, 1842).—The most complete

edition of Thomas Paine's works is that by J. P. Mendum (Boston, 1856), which however contains several articles not by him.

PAINESVILLE, a village and the capital of Lake co., O., on Grand river (crossed near here by a stone viaduct of 4 arches, 800 feet long and 83 feet high), 3 m. from the best natural harbor on Lake Erie, and on the Cleveland, Painesville, and Ashtabula railroad, 29 m. N. E. from Cleveland; pop. in 1860 within the corporate limits, 2,624. It contains a court house, gaol, 2 flouring mills, 2 founderies, 2 engine factories, 2 tanneries, a bank, 3 hotels, 6 churches, a large union school, the Lake Erie female seminary, and 2 weekly newspaper offices. The business portions have been entirely rebuilt of brick within 8 years, having been destroyed by 8 disastrous fires.

PAINTERS' COLO. See COLO. and LEAD.

PAINTING, the art of representing objects by means of light and shade or color upon an even surface. Whatever importance such objects possess for the purposes of science, to the painter they present five qualities or elements, as follows: shape (or form), size (or quantity), light and shadow (or gradation), local color (or hue), and texture. No object in nature is without these distinctive characteristics, and no object in nature has other than these for pictorial treatment. Hence a painting is meritorious in the degree that it exhibits these traits with accuracy. Of the various theories respecting the origin of the art, that seems the most natural which makes it coeval with the invention of writing. Goguet in his *Origine des loix* notices the fact that the earliest people made their first essays in writing by representing to the eye the objects they wished to impress upon the mind; and so far as observation has demonstrated, this remark holds good of all primitive races. No date can be assigned to the commencement of this practice, and, as Haydon has remarked, "in what country painting first originated is nearly as difficult to discover, as it is to find a country where it never existed at all." Dismissing for want of authentic materials any inquiry into the progress of the art among the Chinese, the Hindoos, the Persians, the Assyrians, the Phœnicians, and their cognate races, by whom it was probably never developed beyond the rudest stages, we may commence the history of painting with Egypt, where it can be traced back to a very remote antiquity. Egyptian paintings are comprised in three classes, those on the walls of tombs and temples, those on the cases and cloths of mummies, and those on papyrus rolls, the first being the most numerous and meritorious, although none of them can be properly considered works of art, but rather the symbolic writings which record the social, religious, and political life of the people. Both sculpture and painting were originally practised in conjunction, the latter being the subordinate art, and the earliest employment of the painter was to color statues, bass-

reliefs, and intaglios or sunk reliefs. To this succeeded the execution, under a strict code of conventional rules prescribed by the priesthood, of those elaborate works which now afford such vivid illustrations of the manners and customs of the Egyptians. According to Pliny, painters and sculptors were forbidden to introduce any change or innovation into the practice of their respective arts, or in any way to add to them; and hence the monotonous character of Egyptian art, the perpetual recurrence through thousands of years of similar types of form, and the absence of any progressive development such as may be witnessed in the productions of other races. It was, however, doubtless owing to this dependence upon established canons that the artists were enabled to impart to their works that character of stability and unity of purpose which so impresses the modern traveller on the banks of the Nile. The technical merits are slight. The imitation of nature was never carried beyond an outlined diagram arbitrarily colored; of ideal beauty they are utterly destitute; and perspective, chiaroscuro, and the science of composition seem to have been unknown. Men and women were generally painted red, animals brown, birds blue and yellow, and other objects according to similar arbitrary rules, in utter disregard of their natural appearance. Sometimes a varnish of glue or resin was applied to the finished picture, which may account for the freshness which the colors still retain. The most flourishing period of Egyptian art was that from about 1400 B. C. to the Persian conquest in 525 B. C., after which a slow but gradual decline is observable, until in the early part of the Christian era the art of the Greeks becomes predominant.—In common with other arts, painting appears to have been established in Greece mainly through communication with Egypt and Asia, and previous to the commencement of the 5th century B. C. it was chiefly ornamental or representative, its application being limited to the decoration of temples, the coloring or imitation of bass-reliefs, and similar purposes. With the Persian wars, the great promoter of intellectual activity among the Hellenic races, it began to assume its peculiar Greek character, and to be practised as an independent art; and from that era until after the death of Alexander it received its most perfect development. The whole period preceding the Persian invasion may be said to constitute the mythic age of Greek art, during which a slow but gradual approximation to excellence was observable, the motive for which must be traced to the character of the people and of their religion. A love of beauty was with the Greeks a principle of religion; their deities were models of physical excellence, and their own habits tended to bring the human form to a similar degree of perfection. Hence, when painting and sculpture were made to subserve the cause of religion by representing to the

eye the material forms of Greek mythology, the artist strove to clothe them with the attributes of majesty, loveliness, or grace; and this effort, continued through successive ages among a people of remarkable intellectual endowments, developed art from its original Egyptian rudeness and arbitrary conventionalism into life, motion, and liberty. The Egyptian artist reproduced for ages a fixed type of the human figure, while his Greek contemporary aimed at an ideal perfection, which made him in a measure the arbiter of form. With the arrival of Polygnotus of Thasos in Athens, 468 B. C., commences the authentic history of Greek art, and the supremacy of Athens as the capital of the arts, although few of the great painters of Greece were natives of that city. Aristotle calls him *ῥεογραφός*, the painter of character, and he is mentioned by other Greek writers as one of the most distinguished painters of antiquity in the essentials of form, expression, and color. He was employed to decorate various public buildings in Athens, and also executed 8 famous pictures illustrating Homeric episodes for the Lesche, a public hall near the temple of Apollo at Delphi, which 600 years later excited the wonder and admiration of Pausanias. These works, however, can scarcely be called historical in the modern acceptance of the word, as the events and objects were indicated rather than represented, and no attempt was made at dramatic development in composition or local truth and circumstantial detail of execution. Other celebrated painters of the Athenian school, of which Polygnotus is considered the founder, and contemporary with him, were Dionysius of Colophon, an excellent portrait painter, of whom Aristotle says "he painted men as they are;" Micon, distinguished for his horses; Panæus, and Onatas of Ægina. Somewhat later flourished Apollodorus, who about 404 B. C. developed the principles of light and shade. According to Pliny, he was the inventor of tone. Painting, which had hitherto been sculptural in its character, now took a more dramatic range, and to the school of Athens succeeded that called the Asiatic or Ionic, of which Zeuxis, Parrhasius, and Timanthes were the chief exemplars. It constitutes what may be called the second phase of Greek painting, the school of Polygnotus forming the first, and was characterized by more unity of sentiment and action, and a close imitation of the local and accidental appearances of objects. Zeuxis and Parrhasius excelled in form and in the representation of material beauty, and, if inferior in simplicity and expression to Polygnotus, greatly surpassed him in the technical parts of their art. The "Helen" of Zeuxis was one of the wonders of ancient art, and the numerous pictures by Parrhasius of deities and heroes attained a high importance. Eupompus of Sicyon, the last very distinguished painter of this period, founded about the time of Philip of Macedon the Sicyonian school of painting, characterized

by scientific cultivation, artistic knowledge, and great ease and accuracy in drawing, and which constituted the third and last phase of Greek painting, or, as it has been called, the epoch of refinement. The form now became paramount over the essence, and technical excellence reached its limit. The chief painters of this time were Pamphilus, chiefly distinguished as a teacher of the theory of his art; his pupils, Apelles, Melanthius, and Pausias, the first pre-eminent not less for grace or beauty of form than for his power in sublime subjects, the last one of the first to practise encaustic painting; Protogenes of Rhodes, a rival of Apelles; Nicias, who excelled in light and shade; Euphranor, excellent in many departments; Nicomachus and Aristides of Thebes, the former remarkable for boldness of execution, and the latter, according to Pliny, the greatest master of expression in all Greece; Theon of Samos, and Athenion of Maronea, beside many others, extending over a period of upward of a century. Of these the most famous was Apelles, whose celebrated contest of drawing with Protogenes is frequently cited by ancient critics as an illustration of the degree of technical skill acquired by each artist. From the time of Alexander art rapidly deteriorated, and subsequent to the middle of the 8d century B. C. scarcely another name of note occurs. In the place of mythological or epic stories, the artists painted caricatures, low or domestic subjects of the class called *genre*, and obscene pictures, or contented themselves with reproducing feeble copies of the works of their predecessors. At the period of the Roman conquest painting exhibited little vitality, and the spoliation of public buildings and galleries to adorn the porticos and temples of Rome tended to crush the art everywhere in Greece. Greek paintings were executed in distemper, with glue, milk, or white of egg, and in encaustic, upon wood, clay, plaster, stone, parchment, and during the latest period upon canvas. Wood panels with a ground of plaster were most commonly employed, and in the late stages of the art fresco painting attained some perfection. Various species of varnish appear to have been known, and Pliny says that Apelles was indebted for his brilliant coloring to a liquid called *atramentum*, with which he covered his pictures; whence Sir Joshua Reynolds has concluded that he was a master of the art of glazing. Down to the time of Apelles 4 principal colors were used, white, red, yellow, and black, from which all the necessary hues and tints were composed. The "Aldobrandini Marriage," now in the Vatican, supposed to resemble a picture by Echion of the Sicyonian school, the "Achilles discovered by Ulysses" and "Achilles surrendering Briseïs," both found at Pompeii, and a few others, although probably feeble imitations of older works, sufficiently attest the high character of Greek art in its prime. The mosaic of the *casa del Fauno* at Pompeii, representing the "Battle of Issus,"

now in the Museo Borbonico in Naples, is the finest ancient picture extant, with respect to composition, foreshortening, and perspective.—Of Etruscan painting, as exemplified by specimens found in sepulchral chambers at Tarquinii, Caere, and elsewhere, little need be said. It is essentially Greek in its style and characteristics, and to a limited extent shows similar stages of development and decay.—The Romans received their art directly from Greece, and, though eager and intelligent collectors of the works of the early masters of that country, had no independent school of painting. There does not seem to have been a single Roman painter of eminence; but inferior Greek artists abounded in the Italian peninsula, and particularly in the capital, and the best Roman paintings were probably executed by them in the degenerate style which marked the decline of the arts in Greece. These consisted chiefly of portraits, ornamental or decorative work, and copies of the masterpieces of antiquity. It is worthy of remark, however, that the Romans were the first to cultivate portrait painting as a distinct branch of the art. To such a depth of degradation did painting finally descend among them, that it was practised chiefly by slaves, and the painter was estimated by the quantity of work he could do in a day. But the treasures of art accumulated in Rome by successive generals and emperors, from the time of Marcellus downward, made the city, as Cassiodorus has expressed it, "one vast wonder." Most of these were in turn transferred to Constantinople by Constantine and his successors, and the remainder disappeared in conflagrations or in the disorders which marked the period of the exarchate. Not one authenticated painting by any of the great masters of antiquity is now known to be in existence. In one respect the practice of painting in Italy differed from that of Greece. In the latter country the art was essentially religious, and was mainly confined to temples and public buildings; but the Romans early familiarized it with the household, and no dwelling, whether palatial or strictly domestic, was considered complete unless every apartment or portion had its painted decorations signifying the use for which it was designed.—While art in its ancient seats was thus passing through the last phases of what has been called its "age of decrepitude," Christianity had taken root in many parts of the world; and although the new religion, unlike the old, needed no direct alliance with art, and its followers, in their detestation of paganism, denounced the carvers of graven images as servants and emissaries of Satan, the influence of so many previous ages of civilization could not be at once extinguished, and the early Christians before the time of Constantine attempted the visible representation of sacred personages and actions, by means of symbols and mystic emblems. Thus the lamb typified Christ; the vine and its branches, Christ and his disciples; the fish,

baptism; the ship, the church; and the cross, redemption. The art even to this limited extent, however, was practised not for the pleasure it would excite, but as a means of inculcating religious principles; and when, as Christianity gained converts, it became safe to venture beyond the limits of mere symbol, and to depict Christ as the Good Shepherd, care was taken to eschew the beauty of features and body lavished by pagan artists upon the representations of their deities. Indeed, while Jewish converts preponderated in the early church, the Saviour was represented, on the authority of certain passages in the Old Testament, as devoid of all beauty, "not like the gods of the Pantheon catching the eye by outward attractions, but conquering the heart by the power of his word." It was not until the close of the 8th century that Adrian I. decided, in a papal bull, that Christ should be represented with all the attributes of divine beauty which art could lend him. Nearly a century previous, in 692, the council of Constantinople had authorized the direct human representation of the Saviour in place of the symbolical. The most interesting monuments of Christian art during the first 8 centuries are to be found on the walls or ceilings of the catacombs of Rome. In the catacomb of St. Calixtus were discovered many representations of scriptural stories, parables, and symbols, intermingled occasionally with some of the more innocent pagan allegories, and also a portrait of Christ as the Good Shepherd, the earliest known to have been painted, and which probably formed the type for others. Kugler ascribes to these works "much grandeur of arrangement" and "a peculiar solemnity and dignity of style." As distinguished from pagan works of the same or an earlier period, they may be said to exhibit more spirituality in the conception of the human form, holiness of expression and strength of character being preferred to beauty of features or body, and a strong predilection for natural objects, as animals, leaves, or flowers. When the establishment of Christianity by Constantine enabled the pious decorators of the early church to emerge from the gloom of the catacombs, they transferred their labors to the numerous edifices dedicated to the new religion. But before art had time to attain a healthy expansion under the new influences which were at work, or to assume a distinctive form, civil commotions and barbaric invasions intervened to check its development in Italy, and in the 6th century Constantinople became its principal seat. Mural painting in fresco or distemper now gave way to mosaic work, and for 4 or 5 centuries the most interesting remains of pictorial art are the mosaics in the churches and the miniature illuminations of Bibles and other sacred books. (See MOSAIC, and MINIATURE PAINTING.) During the 8th and 9th centuries the iconoclasts of the eastern church pursued a systematic destruction of works of art; but notwithstanding the disfavor into which Greek

artists and their works thereby fell, Constantinople remained from the 7th to the 13th century the great capital of the arts, and during that period the Byzantine style was predominant in every branch of art which the degraded taste of man permitted to be cultivated. Byzantine painting was practised almost exclusively for religious purposes, and about the commencement of the 9th century assumed a hierarchical stiffness of type which has descended unaltered to the present day, although genuine Byzantine pictures are now produced only in a few places in Russia and Greece. The characteristics of the school are length and meagreness of limbs, stiffness of figure, features almost void of expression, long and narrow eyes, a disagreeable blackish green coloring of the flesh, various conventional attitudes and accessories having no foundation in nature, and a profusion of gilding. The colors, though bright, were raw and crude, and commonly painted on a gold background. The painters were monks or persons connected with monasteries, who formed a sort of perpetual craft or guild for the manufacture of pictures; and the subjects were almost as fixed as the style, consisting of the Madonna and child throned, and representations of sacred history or allegory.—The capture of Constantinople by the Venetians in 1204, by promoting a greater intercourse between the Byzantines and Italians, is considered to have given the first impulse toward the revival of the arts in Italy and the West. Many Byzantine painters passed into Italy and Germany, carrying with them their technical methods and their types of form and color, which were followed more or less servilely by the Italians who studied under them; and at Venice, Pisa, and Sienna were planted early in the 13th century the germs of what subsequently became the leading schools of Italy. But while in the eastern empire the influence of an expiring faith was still manifest in the social relations, the literature, and the art of the people; in Italy, after centuries of turmoil, a new and vigorous civilization, largely impregnated with the Gothic element, but inspired and directed by Christianity alone, had appeared, under which it was impossible that art should not show a new development. The artist, sharing in the religious fervor with which every occupation was pursued, painted for the glory of Christianity and the good of his fellow men, and, finding the shrunken and withered forms of the Byzantine school insufficient for the purposes of his art, was led to a closer imitation of nature. One by one the familiar conventionalisms, which centuries of use had sanctified, were thrown off by bold innovators, until in the early part of the 16th century the culminating glory of the art was reached. The successive steps, however, were slow, with long intervals between, and not until the commencement of the 14th century can painting be said to have freed itself in any considerable degree from its Byzantine tram-

mels. Of the two arts, sculpture, under the lead of Nicola Pisano, the greatest artist of the 13th century, considerably preceded painting in the order of development. The painters were hampered by a mode of treatment handed down to them for centuries, and from which it was difficult at once to emancipate themselves; while the sculptors, ignorant as yet of the marbles of the Greeks, were obliged to employ as models the every-day objects which surrounded them. Hence of necessity there grew up among the latter a system of observation and study of nature which soon gave an original character to their works.—To Giovanni Cimabue, of Florence, who flourished between 1240 and 1300, it has been customary to ascribe the revival of painting in Italy, although Giunta da Pisa and Guido da Siena, who preceded him, had already given some indication of independence of feeling. Tuscany, however, was the seat of this revival, and for upward of two centuries the Tuscan schools maintained their ascendancy in Italy. Neither of these artists advanced much beyond the Byzantine traditions, and the chief merit of Cimabue undoubtedly consists in the fact that he discovered and fostered the genius of Giotto di Bondone, the first great painter of modern times, and the true regenerator of the art. With the commencement of the 14th century, the date of this master's first works of importance, the history of Italian painting properly commences; and in tracing its development each of the principal schools will be noticed in succession. The subject has already been treated at some length under the head of FRES- CO PAINTING, which formed the most important branch of the art in the 14th and 15th centuries; and for the characteristics and chief productions of individual painters the reader is referred to their biographies in this work.—The Tuscan schools, comprising the Siennese, Pisan, and Florentine, were in the 15th century merged in the last named, of which Giotto was the founder. Previous to his time the only real advancement in painting was the substitution of the human figure for its mere type or symbol. Giotto made the second great step of progress by rejecting the dark coloring which his predecessors had retained from their Byzantine models, and introducing that which was paler and more natural. His compositions also exhibit a better idea of grouping, and his figures more action and variety of position, the result doubtless of the new ideas of form suggested by the works of Nicola Pisano. He painted in the chief cities of Italy from Naples to Milan, and his mature works, such as the frescoes in the chapel of the Arena at Padua and in the Franciscan church at Assisi, retain no traces of the Byzantine style. His followers and imitators, forming what has been called the *scuola Giottesca*, for the most part confined themselves to the reproduction of the models left by their master, but some pursued the path he had opened to them with results

beneficial to the progress of art. Of the latter class, Taddeo Gaddi and Andrea Orcagna have been considered superior in dignity and grandeur to Giotto himself. Contemporary with Giotto, and scarcely less famous, were Simone Memmi of the Siennese school, the characteristics of which seem to have been force of expression and a tendency toward idealism, and Buffalmacco, of humorous memory, whose exploits as related by Boccaccio have survived almost every relic of his pencil. Other painters of the period were Angelo Gaddi, the son of Taddeo; Tommaso di Stefano, called Giotto; Spinello Aretino; Cennino Cennini, author of the oldest Italian treatise on painting; and Francesco da Volterra. None of these, however, advanced much beyond the point reached by Giotto. At the close of the century the influence of Giotto was discernible not in Tuscany alone, but throughout Italy and even beyond the Alps. But painting was nevertheless in a very undeveloped state. Portraiture was rarely practised, landscape painting as a branch of art was unthought of, and no true standard of form had been established. The purposes to which painting were applied were almost wholly of a religious character, and when subjects from pagan mythology or classic history were introduced, it was to illustrate the truth of Christian revelation or the doctrines of moral theology. Believing that they shared with the clergy the task of instructing the people, the artists aimed at a truthful representation of their subject rather than at technical skill; and on this account their art, imperfect and conventional as it was, has an impressiveness of character which the works produced during the splendid era of Raphael fail to present. In the 15th century painting advanced very considerably, and toward its close Florence, under the munificent sway of the Medici, became one of the most splendid art capitals of any age. Pietro della Francesca and Paolo Uccello developed the science of perspective, and Masolino da Panicale that of chiaroscuro. The productions of Lorenzo Ghiberti, the sculptor of the famous gates of San Giovanni in Florence, also gave new vigor to the imitative principles established by Giotto; and to his influence perhaps the peculiar excellence of Florentine art may be traced. But to Masaccio, who discarded the conventional types of the human form and made his studies directly from life, is due the credit of establishing the great era of the pictorial art of this century; and until near the time of Raphael his conceptions of form remained the standard. Contemporary with or immediately succeeding him were Fra Angelico da Fiesole, less distinguished for any external quality of art than for the deep religious sentiment of his works; Filippo Lippi, one of the earliest painters of the naturalistic as distinguished from the mystical school, as that class of masters has been called who made religion the end and object of their art;

Benozzo Gozzoli; Filippino Lippi; Antonio Pollajuolo, the first who studied the dead subject for the purposes of design; Domenico Ghirlandaio, the master of Michel Angelo; Cosimo Rosselli, Sandro Botticelli, Luca Signorelli, Andrea Verocchio, and Andrea Castagno, one of the first who practised oil painting after the manner of the Van Eycks. With Leonardo da Vinci, a master accomplished in many arts beside painting, commences another epoch, in which Masaccio's conceptions of form were combined with dramatic compositions, with local color, and with light and shade, as illustrated in the famous "Last Supper" in the convent of Sta. Maria delle Grazie at Milan. The earnest, simple faith, and the spiritual treatment of the early painters now gave way in a measure to the realistic tendencies of the age. Less was left to the imagination and feelings, and in place of sacred history and legends of the church, pagan mythology, with its sensuous allurements, began to afford subjects to the painter. As in the corresponding period in the history of Greek art, technical excellence was rapidly approaching its highest point, and increasing wealth and luxury multiplied the production of pictures for private purposes. The painter was no longer a public teacher of religion or morals, as in the days of Giotto or Orcagna; and as his public functions were superseded by his private ones, the art began to decline. Undoubtedly, however, the very perfection attained contributed materially to this result. Contemporary Florentine masters of this period were Fra Bartolommeo di San Marco and Andrea del Sarto, both of the highest excellence, and Michel Angelo Buonarroti, preëminent as painter, sculptor, and architect. The latter neglected illusive effects, despised oil painting, and aimed at the expression of life and power through action and movement; and the almost exclusive attention which he gave to the definition of form, the result doubtless of his cultivation of the three sister arts, made the development of physical qualities thenceforth the chief characteristic of the Florentine school. Of the daring heights to which he attained in his efforts toward grandeur of form and sublimity of expression, the frescoes of the Sistine chapel afford a memorable illustration; although here, side by side with his prophets and sibyls, looking "like beings to whom God has spoken and who have never since ceased meditating on the awful voice," are groups and single figures of such startling novelty of expression and action as to constitute a legacy of questionable value to the student of form. His influence was overwhelming in Florence, and almost every artist who came within its reach lost his individuality, and in attempting to follow him only debased and proved his own mediocrity. Some, however, were excellent painters, including Daniele di Volterra, celebrated for his "Descent from the Cross;" Vasari, the biographer of Italian

artists; Sebastian del Piombò; the Zuccari, and Angelo Bronzino. During the first quarter of the 16th century the grand climax of art was reached, and within that period the greatest painters of modern times flourished together, exercising in some sort a reciprocal influence, but each working out his own peculiar aims. Before the middle of the century a steady decline was discernible, not in Florence alone, but all over Italy, Venice perhaps excepted; and as the great masters one by one dropped off, they were succeeded by crowds of servile mannerists, who painted rapidly and carelessly to meet the increasing and not very discriminating demand for pictures, and whose works, even when devoted to sacred subjects, had in them "more of earth than of heaven." "We paint six pictures in a year," says Vasari, "while the earlier masters took six years to a picture;" a remark which his own practice strikingly illustrated. The latter part of the century, however, witnessed a fresh development in the Florentine school, and Ludovico Cardi, called Cigoli, introduced a new style, distinguished by careful drawing and brilliant coloring; but few names of note occur among his followers, except that of Carlo Dolce, a careful painter of female heads. Pietro di Cortona about the middle of the 17th century introduced a florid, ornamental style of fresco painting, the followers of which were called by the Italians the *machinisti*. Little can be said of Florentine painting after this.—Painting seems to have made little progress in Venice previous to the time of Giotto, and during the 14th century no works of any considerable importance were produced. The little island of Murano may be considered the nursery of Venetian art, and the Vivarini, a family of painters who lived there, its first exemplars. Commercial intercourse had familiarized them with the works of German and Flemish painters, the rich and vivid coloring of which was readily adopted by contemporary Venetian artists, although until near the middle of the 15th century they designed with an antique severity borrowed from their neighbors the Paduans. Giovanni and Gentile Bellini, sons of Jacopo Bellini, were the first great artists of the school, as they were among the first in Italy to substitute oil painting for distemper. With a tendency to elaborate finish, and a dry though correct manner, their works are distinguished by sweetness and purity of expression, and afford a foretaste of that rich coloring which subsequently became the chief characteristic of Venetian art, and which reflected the cheerful and festive spirit of the people. With the opening of the 16th century commenced a new epoch in the history of the school, and the genius of two scholars of the Bellini, Giorgione and Titian, created a style in which a bold and decided handling, and a "golden glow" of color, with great truthfulness of detail in landscape, draperies, and other accessories, were marked features. The former died early, but

Titian, who long survived his great contemporaries of the early part of the century, reached the summit of his art in history, landscape, and portraiture, and stamped the school of Venice as incontestably the first in color. Aside from portraiture, in which he had no rival, he was perhaps greatest in his representations of the naked female form. Among his imitators were Andrea Schiavone and Alessandro Bonvicino, called Il Moretto di Brescia. In the latter half of the century flourished 8 other painters scarcely less illustrious than Titian, viz., Jacopo Robusti, called Tintoretto, Paolo Cagliari, called Veronese, and Jacopo da Ponte, called Bassano; the first one of the most vigorous and rapid of painters, but unequal in his performances; the second a consummate master of color, delighting in scenes of festive pomp and splendor, with rich costumes and architecture; and the third the earliest and one of the best of the Italian painters of *genre*. The true Venetian style of these masters deteriorated in the hands of their successors, and the subsequent history of the school is unmarked by a single great name, though artists of merit were not uncommon.—Intimately connected with the history of the early Venetian school was that of Padua, to which a fresh impulse was given in the first half of the 15th century by Francesco Squarcione, whose collection of drawings and casts from the antique greatly promoted the cultivation of form, and influenced the art throughout northern Italy. Jacopo Bellini, of Venice, acquired there his peculiar dry manner; and Andrea Mantegna, the greatest painter that had appeared in the north of Italy up to the middle of the 15th century, was its most eminent pupil. The latter, distinguished for his severely classic and statuesque design, founded the Mantuan school, which produced many of the most famous painters of Lombardy.—The Roman school may be said to have sprung directly from the Umbrian, so called from the ancient district of Umbria, within the limits of which its artists practised their vocation. The region was secluded and the inhabitants remarkable for religious enthusiasm; whence perhaps the spiritual, almost ascetic, style of its early painters. The most distinguished among these were Piero Cavallini, Gentile da Fabriano (whose style Michel Angelo declared was like his name, *gentile*), and Piero della Francesca, after whom came Pietro Perugino (born in 1446, died in 1524), by far the best painter of his school up to his time, and whose style, though wanting in vigor, was distinguished by *maîtrise*, grace, and tenderness of expression. His scholars were numerous, including Pinturicchio, Andrea Luigi, called L'Ingegno, Lo Spagna, and above all Raphael (Raffaello Sanzio d'Urbino), whose fame has overshadowed the rest. Of the various excellences of this remarkable man, who, dying at the age of 37, left the greatest name by general consent in modern painting, it is unnecessary to speak at length here. He has been described as "the first of painters,

for moral force in allegory and history unrivalled; for fidelity in portrait unsurpassed; who has never been approached in propriety of invention, composition, or expression; who is almost without a rival in design; and in sublimity and grandeur inferior to Michel Angelo alone." In separate qualities he may have been equalled by some contemporary painters, and in color, which he regarded as a means and not an end in painting, he was inferior to the Venetians; but his frescoes in the Vatican, his Madonnas and holy families, his great altarpieces and his cartoons nevertheless represent the highest efforts of modern art, and have made his style not that of Rome alone, but of the world. Raphael had numerous scholars, who imitated him with more or less success, and some of whom assisted him in the execution of his frescoes. But after his death most of those who had original genius deviated into exaggerations and insipidities, and soon lost all traces of the noble grace and power of their master. The sack of Rome by the constable de Bourbon in 1527 caused the dispersion of his followers then in the city, who carried into all parts of Italy a spurious style, miscalled the "Raphaelesque." His best scholars were Giulio Romano, the most distinguished of all for original power, but of a far lower order of mind than his master; Gian Francesco Penni, called *Il Fattore*; Perino del Vaga; Giovanni da Udine; Polidoro da Caravaggio; Pellegrino da Modena; Bartolommeo Ramenghi, called *Il Baginacavallo*; and Benvenuto Tisi, called *Il Garofalo*. Primaticcio, Nicolo del Abate, and Tibaldi also acquired the Roman style of Raphael, which they carried into France and Spain. The execution by Michel Angelo of the "Last Judgment" in the Sistine chapel in 1541 produced a crowd of feeble imitators of his style, after whom came Giuseppe Cesari d'Arpino and Michel Angelo Caravaggio, the former representing the *machinisti* and the latter the *tenebrosi* or *naturalisti*, whose style, though not deficient in power, was founded on mere natural imitation, and was characterized by coarseness and vulgarity. These were succeeded by the Carracci and their followers, who flourished during the 17th century; and in the 18th the history of the art closes with Andrea Sacchi, Carlo Maratti, and Raphael Mengs, the first a painter of merit, the last two academic and mannered.—The Bolognese school, though claiming to share with those of Tuscany, Rome, and Venice the honor of bringing about the revival of painting, presents no name of great importance until the close of the 15th century, when Francesco Francia, a painter of genuine religious sentiment, and the friend of Raphael, flourished. His influence was only temporary, and it was not until about 1585 that the school witnessed its most brilliant epoch in the establishment by Ludovico, Agostino, and Annibale Carracci of their celebrated academy, called, from the principles on which it was conducted, the eclectic school of Bologna, and the funda-

mental idea of which was to combine the closest study of nature with the imitation of the best qualities of the old masters. The Carracci and their chief scholars, Domenichino, Guido Reni, Lanfranco, Albani, and Guercino, extended their influence throughout Italy; but their efforts tended to substitute academic tame-ness for what little originality survived the decline of painting, and their style, though frequently admirable as illustrated by themselves, did not long survive them. Their greatest merit perhaps consisted in the attention they gave to landscape.—Of the schools of northern Italy, in addition to those mentioned, the most noted was that of Parma, the great ornament of which was Antonio Allegri, known as Correggio, who in the early part of the 16th century brought the art of chiaroscuro and relief to perfection. One of his chief characteristics was a winning softness and grace, tending in some instances toward affectation; and the evil consequences of this tendency are visible in the works of Francesco Mazzola, called *Il Parmigiano*, otherwise an excellent painter, and after Correggio the best artist of the school.—At Milan a flourishing school was established by Leonardo da Vinci, who executed there some of his finest works. About the commencement of the 17th century the Procaccini founded an eclectic school in Milan.—The school of Naples claims an antiquity equal to that of Florence, but no name of importance occurs until the 17th century, when Giuseppe Ribera, called *Lo Spagnoletto*, and Salvator Rosa, both leading painters of the *naturalisti*, flourished. The latter was one of the earliest and most vigorous of landscape painters, but even in this class of works reflects the coarse feeling of his school. The last Neapolitan painter of eminence was Luca Giordano, called, from his rapidity of execution, *Fa Presto*.—Although painting in Germany can be traced back to the Carolingian period, little is known of the productions of its artists, the missal illuminators excepted, previous to the 13th century. During the latter half of the 14th century, under Meister Wilhelm, or William of Cologne, who, according to a contemporary chronicler, was "the best painter in all German lands, and painted all sorts of men as if they were alive," the school of Cologne acquired considerable repute. The pictures in Cologne attributed to this master and to his scholar, Meister Stephan, notwithstanding a Gothic hardness peculiar to all mediæval German art, are remarkable for richness of coloring, careful finish, and deep religious sentiment. Contemporary schools flourished in Nuremberg and Westphalia. The 16th century witnessed the culmination of German art in the person of Albrecht Dürer, the scholar of Michael Wohlgemuth of Nuremberg, and almost equally distinguished as painter, sculptor, and engraver, though now chiefly known in the last capacity. Lucas Cranach about the same time headed the contemporary school of Saxony, and enjoyed almost as great a reputation as Dürer

himself. Other painters of the period were Albrecht Altdorfer, a scholar of Dürer, Matthias Grunewald, Hans Burgkmair, and particularly Hans Holbein the younger, in whom the old mediæval ecclesiastical spirit is relieved by freer conceptions of nature and a purer sense of physical beauty, while the characteristic German style is retained. After 1527 his history belongs to England. Subsequently the Germans became imitators of the Netherlandish and Italian eclectic schools, and previous to the 19th century few names of note occur among them. In the first decade of the present century a remarkable revival was commenced by a number of young German painters assembled in Rome, the leading motive of which was a protest against the effete academic generalization under which art languished. The result was the formation of a mystical school, which, under the lead of Overbeck, has attempted to revive the sentimental, ascetic art of the 14th century; and of another more purely Teutonic, whose leaders, Cornelius, Kaulbach, Hess, and Schnorr, have idealized history with considerable success. Lessing, Bendemann, and others instituted a reaction against the severe ecclesiasticism of Overbeck, and formed a separate school, the chief seat of which is Düsseldorf. Accounts of these movements and of their instigators will be found among the biographical articles of this work.—The Flemish school dates from the commencement of the 15th century, when Hubert and Jan van Eyck established themselves at Bruges, and drew around them pupils from all parts of northern Europe. Dignity and strength, combined with a close imitation of external nature, were the characteristics of their style, as illustrated in the celebrated polypptych painted by them for the church of St. Bavon, Ghent. This work presents also some of the first successful attempts at landscape painting. To Hubert Van Eyck is due the discovery, not of oil painting, which was practised with more or less skill for 2 or 3 centuries before his time, but of a drying varnish, which was at the same time more suitable for mixing with pigments than any vehicle previously known. The new method was adopted by northern artists generally in the first half of the 15th century, and was about 1450 carried into Italy by Antonello da Messina. Among the scholars and successors of the Van Eycks were Roger of Bruges, Hans Hemling or Memling, perhaps the best painter of the school, and Jan Mabuse. A contemporary school flourished at Antwerp, which previous to the middle of the 16th century produced at least two first-rate artists, Quentin Matsys and Lucas van Leyden, to whom succeeded a crowd of imitators of the Italians, whose efforts in design were worthless, but who transplanted into the Netherlands the true Venetian coloring. With the 17th century commenced the most brilliant epoch of the Flemish school, during which the genius of Peter Paul Rubens, whom Haydon charac-

terizes as "a giant of execution and brute violence of brush, and brilliant color and daring composition," revived the old glories of Florence and Venice. Physical energy and life were his characteristics, and these were reflected with exaggerated coarseness in the works of Jordaens, Gaspar de Crayer, and others of his followers, who form what is known as the school of Brabant. Anthony Vandýke, his most illustrious scholar, however, painted with more elegance than his master, and brought portraiture to the highest excellence. Painting languished in the Netherlands after the latter part of the 17th century, but, as in other parts of Europe, has within the present century experienced a revival, which will be productive of good results. The art is now pursued with success by Wappers, De Kaiser, Gallait, Verboeckhoven, and other Belgian artists. Gallait especially ranks among the first of living historical painters.—The Dutch school seems to have been identical with the Flemish until the early part of the 17th century, when a peculiar reaction from the mannered style of the masters of the preceding century manifested itself in Holland. This movement was headed by Paul Rembrandt van Ryn, a man of singular genius, who took up a hostile position against the study of the ideal, and deliberately proceeded on the principle of imitating vulgar nature. The ugliness of his models, selected apparently to show what obstacles he could overcome, is however more than redeemed by surpassing effects of light and shade, and through his mean and coarse design shines the individuality of a gloomy and original mind. His style, called by Kugler the "phantasmagoric," was the very opposite of that of Rubens, and in landscape and history severed the Dutch school completely from that of Brabant. Rembrandt had some eminent scholars, including N. van Bergen, Eeckhout, P. de Koninck, F. Bol, and Nicolas Maas. Contemporary with Rembrandt flourished a class of painters of remarkable merit as colorists, and well versed in the technics of their art, who cultivated what is called *genre*, and so greatly excelled in this department as to justify the remark, that "*genre* and the Dutch style are almost synonymous." Their pictures are generally of small size, and are characterized by minute and exact imitations of familiar and frequently of vulgar subjects. Among the most eminent of these, of whom we can only give the names here, were Peter Breughel and his sons Hell Breughel, so called from the diabolical character of his subjects, and Velvet Breughel, famous for his soft handling; David Teniers, the elder and the younger, the latter a distinguished painter of low life; Adrian van Ostade, Adrian Brauwer, and Jan Steen, equally celebrated in the same department; Gerard Terburg, Gerard Douw, Gabriel Metz, and Franciscus Mieris, eminent painters of genteel life. About the same time landscape painting became developed among the Dutch with wonderful rapidity, and generally with a

purser taste than *genre*. Paul Bril caught the Italian spirit from painting in Italy, and Jan and Andreas Both, Pynaeker, Albert Cuyp, Nicolas Berghem, Jan Miel, Karel Dujardin, and Adrian van der Velde cultivated an ideal or pastoral style with eminent success. Jacob Ruysdael, Minderhout Hobbema, and Antony Waterloo excelled in vivid and natural imitations of native scenery, without aiming at ideal beauty; William van der Velde the younger and L. Backhuysen in marine views; Philip Wouvermans in hunting parties; and Paul Potter in landscapes with cattle and figures. Snyders, the friend of Rubens, and the greatest of all the animal painters, may be mentioned here; also Hondekoeter, a painter of poultry; and De Heem, Rachel Ruysch, and Van Huysum, celebrated for their fruit and flower pieces. A few of these lived into the 18th century, but before that time the art had lost most of its vitality.—The Spanish school stands almost alone in the history of art in the uniformly religious and ascetic character of its productions. A rigid code of rules, established by ecclesiastical authority, prescribed the method of treatment when sacred subjects were selected, and the strong Catholic feeling of the artists led them to give an almost exclusive attention to this class of subjects. Painting can scarcely be said to have had an existence in the Spanish peninsula previous to the middle of the 15th century, and it was not until the 17th that the school had any other than a local reputation. The visit of some Flemish artists in the 15th century, and somewhat later of Titian and other Italian masters, gave the native painters their first practical ideas of color and design. In the 16th century schools were already established in Castile, Valencia, Seville, and elsewhere, that of Seville being perhaps the most distinguished. Among the eminent painters connected with them were Antonio del Rincon, Luis de Vargas, Luis de Morales, Vincente Joanes, sometimes called the Spanish Raphael, Pablo de Cespedes, and Juan de las Roelas, most of whom studied in Italy, and flourished in the 16th century; Francisco Pacheco; Alonso Cano, eminent as sculptor, painter, and architect; Francisco Zurbaran, a distinguished painter of the naturalistic school of Caravaggio; and Diego Velasquez de Silva and Bartolomé Esteban Murillo, who share the honor of making Spanish art known and admired in all parts of the civilized world. The characteristics of their styles are described in the biographical notices of them. Since the commencement of the 18th century Spain has produced no painters of eminence.—Painting was practised in France as early as the time of Charlemagne, but nothing like a national school can be said to have had an existence until after the visit of Primaticcio and other Italian artists, at the invitation of Francis I. Simon Vouet, who flourished at the commencement of the 17th century, received an Italian education, and is considered the master and model of the suc-

ceeding generation of French painters. Contemporary with him were Nicolas Poussin, eminent for the classic spirit of his compositions and his landscapes; Gaspar Poussin, also eminent in landscape; Claude Gellée, a master of aerial perspective, as of nearly every other branch of landscape painting; and Sébastien Bourdon. All of these, though French by birth, practised their art and passed most of their lives in Italy. Eustache Le Sueur and Charles Le Brun were the most eminent of Vouet's scholars, the latter, an artist of merit despite his affectation of manner and violations of taste, being the painter of many of the immense pictures at Versailles which testify to the vanity and extravagance of Louis XIV. In the succeeding reign Antoine Watteau painted *fêtes galantes* with grace and effect; Joseph Vernet was noted as a marine painter; and somewhat later Jean Baptiste Greuze obtained a unique reputation for his female heads and charming representations of domestic life. Painting steadily deteriorated during the latter half of the 18th century, until restored to a temporary vitality about the time of the French revolution by Jacques Louis David, whose style, known as the "classic," though dry, pedantic, and deficient in true expression, showed considerable mastery of form, and was followed by Guérin, Drouais, and a numerous band of scholars. Gros first broke away from this "morbid imitation of the antique," as it has been called, and with Géricault and others inaugurated the system of painting from nature, whence originated the modern French school, the most distinguished ornaments of which are Leopold Robert; Paul Delaroche, one of the chief painters of history of the present century; Ary Scheffer, singularly pure and severe in his ideal conceptions; Horace Vernet, unrivalled in battle pieces; Delacroix, Ingres, and Couture; Rosa Bonheur, whose horses and cattle are among the best ever painted; Troyon, excellent in landscape; and Edouard Frère, Chavet, and Meissonier, eminent in different departments of *genre*.—Of painting in England little can be said previous to the 18th century. Jan Mabuse, Holbein, Sir Anthony More, Rubens, Vandyke, Lely, Kneller, and other continental painters, had during the two previous centuries successively practised their art there, principally in the department of portraiture; but their influence was unavailing to form a national school. The few native artists of note who flourished within this period, including Hilliard, Isaac and Peter Oliver, miniature painters, and Dobson, Nicholas Stone, and Jameson, called the "Scottish Vandyke," were portrait painters, and that branch of painting alone received encouragement. The first important historical works by an English artist were the frescoes executed by Sir James Thornhill in the interior of the dome of St. Paul's, London; but his illustrious son-in-law, William Hogarth, the great satirical painter of his time, and one of the most original painters of any age, is the

first name of note in the history of British art. He had however but little direct influence upon the artists of his time, and the honor of founding the modern English school belongs to Sir Joshua Reynolds, excellent in portraiture and history, and preëminent as a colorist. His contemporary and rival, Thomas Gainsborough, often equalled him in portraits, but is better known as the first of a line of landscape painters whose works would adorn the art of any epoch. Among other painters who flourished during the latter half of the last century were Richard Wilson, eminent in landscape; Barry, Opie, Northcote, Fuseli, Copley, and West, historical and portrait painters, the last two being natives of America. The influence of Reynolds upon the succeeding generation of painters is shown in the strong bias for color which now forms one of the chief characteristics of the English school. In the first quarter of the present century flourished Sir Thomas Lawrence, Hoppner, Raeburn, and Jackson, portrait painters; Wilkie, the best painter of low life England has produced; Haydon, a historical painter of genius, in spite of his mannerism and egotism; Etty, a vigorous colorist; Turner, the most original and imaginative, perhaps, of landscape painters; Constable, Calcott, W. Collins, Morland, Nasmyth, Bonington, eminent in the same department; and John Martin, whose architectural extravagances and exaggerated effects of light and shade had a brief popularity. During the same period *genre* was cultivated by Bird, Smirke, Stothard, and many others, and has been continued to the present day by Newton, Leslie, Cooper, Mulready, MacIise, Eastlake, Redgrave, E. M. Ward, Webster, Hamilton, Cope, Dyce, C. Landseer, J. R. Herbert, Horsley, W. J. Muller, Frith, Faed, and many others, most of whom have also painted history and landscape with success. Among prominent landscape painters of the present day are Oreswick, Stanfield, D. Roberts, James Ward, Linnell, and F. Lee. Sir Edwin Landseer occupies a peculiar and prominent position as a painter of dogs and animals of the chase. The British school of water color painting, founded by Paul Sandby in the middle of the last century, is the best in the world, and in the department of landscape has produced works scarcely inferior to those of the oil painters. Among its chief artists are Turner, Prout, Copley, Fielding, Roberts, W. Hunt, Lewis, Cattermole, Cox, Absolon, Corbould, Nash, and Stanfield. Within the present century has arisen a peculiar school, styling itself the "Pre-Raphaelite Brotherhood," and represented by William Holman Hunt, Millais, Dante Gabriel Rossetti, and some others, who, according to their most earnest advocate, Ruskin, "oppose themselves to the modern system of teaching, and paint nature as it is around them, with the help of modern science, and with the earnestness of the men of the 18th and 14th centuries."—For information concerning the chief depositories of paintings in Europe,

the reader is referred to the article *MUSEUM*.—Painting made little progress in the United States previous to the present century. Benjamin West, a native of Pennsylvania, and the second president of the British royal academy, gained all his reputation abroad; and Copley, though he left many admirable portraits in America, established himself in England before the revolution, and produced his most important works in history and portraiture in that country. Charles Wilson Peale and Col. John Trumbull were the first native artists of note who practised their art to any considerable extent at home; and the Trumbull gallery of portraits and pictures illustrating American history, at New Haven, would be a valuable contribution to the art of any nation. In the early part of the present century Malbone, Gilbert Stuart, and Allston vindicated the claim of America to the possession of the highest order of artistic ability; the first an excellent miniature painter, the second a rival of Reynolds in portraiture, and the third an imaginative painter of high excellence in all walks of his art. About the same time John W. Jarvis and Thomas Sully held a high rank as portrait painters, Vanderlyn painted history with success, and somewhat later Newton and Leslie, Americans by birth or parentage, established themselves in England and became celebrated in the modern English school of *genre*. About 1825 Thomas Cole founded what may be called the American school of landscape painting, a department which was thenceforth cultivated by native artists more universally than any other. The works of Cole, though not remarkable as literal transcripts of individual forms, are characterized by a thoughtful morality, and a tendency to allegory. The series of "The Course of Empire" and "The Voyage of Life" are among the finest specimens of American art. Contemporary with Cole or immediately succeeding him were Doughty, Durand, Inman, and Fisher, the two first named eminent in landscape, and the third the first American painter who attempted *genre* with success; Rembrandt Peale, Weir, Huntington, Rothermel, and Page, painters of history, landscape, and *genre*, and the last named distinguished as a colorist; Neagle, Morse, Ingham, Harding, and Fraser, portrait painters. Since the middle of the century landscape painting has received an active and healthful impulse, and no artists in any European school show more talent in this department than those of America. Prominent among the latter are Church, Kensett, G. L. Brown, Cropsey, Chapman, Casilear, W. and J. M. Hart, Mignot, Gignoux, Gifford, Colman, Cranch, Gay, Inness, Shattuck, Hubbard, Boughton, Dana, and many others, including some mentioned above. The works of all of these are characterized by close imitation of nature, and in general by a freedom from old world conventionalisms. Within the same period *genre* has been cultivated with considerable success

by Mount, Lang, Lambdin, May, Ehninger, Darley, Hoppin, Blauvelt, Eastman Johnson, William Hunt, Edmonds, and others; and portrait painting by Healy, Elliott, Hicks, Baker, Stone, and Staigg, the last also a miniaturist. Hays, Tait, Beard, and Hinckley are well known animal painters. History has comparatively fewer followers, and that department receives less encouragement than either of the preceding. There are however some prominent painters of this class, including Leutze, a pupil of the Düsseldorf school, Gray, Powell, Rossiter, Terry, and White.

PAINTS, coloring substances variously prepared, so that they may be spread with a brush over surfaces of wood, paper, canvas, &c. The name may properly include water colors, which are mixtures of the coloring matters with water and gum, usually prepared in the form of solid cakes, and which when wetted with water and rubbed readily impart to it a portion of the coloring matter. It may also include the colors used by artists, and those preparations employed in house painting. The former are distinguished as artists' or oil painters' colors, and the latter are known as the common paints. The sources of the colors of the last two classes are to a considerable extent the same, but artists' colors are more various and in general much the more carefully prepared. The secret of their perfection consists in the most thorough levigation and grinding by long continued rubbing between hard surfaces. By this means their lustre and transparency are most effectually increased. We can only give a very general description of the principal colors employed by artists.—

Whites. Flake white is a preparation of ceruse or carbonate of the oxide of lead with excess of the oxide. (See **WHITE LEAD**.) Silver white (*blanc d'argent*) or krems white is the same preparation from selected scales of the purest and whitest ceruse, ground for an unusually long time with particular care. These have been regarded as the best white for oil or resin vehicles, when pure; but they are often adulterated with pipe clay, sulphate of barytes, chalk, and other substances, the first two of which may be detected by their insolubility in dilute nitric or acetic acid; and they are acted on and tarnished by the impure gases common in the atmosphere of dwellings, particularly those lighted by gas. They are consequently rapidly giving place to the zinc white, the purest variety of which, known as snow white (*blanc de neige*), possesses the good without the objectionable qualities of the flake white. (See **ZINC**.) Venice white is prepared from equal parts of ceruse and sulphate of barytes. For a dense ground the preparation known as Pattinson's oxichloride of lead is advantageously used.—**Yellows** derived from vegetable sources, as gamboge, are not durable, bleaching in the light. A durable yellow of pale canary color is obtained from chromate of strontian, which is produced by adding a

solution of chloride of strontian to one of chromate of potash. Sulphuret of cadmium forms a rich and brilliant orange, also permanent. The oxides of iron, in the native ochres or the artificial preparations, furnish a variety of shades of yellow, as well as of red, which are among the most durable and valuable paints. The native ochres properly levigated and ground produce such a variety of beautiful colors, that there is little inducement to have recourse to artificial preparations of this description. A great variety of mineral yellows might be named which possess a good color and are more or less used, but are not durable, are affected by foul air, and moreover often injuriously affect other colors with which they come in contact. Such are the chrome yellow and chrome orange, preparations of chromic acid and lead. Naples yellow, a compound of unknown composition, but said to contain the oxides of lead and antimony, and according to some of arsenic also, is a yellow of much reputation, but is readily tarnished by foul gases, by the light, and even by contact with an iron or steel spatula.—**Reds.** Vegetable substances, as the madders, afford, when made into lakes with earthy bases, rich and beautiful colors; but, like most vegetable colors, they cannot be depended upon for permanency. The more highly oxidized ochres produce very valuable reds, such as the light red and Indian red. Venetian red is an inferior sort of the same class, and the same may be said of colcothar. Vermilion red is a preparation of the bisulphuret of mercury. (See **CINNABAR**, and **MERCURY**.) This is a beautiful color, and not affected by any of the ordinary elements of change—acids or alkalis. The native cinnabar is much inferior to the artificial. Other preparations of mercury, as the peroxide (red precipitate) and the iodide, also produce red colors, but they are not durable, and consequently are little esteemed. Red lead and phosphate of cobalt become dark when mixed with oil. The ammonio-perchloride of palladium is a rich, deep, and beautiful color. Carmine and the other lakes (see **CARMINES**, and **LAKES**) are very rich reds, but better adapted for miniature painting and water colors than for oils. Rouge is a carmine preparation.—**Blues.** The only really good blues are those known as ultramarine, the native or artificial. (See **LAPIS LAZULI**, and **ULTRAMARINE**.) These are brilliant colors of a purplish hue, not affected by foul gases, but removable by acids. That prepared by Zuber of Alsace, having less of the purple, was highly approved in the exhibition of 1851, and particularly recommended for the aerial tints in landscape painting. The preparations of cobalt, including smalt blues, are feeble colors. Silicates of copper, permanent enough in enamels, as in the tiles from Nineveh of 4,000 years' standing, soon blacken when broken up and mixed with oils. All the so called vitreous or silicious preparations, when levigated for pigments, are liable to change just as the sub-

stances change of which they are composed. Prussian blue is not a permanent color, and cannot be mixed with colors containing any alkali. The indigo blues fade in the light.—

Greens. Oxide of chromium, prepared by igniting the orange-colored chromate of mercury, furnishes the chromium green, an opaque light green, of a full body, and permanent. Emeralds owe their color to this oxide. The mineral green-earth affords a delicate neutral green, known as *terre verte*, which is quite permanent, though attackable by acids. Various salts of copper, as the carbonates, phosphates, acetates (verdigris), disulphates, and arsenites, as Scheele's green and Schweinfurt's (see **GREEN**), produce greens of different shades; but all are acted on by foul gases and blackened by oil. Nickel green also has the latter defect. Rinman's green, derived from zinc or cobalt, is permanent, but has not the body or the fine color of chromium green. The greens derived from the artificial ultramarine process are similarly defective, and they too are permanent.—

Browns. These, being in chief part prepared from vegetable matters, readily change and fade, and are among the least permanent colors. Umber, a natural mixture of a brown oxide of iron, manganese, and clay, found in the island of Cyprus, is a very useful color either in its natural state or burnt. The *terre verte* when burnt produces a beautiful brown. The color is also prepared from asphaltum, either the natural product or the residue in the distillation of the coal oils. A variety of browns, some of them rich, deep, and transparent, are prepared from decomposed vegetable matters, as peat, mixed with bituminous substances. Burnt ivory and bones give brown colors not so permanent as the blacks obtained from the same materials. Mummy brown is a preparation of white pitch and myrrh combined with animal matter. Prussian brown is obtained of various tints by calcining over an open fire in an iron spoon at a full red heat good Prussian blue, not of English manufacture. When carefully prepared from a good blue, the bits on being broken appear in part of blackish and in part of yellowish brown hues. A uniform tint is secured by grinding the products. Several trials may be necessary to obtain just the shade of brown desired. The color spreads remarkably well, is very permanent, and dries more rapidly than any other of the transparent colors. Sienna is an ochre of deep yellow brown, and by calcining is converted into a reddish orange brown.—**Blacks.** These in general are prepared by burning organic substances in close vessels and collecting the black carbonaceous residues. Lampblack is the soot of resins, fats, and oils; bone black, the residue from the calcination of bones. A durable bluish black is obtained from the calcination of vine twigs. The mineral peroxide of manganese affords a black possessing good drying properties.—The paints in common use for house painting, for the purpose of protecting or ornament-

ing the woodwork they cover, consist chiefly of a basis of white lead, white zinc, or a mixture of these with sulphate of barytes (see **WHITE LEAD**, and **ZINC**), which is either used as a white pigment, or is colored by the introduction of suitable coloring matters, called **stainers**. These consist of the colors above named, and their proportion rarely exceeds $\frac{1}{2}$ of the mixture. To prepare the compound for use, the white lead and stainers are ground in a mill with oil, usually linseed, and for outdoor work especially this is first boiled, by which its drying quality is increased, and it is made thicker. It was formerly the practice for the painters to do their own grinding by hand upon a stone table with a stone muller; but the work is now more economically done by the manufacturer, or in mills especially appropriated to this purpose. In such establishments close mills are provided in which noxious materials, as white lead, red lead, the mercurial compounds, &c., are ground without endangering the health of the workmen, as always occurred in the ordinary methods of grinding by their dust escaping into the atmosphere. Other substances used as dryers beside boiled oil are litharge, sugar of lead, and spirits of turpentine. In the application of paints the process is varied according to the nature of the surface to be covered, and the effect required. For the best work the first coat of paint is of thin consistency in order that the pores of the wood or plaster may be filled with the oil, which it absorbs from the paint. Its drying is hastened by the addition of litharge. A second coat of thin paint may advantageously be added when the first has dried. To this succeeds a third and thicker coat, containing some spirits of turpentine and some of the coloring pigment. Upon this is laid a fourth coat thick and heavy; mixed with equal parts of oil and spirits of turpentine, and made rather darker than the shade required. For this coat sugar of lead is a good dryer. Within two days, and before this coat has become quite dry, the finishing or flattening coat may be applied. This is of pure white lead diluted with spirits of turpentine only, and colored a few shades lighter than the pattern. Gold size of the japanners is used in small quantity as the dryer. This coat dries as rapidly as it is laid on, and, incorporating itself with the heavy coat beneath, gives to the surface a beautiful gloss and finished appearance. Before putting the first coat upon woodwork, the surface is carefully smoothed and prepared for it; and before applying a new coat the surface already covered is rubbed with sand paper. Painting in imitation of oak, walnut, rosewood, &c., is called **graining**, this imitation of the grain of the wood being brought out upon the groundwork of 4 or 5 coats, which is left of the general color of the wood to be imitated. The last coat is mixed with equal parts of oil and spirits of turpentine. The colors are ground in water and mixed with beer, which gives them sufficient tenacity. The marks imi-

tating the grain of the wood are made by drawing irregularly over the surface an instrument made like a comb, its teeth producing the parallel sets of lines. The finishing coat is of copal varnish.

PAISIELLO, GIOVANNI, an Italian composer, born in Taranto, May 9, 1741, died in Naples, June 5, 1816. He was educated in the conservatory of St. Onofrio at Naples under Durante, and at the age of 20 was a prolific composer of masses, psalms, motets, &c. His first opera was produced in 1768 at Bologna, and during the next 18 years he is said to have composed upward of 50 for the chief cities of Italy. Most of these, however, speedily sunk into oblivion. In 1776 he accepted an invitation from Catharine II. to establish himself in St. Petersburg, where he remained 9 years, producing in the interval several operas and oratorios, and a variety of miscellaneous pieces of vocal and instrumental music. Proceeding from St. Petersburg to Vienna, he composed for the emperor Joseph II. 12 symphonies, and the opera *Il re Teodoro*, which affords the first instance of the use of the finale in this class of compositions. On his return to Naples he was appointed royal chapelmaster with a large salary, and for many years remained in that city, declining invitations from the king of Prussia and the empress Catharine, but writing an occasional opera for London and other cities. During the temporary overthrow of the Bourbons in 1799 he accepted the office of national director of music under the republic, for which he remained in disgrace for several years after the return of the royal family. In compliance with pressing invitations from Napoleon, he visited Paris, where, as chapelmaster to the first consul, he produced a number of masses, motets, and other compositions. Returning to Naples in 1804, he was restored to his office of royal chapelmaster, in which he was continued by Joseph Bonaparte upon assuming the crown, and subsequently by Murat. Paisiello's industry and facility are shown in the number and variety of his works, which comprise 27 grand and 51 buffo operas, 8 interludes, and a vast collection of cantatas, oratorios, masses, and the ordinary forms of instrumental music. His operas, now scarcely known, rank among the choicest musical works of the last century, and were once universally sung and admired in all parts of Europe. His qualities have been said to consist of "fertility of invention; an extraordinary and happy facility of finding subjects full both of nature and originality; a talent unique in developing them by the resources of melody, and embellishing them by interesting details; an arrangement always full of fancy and learning; and a taste, grace, and freshness of melody by which he has far surpassed most other composers, and has been a model to those who have labored after him."

PAISLEY, a parliamentary and municipal borough and manufacturing town of Renfrew-

shire, Scotland, situated on both banks of the White Cart, about 8 m. above the junction of that river with the Clyde, 8 m. W. by S. from Glasgow; pop. in 1851, 47,952. The most interesting of its public buildings is the nave of an old abbey church, now used as a parish church. The abbey of which this is the only relic was the family burial place of the high stewards of Scotland before their accession to the throne. The navigation of the Cart to Paisley was improved at the instance of the municipal corporation in 1787, and vessels of 180 tons burden can now go up to the town. Paisley has communication with Glasgow by canal, and with all parts of the kingdom by the Glasgow and Paisley railway. The manufacture of shawls, which was introduced about the beginning of the 19th century, is the most important branch of industry. Silk, cotton, woollen, and mixed fabrics are made in close imitation of those of India, and shawls of genuine Cashmere wool are woven equal in texture and far superior in beauty of design to those of the East. Silk gauze has long been one of the chief staples, and there are also large establishments for the manufacture of muslins, plaids, chenille, handkerchiefs, cotton, thread, carpets, soap, leather, malt and distilled liquors, &c., beside bleacheries, brass founderies, boat-building yards, and a large silk-throwing mill.—In the time of Agricola the Romans had a station upon the present site of Paisley; but the town owes its existence to the priory, founded in 1160, on the E. bank of the Cart, by Walter, high steward of Scotland. In 1219 the priory was raised to an abbacy by Pope Honorius. With the growth of this establishment arose Paisley, first a small town on the opposite bank of the river from the abbey, and almost a dependence of it; and in 1488 it was erected by James IV. into a free burgh of barony.

PAIXHANS, HENRI JOSEPH, a French general and inventor, born in Metz, department of Moselle, Jan. 22, 1783, died at Jouy-aux-Arches, near Metz, Aug. 19, 1854. He was educated at the polytechnic school, and entering the artillery rose to the rank of general. He was also a member of the chamber of deputies, where he occasionally spoke on naval and military affairs. As an inventor he is well known by the guns and projectiles which bear his name, and which were first employed in France in 1824. The guns, which were originally between 9 and 10 feet in length and weighed 75 cwt., were especially adapted for the projection of hollow shot and shells of a cylindro-conical shape. The latter, striking a ship with more exactness and force than the ordinary cylindrical projectiles, produce an explosion similar to the springing of a mine, and correspondingly destructive. In connection with his inventions Gen. Paixhans made numerous useful suggestions to the French government respecting the armament of ships of war or fortresses for the defence of the sea coast, which are embodied in a series of works

published between 1815 and 1849. (See *ARTILLERY*, and *NAVY*.)

PAJON, CLAUDE, a French Protestant theologian, born in Romorantin in Orléanais in 1626, died Sept. 27, 1685. He was educated at the academy of Saumur, where he studied theology under Amyraut, and at the age of 24 became preacher in Marchenoir. Although not prominent as a literary man, Pajon's abilities had become well known, and in 1666 he was made professor of theology in Saumur in place of Amyraut, who had died 2 years before. Already some of his doctrinal views had awakened attention, and though he was confirmed in his office by the provincial synod of Anjou, his teachings at Saumur gave great offence. He soon gave up the position of his own accord, and became a preacher in Orleans, where in 1678 he wrote an answer to Nicole's work entitled *Préjugés légitimes contre les Calvinistes*. His peculiar opinions now began to be spread not only by his own direct influence, but by the mouths of many zealous disciples. So much attention did the reputation of his Pelagian-Arminian views excite, that in 1676 Pajon suggested a trial of his teachings, which however resulted in nothing. After much controversy, several of the provincial synods in 1677 adopted measures to free the church from those entertaining his sentiments, although Pajon and his friends strenuously asserted that their doctrines were far removed from Pelagianism. He however did effective service for his church in his remarks on the pastoral charge issued by the Catholic clergy in 1682. His reply appeared in 1685. Soon after he died, grieving that his church would not receive the truth. His peculiar views were called Pajonism, although his followers would appear to have been more heterodox than himself.

PAJOU, AUGUSTIN, a French sculptor, born in Paris in 1780, died there, May 8, 1809. He passed 12 years as a government pensioner at Rome, and upon returning to France in 1760 established himself in Paris, where he passed the remainder of his life. He executed upward of 200 works in stone, metal, and wood, and for many years held the office of professor of sculpture in the French academy. He was also a member of the institute. Among his principal productions were Love as the ruler of the elements, in lead; Pluto holding Cerberus chained, which gained him admission to the academy; Psyche abandoned; statues of Pascal, Turenne, Bossuet, Buffon, and Descartes; and the sculptures of the façade of the Palais Royal. His works are designed in a natural style, and show a considerable improvement upon the productions of preceding French sculptors.

PAKINGTON, SIR JOHN SOMERSET, an English statesman, born Feb. 19, 1799. He is the son of William Russell, of Powick court, Worcestershire, and assumed the name of Pakington subsequent to the decease of his maternal

uncle, Sir John Pakington. In 1846 he was created a baronet. He entered public life in 1837 as member of parliament from Droitwich, which constituency he has represented down to the present time, and in politics is a conservative, and a conspicuous member of his party. He entered the Derby cabinet in 1852 as colonial secretary, and in the second Derby ministry, 1858-'9, was first lord of the admiralty. In the latter capacity he adopted measures for the improvement and extension of the British navy, the general features of which were retained by his successor in office.

PALACKY, FRANTISEK, a Bohemian philologist, critic, and historian, born in Hodslawitz, Moravia, June 14, 1798. He received a literary education under the care of his father, and completed his studies at Presburg and Vienna, devoting himself especially to the study of languages. Having in early life become acquainted with the celebrated Panalavist Kollar, he ardently embraced his views and devoted himself to the development of the Bohemian language and literature. In 1823 he repaired to Prague, where he was patronized by Count Sternberg, the founder of the national museum, and subsequently was appointed editor of the journal of that institution, the *Casopis českého Museum*, an office which he held for 10 years (1827-'37). In 1829 he was charged by the estates of Bohemia with the task of writing a critical history of his country, receiving at the same time the title of national historiographer and a pension for life. His appointment was not sanctioned by the Austrian government until after the accession of the emperor Ferdinand (1835). The first volume of Palacky's "History of Bohemia" appeared, at the expense of the estates, in 1836, in the German language, in which he had previously published a "Theory of the Beautiful" and a "History of Æsthetics," and in which he subsequently also described his "Literary Journey to Italy in 1837," undertaken in search of materials for his great historical work. While this was slowly progressing he also published the *Archiv český* (3 vols., 1840-'44), and the "Oldest Memorials of the Bohemian Language," the latter in German. The movements of 1848 opened to Palacky the field of political activity. He was elected president of the Slavic congress, which assembled in Prague in June; and after its speedy dissolution, and the suppression of the national movement in that city, he was sent as representative to the Austrian diet, in which he became the leader of the Slavic element. After the end of the revolution in Austria, which was hastened by this untimely Panalavist agitation, Palacky returned to literary occupations. In 1860, after the political revival in Hungary, he renewed with his friends the national Bohemian movement, though now as an ally of the Hungarians.

PALADIN (Lat. *palatinus*, from *palatium*, a palace; It. *paladino*; Fr. and Sp. *paladin*), originally an officer of the palace in the Byzan-

tine court, who ranked among the chief dignitaries of the empire. In the French romances of the middle ages the paladin, or *palasin* as he was at first called, was a knight of great strength and bravery, whose loyalty to his sovereign was only equalled by his chivalric bearing and generosity. The favorite types of this character are Roland, Oliver, Rinaldo, and the other paladins of the court of Charlemagne, whose exploits have been celebrated by Boiardo, Ariosto, and other Italian poets, and in innumerable legends and ballads. The term has been poetically applied to the knights of King Arthur's round table, and is frequently employed as synonymous with knight errant.

PALÆOGRAPHY (Gr. *palaios*, old, and *γραφω*, to write), the science of deciphering ancient inscriptions, whether on stone, metals, wood, baked clay, wax, linen, the bark or leaves of plants, or on parchment. The subject is divided into different heads, according to the character of the inscriptions or material on which they are found, and is treated in this work under **CUNEIFORM INSCRIPTIONS, DIPLOMATICS, HIEROGLYPHICS, MINIATURE PAINTING, PALIMPSEST, &c.**

PALÆOLOGUS, the name of a Byzantine family, first mentioned in history in the 11th century, and which occupied the throne of Constantinople from 1261 to 1453, the year in which that city was taken by the Turks. The first emperor of the family was Michael VIII.; the last, Constantine XIV., was killed while fighting in defence of his capital. A member of this family, Theodorus Comnenus, a son of Andronicus II., received the principality of Montferrat in Italy in 1305, in right of his mother Violante, and in the hands of this branch it remained until 1538. Another branch of the house reigned in the Morea from 1380 to 1460. Descendants of the Palæologi were still living in the 17th century.

PALÆONTOLOGY (Gr. *palaios*, ancient, *ων*, being, and *λογος*, a discourse), the science which treats of the fossil remains of plants and animals found within the earth's strata. These are, for the most part, unlike those species now existing upon the surface of the earth or inhabiting its waters. In the progress of this science light has been mutually derived from and thrown upon many correlative sciences; for the discoveries in fossil flora and fossil fauna bear the same relation to our knowledge of recent vegetation and existing animals, that the researches in archaeology bear to our known historic records; the monuments of antiquity are often an index to the true understanding of the succeeding conditions. The determination of these remains of extinct species has led to careful comparisons with known living forms; and since it often happens that these fossil remains are very imperfect, consisting, among vertebrate animals, of a few bones or teeth, or bony plates of fishes, the comparisons have been carried to an extreme minuteness; and thus the structure of living animals has be-

come better known. The same is true of the lower orders of animals and of plants. The requirements created by the study of many of these subjects have induced a reinvestigation of analogous living forms. The study of the embryonic development of some existing species has shown that their progressive phases were fixed and perfect forms in the earlier creations. It is in this perhaps that we may see indicated a certain progression in animal forms, inasmuch as in such instances that which was the finished and complete type is now only the undeveloped embryo of a higher organization. Again a rare form or representation of a group, occurring at an earlier period, becomes more fully developed at a later era or in the present creation; while many existing forms, of which there are few species in the living world, have been found much more fully represented in former creations. It thus becomes clear that the present more complete classifications both of botany and zoology could never have been reached except through the study of the extinct forms. These sciences have thus become better defined, and their arrangement and classification more natural and true, as well as greatly extended. It was formerly considered that mineralogy was the science on which geology most depended; and certainly there is room for mineralogy to aid and sustain geology, since it is not possible for the sediments of distinct geological epochs to give mineral products more similar than the organic contents, so that peculiar mineral characters will be found to mark different geological formations. Moreover, the physical conditions of surface and the nature of the sediments have determined the existence of certain forms of plants and animals during each period. There is thus a mutual alliance between geology, palæontology, and mineralogy. But it is to the science of palæontology that geology is by far the more indebted, since the study of fossil remains has established the order of succession among the stratified deposits of the earth's crust, and the relative position of each formation is better defined by its contained fossils than by any other means whatever.—The physical nature and condition of the older metamorphic strata, in which we have no remains of animals (though these may have existed and become obliterated through physical and chemical changes), prove the conditions of sea and land and distribution of sediments to have been essentially the same as in the present oceans. The extensive limestone formation renders it probable that the ocean of that period was inhabited, although of the inhabitants we know nothing. Palæontology however has shown that from the remote period of the Potsdam sandstone of the American continent, and the Cambrian rocks of Europe, the ocean was peopled by numerous forms of animal and vegetable life. We know that the tide ebbed and flowed, that the waters were agitated by storms, and even that

the sands laid bare by the ebb of tide were rippled by the wind and trailed by the animals of that primeval ocean. From that period at least light and heat, cloud and sunshine, rain and wind have refreshed and fertilized the earth, which teemed with animal and vegetable existences. The testimony of living things is found in their fossil imprints, the earliest evidences of life in the remains of plants or animals imbedded in the sediments of these ancient sea bottoms, or stranded upon their shores. Through unnumbered ages life has presented its varied forms without cessation from its first appearance on the globe; though individuals and species have disappeared, so that each successive epoch, each new physical condition, whether of ocean bed or shore, or of marsh or dry land, presents us with its new and peculiar fauna or flora. In the course of these incalculable periods the aspect and character of the living forms have changed, and there has been, if not a regular progression, yet in the main a wonderful advance over the earlier organisms. It is to palæontology that geology is indebted for its rapid advances, and the certainty with which its determinations are made at different and distant points in the sedimentary fossiliferous strata. The careful study of the rock formations shows that certain groups of strata may be identified by their fossil remains; or in other words, the beds of limestone, sandstone, shale, &c., have each in their turn formed the bed of an ancient ocean, where the now fossil forms then lived, died, and their remains were imbedded, and are still preserved in the solid rock. The refinement to which this study has been carried has enabled us to distinguish by a few fossil forms the relative position of certain beds, and to learn that their position is never reversed.—The table on the following page indicates the relative positions of the geological formations, with their approximate maximum depth or thickness. This exhibits the American strata to the coal measures inclusive, with their organic remains; and the parallelism with European formations can be readily learned. Above the coal measures the series in direct sequence in this country is only found along the eastern slopes of the Rocky mountains. On the eastern shores of the continent we have some limited areas of the new red and jurassic formations, and also cretaceous and tertiary strata in great extent. The floras and faunas of the formations intermediate between the coal measures and the cretaceous, in this country, are at this time so little known, that the fossil characters given are based upon what is known of them in Europe. The fossils given in the subsequent table of strata, in the order in which they characterize the formations, are here arranged in their zoological relations:

PROTOZOA.

CLASS I. AMOEBOZOA. Of fossil sponges, *palæospongia* and *acanthospongia* occur in lower silurian in Europe, in America, in the upper silurian, *astyspongia*, *astraspongia*, and *palæomanon*. *Stromatopora*, which is placed by some naturalists among sponges, occurs abundantly in the Niagara group, and near the base of the lower Helderberg forms a bed of great extent and often 4 feet in thickness, and is widely distributed in the United States. It is found in the Wenlock limestone of England. Other genera occur in devonian, permian, triassic, oolite, and chalk.

CLASS II. FORAMINIFERA. Of this class of animals *Ammonia* is abundant in the carboniferous limestones of Ohio, Illinois, Iowa, Missouri, and Kansas. It forms layers of several inches and even of feet in thickness in the carboniferous limestone of Russia. The foraminifera obtain their greatest force in the eocene period, where the nummulites constitute immense masses. The nummulitic limestones are found in southern Europe, northern Africa, India, the United States, and also in Jamaica; the most common form is seen in the building stone of the great pyramid of Egypt. *Receptaculites*, which is probably a foraminifer, is very abundant in the Galena limestone, one species being a foot in diameter. It occurs also in the Niagara limestone.

CLASS III. INFUSORIA. These microscopic organisms occur in the tertiary of America and Europe, and constitute important masses. This class of animals is exceedingly interesting as forming a connecting link with past creations, many species identical with living ones being found in the chalk, and even as low as the oolite.

INVERTEBRATA.

PROVINCE I. RADIATA. *Polyp.*

CLASS I. HYDROZOA. The *graptolites* are characteristic lower silurian fossils. *Dictyonema* is known from the lower silurian to the Hamilton group or devonian. *Oldhamia*, the oldest known fossil of Europe, is probably a graptolitic genus.

CLASS II. ANTHOZOA (corals and madrepores). The lamelliferous or stony corals attain a great development in the silurian period, and are abundant in the devonian; they are less numerous in the carboniferous period, and again become abundant in the jurassic.

CLASS III. BRYOZOA. The most common palæozoic form is *fenestella*, which becomes remarkably developed in the carboniferous period in the genus *Archimedes*, having elongate, spiral axes. Other forms of bryozoa continue to the tertiary.

CLASS IV. ECHINODERMATA. This class is arranged under 6 orders:

1. *Orinoidea* (crinoids).
2. *Cystoidea* (cystideans).
3. *Blastoidea* (pentremilites).
4. *Asteroidea* (sea stars).
5. *Echinoidea* (sea urchins).
6. *Holothuroidea* (sea cucumbers).

The cystideans have their greatest development in lower silurian strata, where crinoids also occur in large number. In upper silurian rocks there are fewer cystideans, while crinoids are abundant. In the devonian the *blastoids* are common, while crinoids are more abundant, and cystideans few or none. The greatest developments of *crinoidea* and *blastoids* occur in the carboniferous period. The *asteroidea* begin in the lower silurian, and are comparatively rare fossils to the close of the palæozoic era. The *echinoidea* begin in the devonian, are common in the carboniferous period, and are far more abundant in the later geological era.

PROVINCE II. ARTICULATA.

CLASS I. ANNELIDA. The tracks of these animals are found on the surfaces of the Potsdam sandstone of America and the cambrian rocks of Europe; and also in other palæozoic strata.

CLASS II. CIRRIPEDES (barnacles). These fossils are rare in the eocene, and more abundant in later periods.

CLASS III. CRUSTACEA.

Entomostraca. This class occurs in several genera of trilobites at the base of the Potsdam sandstone, followed by other trilobitic genera to the close of the palæozoic period. Near the end of the upper silurian period occur the remarkable fossils, *eurypterus* and *pterygotus*; while *ceratiocaris* appears a little earlier, and is followed in higher beds by the *dithyrocaris*.

Malacostraca. This class of crustaceans is found in oolite and tertiary.

CLASS IV. INSECTA. Fossil remains of insects have been found in the lower coal measures, and more abundantly in the lias limestone of Europe. Fossil spiders are found in the Solenhofen slates, and in the tertiary marls of Aix.

PROVINCE III. MOLLUSCA.

CLASS I. BRACHIOPODA. These in the palæozoic rocks are everywhere abundant, and the best guides. *Lingula* occurs in the earliest palæozoic formation, and continues to the present time. *Orthis* is one of the oldest and most

TABLE OF STRATA WITH THE CHARACTERISTIC ORGANIC REMAINS.

TERTIARY.	SECONDARY.	PALÆOZOIC.	STRATUM	THICKNESS	ORGANIC REMAINS
			Drift and alluvium.		Man with the associated animals and plants.
			Pliocene.	800 to 1,000 feet.	Mammalia and birds; foraminifera and infusoria; lamellibranchiata and gasteropoda abundant; corals and bryozoa; land plants resembling the existing flora.
			Miocene.	1,000 to 2,000 feet.	
			Eocene.		
			Chalk and greensand.		Saurians (<i>mosasaurus</i> , &c.); fishes, teeth of sharks abundant; echinidea; cephalopoda (<i>ammonites</i> , <i>scaphites</i> , <i>vacuities</i> , &c.). Brachiopoda and accephala; bryozoa and sponges abundant.
			Wealden.		Large saurians, fishes, mollusca, &c. Land plants.
			Upper oolite.		
			Middle oolite.		Marsupial mammals; cephalopoda (<i>ammonites</i> , <i>belemnites</i> , &c.); corals; echinidea; crinoidea; brachiopoda; lamellibranchiata; gasteropoda; land plants.
			Lower oolite.		
			Lias.		Large saurians; fishes; cephalopoda (<i>ammonites</i> and <i>nautilus</i>); lamellibranchiata; few brachiopoda; crinoidea and other echinodermata.
			Triassic system, or new red sandstone.		Traces of mammals; wingless birds, &c., chiefly known by foot marks.
			Permian system.		
			1,000 + feet.		REPTILIA. Corals; few brachiopoda, lamellibranchiata, gasteropoda.
			Coal measures and conglomerata.		
			1,000 to 8,000 feet.		LAND PLANTS. Batrachian reptiles, insects, and fishes; crinoidea, bryozoa, brachiopoda, lamellibranchiata; gasteropoda, cephalopoda. The crinoidea, brachiopoda, corals, and bryozoa occur in intercalated masses of limestone.
			Kaokaskia limestone.		
			St. Louis limestone.		CRINOIDEA, Echinoidea, blastoidea, bryozoa, corals, fish teeth, brachiopoda, lamellibranchiata; gasteropoda few, cephalopoda rare; crustacea.
			Warsaw limestone.		
			Keokuk limestone.		
			Burlington limestone.		
			800 to 1,000 feet.		
			Red shales.		
			8,000 feet.		Plants. Tracks of reptiles.
			Catskill mountain group.		
			8,000 to 6,000 feet.		Remains of fishes; a few lamellibranchiata.
			Chemung group.		
			Shales and shaly sandstones.		Brachiopoda and lamellibranchiata abundant; crinoidea; bryozoa. Gasteropoda common; cephalopoda rare; crustacea rare.
			1,000 to 1,500 feet.		
			Portage group.		
			Shales and sandstones.		Fucoides and land plants; brachiopoda and lamellibranchiata few; cephalopoda common in the genus <i>goniatites</i> .
			1,000 feet.		
			Hamilton group.		
			Shales, limestones, and shaly sandstones.		Fucoides and land plants, but not abundant; brachiopoda and lamellibranchiata abundant; corals, crinoidea, and bryozoa. Gasteropoda common; cephalopoda (<i>nautilus</i> , <i>goniatites</i> , and <i>orthoceratites</i>); crustacea and fishes.
			1,000 to 1,500 feet.		
			Upper Helderberg group.		
			Limestones.		Corals; crinoidea; bryozoa, brachiopoda; lamellibranchiata few; gasteropoda; cephalopoda (<i>cyrtoceras</i> , <i>goniatites</i> , and <i>orthoceras</i>); crustacea; remains of bony plates and spines of fishes.
			300 to 500 feet.		
			Oriskany sandstone.		Brachiopoda and gasteropoda abundant; lamellibranchiata few; crinoidea.
			100 to 500 feet.		
			Lower Helderberg group.		
			Limestones and shales.		Brachiopoda and gasteropoda abundant; corals; bryozoa; crinoidea; lamellibranchiata and cephalopoda few; crustacea.
			800 to 1,000 feet.		
			Waterlime group.		
			100 feet.		Crustacea of the genera <i>ourypterus</i> , <i>pterygotus</i> , and <i>ceratiocaris</i> ; few other fossils.
			Onondaga salt group.		
			1,000 feet.		Few fossils.
			Niagara group.		
			Shales and limestones.		Sponges; corals; crinoidea; cystidea; bryozoa; brachiopoda. Lamellibranchiata and gasteropoda few; cephalopoda abundant; crustacea abundant.
			500 feet.		
			Clinton group and Medina sandstone.		
			8,000 feet.		Fucoides; graptolites; brachiopoda; a few crustaceans and crinoids.
			Hudson river group.		
			6,000 feet.		Fucoides; graptolites; corals; crinoidea; bryozoa; brachiopoda; lamellibranchiata; gasteropoda; cephalopoda; crustacea.
			Trenton limestone group, including Trenton, Black river, Birdseye, and Chazy limestones.		
			1,000 to 8,000 feet.		Marine plants; graptolites; corals; bryozoa; brachiopoda; lamellibranchiata; gasteropoda; cephalopoda in several genera, especially <i>orthoceras</i> , which is in great abundance.
			Lower magnesian limestone or calciferous sandstone, and Potsdam sandstone, equivalent to the cambrian.		
			1,000 to 6,000 (?) feet.		Crustacea and mollusca (chiefly <i>lingula</i> and <i>theca</i>); graptolites; annelida (tracks and trails); marine plants.

characteristic genera, and widely distributed in the older calcareous rocks, usually associated with *strophomena*. The order of time in which the principal paleozoic genera appear is about as follows: 1. *Lingula*, *obolus*, *orthia*, *strophomena*, *leptaena*, *rhynchonella*, *pentamerus*, *dictyna*, *trematia*. These, except *Lingula*, appear nearly at the same time. 2. Added to these are *chonetes* and *streptorhynchus*, with *pentamerus* more abundant, *merista* and its associates, *spirifer*, and *atrypa*. 3. In lower Helderberg limestones *Rensselaeria*; and of the rhynchonellid type the genus *Eatonia*. This latter becomes conspicuous in the Oriskany sandstone, where *orthia* assumes extravagant proportions; and the *strophomena* type of earlier rocks takes other characters, becoming the *strophodonta*, so characteristic of the higher groups. 4. Above the Oriskany sandstone, and characteristic of the upper Helderberg and Hamilton groups, are found *productus*, *leiorhynchus*, *athysia*, *tropidoleptus*, &c., and at the same time certain forms of *orthia* are abundant; *streptorhynchus* is more common than in the middle period, *chonetes* abundant; *strophomena* proper has disappeared, and *Rensselaeria*, which marks the base of the formation, soon dies out. In the Onondaga group, *productoid* forms are far more largely developed, with a diminution of all the others.

CLASS II. LAMELLIBRANCHIATA. The fossils of this class are most abundant in the devonian period, though occurring in lower silurian and some parts of upper silurian strata; they are abundant in the shales of the devonian period and in all the succeeding strata, gradually acquiring a preponderance over the brachiopoda in later times.

CLASS III. GASTEROPODA. These fossils occur in the earliest geological periods. *Maclurea* is found as low as the calciferous sandstone.

CLASS IV. CEPHALOPODA. These have existed in all geological ages, and present various and conspicuous forms. The *orthoceratites* are most abundant and remarkable in the lower silurian strata, associated with *litules*, *cyrtoceras*, &c., and continuing to the coal measures inclusive. In the devonian and carboniferous periods *goniatites* and *nautilus* predominate, while in the jurassic period *ammonites* are in great profusion, with other genera; and in the cretaceous period *ammonites*, *scaphites*, *turritites*, and *baucites*.

VERTEBRATA.

CLASS I. PISCES.

Order I. **PLAGIOSTOMA** (sharks, rays). Upper Helderberg and Hamilton groups in America; Ludlow rocks in Europe; more abundant in tertiary.

Order II. **HOLOCEPHALI** (chamaroid fishes). Oolite.

Order III. **GANOIDEI**. Old red sandstone or Catskill mountain group; carboniferous formation.

Order IV. **ACANTHOPTERI**. Found only in modern geological periods.

Order V. **ANOCANTHINI**. Belonging to modern geological periods.

CLASS II. REPTILIA.

AMPHIBIA.

Order I. **GANOCEPHALA** (*apateon* or *archegoniasaurus*). Found in the coal measures in Europe.

Order II. **LABRINTHODONTA**. New red sandstone.

SARIA.

Order I. **THECODONTIA**. Permian and triassic of Europe; one genus is found in the new red of Prince Edward's island, North America.

Order II. **CRYPTODONTIA**. One genus in the new red sandstone of New England, and one has been found in South Africa.

Order III. **DIOTYODONTIA**. Remains of this family have been found in South Africa.

Order IV. **ENALIOSAURIA** (sea lizards). *Plesiosaurus*, *Ichthyosaurus*, &c. This order of animals is remarkably developed in the jurassic period.

Order V. **DINOSAURIA**. *Iguanodon*, &c. This order begins in the triassic, and acquires its full development in the oolitic period.

Order VI. **PTEROSAURIA**. Fossil pterodactyls are peculiar to the secondary period.

Order VII. **CROCODYLIA** (crocodiles).

1. *Amphicollia*. Lias to chalk inclusive.

2. *Optidocollia*. Lias, oolite, and Wealden.

3. *Phocollia*. Cretaceous in North America and tertiary in Europe.

Order VIII. **LACERTILIA**. *Moscosaurus*. Cretaceous in North America and Europe; also in tertiary.

Order IX. **OPHEIDIA** (serpents). Tertiary and slates of Oningen.

Order X. **CHELONIA** (turtles). Tracks of these animals are found in triassic sandstone; their bones occur in oolite, cretaceous, and tertiary.

Order XI. **BATRACHIA**. The remains of batrachian reptiles are found in carboniferous and triassic to tertiary.

CLASS III. AVES.

The first indications of birds are their footprints in new red sandstone. The bones of birds occur in tertiary, and obscurely in cretaceous.

CLASS IV. MAMMALIA.

Order **HERBIVORA**. The greatest development of the herbivora is in the older tertiary, *palaeotherium*, *anaplotherium*, &c., of Europe; *palaeotherium*, *oreodon*, *archaotherium*, *anchitherium*, *rhinoceros*, &c., of America. In the later or post tertiary are found the larger forms, *mastodon*, *elephas*, &c., of Europe and America; and the *megatherium* and *mylodon*, which are American types.

Order **MARSUPIALIA**. These range from the herbivora to the carnivora. The earliest known mammals belong to this order. *Microlestes*, *amphilestes*, *phascoclerium*, and others, are known in the oolitic period of Europe; and *dromatherium* in beds of about the same age in America.

Order **CARNIVORA**. Fossil remains of carnivores are found not earlier than the tertiary period. *Machairodus* occurs in America associated with the *oreodon*, &c. The remains of this order in Europe all belong to newer tertiary.

Order **CETACEA**. Several genera appear in the tertiary period of Europe and America.

—The representatives of the vegetable kingdom are far less conspicuous in the older strata than those of the animal kingdom; and it is only in later paleozoic rocks and the subsequent epochs that these remains furnish the palæontologist with important materials for comparison. In closing this succinct sketch of the extensive science of palæontology, we may present the names of the classes recognized in the vegetable kingdom, to show the order of their appearance in the geological history. These classes are in the order of their organization.

CRYPTOGAMOUS OR FLOWERLESS PLANTS.

CLASS I. ANOPHYTES.

1. *Musci* (mosses).

2. *Hepaticae* (liverworts).

To which may be added the *Juncus*, *algae*, and *liebens*.

CLASS II. ACROGENS.

1. *Equisetacea* (horsetails).

2. *Filices* (ferns).

3. *Lycopodiaceae* (ground pines).

4. *Hydropteridae*.

PHENOGAMOUS OR FLOWERING PLANTS.

CLASS III. MONOCOTYLEDONOUS OR ENDOGENOUS PLANTS.

More than 20 orders are included under this class, among which are the grasses, sedges, reeds, liliaceous, and many other plants.

CLASS IV. DICOTYLEDONOUS OR EXOGENOUS PLANTS.

Under the sub-class of angiospermous plants are included more than 100 orders, in which are embraced all the ordinary forest trees (except the *coniferae*), beside the far greater proportion of the ordinary flowering plants.

Under the sub-class of gymnospermous plants are included all the *coniferae*.

Notwithstanding, as before remarked, there is in the lapse of time a great advance over the earlier organisms, it is not possible with our present knowledge to trace a gradual or constant progression throughout all the successive geological periods. The organisms, whether animal or vegetable, have been adapted to or consequent upon the existing condition of the earth's surface during each period. The materials or strata containing organic remains, now presented to our examination in continental areas, were for an almost incalculable period the sediments of an ocean bed, without indications of dry land, or with only such indications as are furnished by the remains of animals which resemble those of present littoral origin. During all the time to the end

of the silurian period, the only remains of plants are of marine origin, such as *algæ* or *fruticæ*; while some of the forms thus referred may be plant-like sponges. The earliest evidence of dry land vegetation began with those conditions which ushered in the coal period, or what is termed the devonian; for the general character of the flora, so far as known, in the devonian period in America, remains essentially the same throughout the carboniferous period. In this epoch we have land plants of the acrogenous forms, such as ferns, in abundance; the *equisetacea* in the *calamites*; the *lycopodiacea* in the *lycopodites*, *lepidodendron*, &c.; while *stigmaria*, *sigillaria*, and other forms, constitute orders allied to those mentioned. During this period, the phenogamous plants are comparatively rare. The conditions of the surface favored only the development of the lower orders of vegetation; and we know that the low land of this period was subject to influx of the ocean, which has given alternating strata of land or shore deposits with land plants, and marine calcareous strata with shells and other marine animals only. Nor is it to be understood that, because of the great amount of land vegetation at this period, the entire surface of the present continent was dry land; and that plants everywhere abound at the same time and are imbedded in the same strata. So far from this being true, in the west and south-west land plants are extremely rare or altogether wanting in rocks of this age; while strata of marine origin, with marine animal remains, take their place. At each successive geological period the flora appears to have approached more nearly that of the present period, not however the flora in the same latitude, for the older floras of the temperate zones have assumed in many respects a tropical aspect. It is however in the cretaceous and tertiary periods that the flora approaches more nearly that of the present, embracing indeed many genera of the existing flora of the temperate latitudes. In the successive faunas, too, even of the ocean bed, we are to take into consideration the physical conditions existing. In the very early periods coarse and fine sediments are found, indicating, if not shore lines, at least shallow and disturbed water on the one hand, and deeper seas with quiet water and finer sediments on the other. The fossil shells of the coarser deposits are to a great degree wanting in the finer sediments, and *vice versa*. The recurrence of similar sediments at different periods, caused doubtless by a recurrence of similar physical conditions, is always accompanied by a similar fauna, sometimes indeed so similar as not to be readily distinguished from each other. In the study of species of the successive faunas, we find that in every period, as in the present, their geographical distribution has been influenced as in the present seas. By far the greater number of species are limited in their horizontal extension; while some are everywhere found so far as any evi-

dence of the existence of the formation remains. This geographical extension of the species does not always correspond with the nature of the sediments; for while in the Trenton limestone period we have a large number of the brachiopoda extending over wide areas, even as far westward as the formation is known, the same is not true of the brachiopoda of the Hamilton group, where the physical conditions are equally uniform; for in this nearly all the known eastern species are replaced by other forms on the west of the Mississippi river. This fact however must not be used as an argument in favor of gradual climatic or other permanent changes; for again, during the carboniferous period, we find certain forms of brachiopoda having even a wider geographical range than in any of the preceding periods. —Our space does not permit a discussion of the causes that have operated in the distribution of the successive faunas and floras of the several geological periods; but that these have successively appeared and disappeared is well ascertained in every part of the habitable globe. Although we may show the existence of causes sufficient to destroy the faunas in many epochs of the earth's history, the repeopling of the same areas by other races, after a moderate lapse of time, is a problem we are not prepared to solve. Of the succession or coming in of new species we have everywhere the most palpable evidence; a kind of evidence, moreover, that in a large proportion of the examples precludes the possibility of their having been derived from sources far distant from the spot where we first behold their imbedded exuvia.

PALÆOTHERIUM (Cuv.; Gr. *παλαιος*, ancient, and *θηριον*, animal), the type of a tribe of fossil pachyderms, belonging to the family of *perissodactyla* (Owen), or those having an uneven number of toes, intermediate between the tapir and rhinoceros. The form was like that of the tapir; the raised nasals show that it had a small flexible proboscis; the feet were 3-toed; it had projecting canines, and molars $\frac{1}{2}$, the upper like those of the rhinoceros, the first smallest and single lobed, and the lower formed by 2 successive crescents with their convexity external, the first single and the last one trilobed. Several species are described by Cuvier and others, of which the largest and best known is the *P. magnum* (Cuv.), of the size of a horse, but of a stouter form; there are others varying in size from that of a hog and sheep to that of a hare. They belong especially to the gypsum of Europe (eocene), are abundant in the plaster quarries of Montmartre, near Paris, and extend even into the lower miocene; the species differ little, except in size.

PALÆPHATUS, the name of four Greek writers mentioned by Suidas. The first was an epic poet of Athens, whose origin was considered mythical, and whose age is unknown. Suidas says that he wrote the *Cœmopœa*, "The Birth of Apollo and Diana," "The Contest of Minerva and Neptune," &c. The second, who

lived in the time of Artaxerxes Mnemon, was from Paros or Pirene, and is said by Suidas to have written a work on "Things Incredible." The third was a historian, a native of Abydos, who lived in the time of Alexander the Great, and is stated to have been on intimate terms with Aristotle. The fourth was a grammarian of Egypt, or of Athens, to whom several works are attributed by Suidas. There is extant a small treatise, entitled "Palæphatus on Things Incredible," which is evidently an abridgment of a larger work. It is uncertain who its author was, and if one of those above mentioned, it could only have been the fourth, as the treatment of the subject bears evidence of a later age than that of Palæphatus of Paros. He treats the Grecian myths according to the semi-historical theory, claiming that they had a foundation in fact, but were disguised and changed by the license of the poets and of popular tradition. (See Grote, "History of Greece," vol. i. cap. 16.) The first edition of Palæphatus was printed in 1505 at Venice in folio, along with other writers, by Aldus Manutius. The best edition of the text is that of Westermann in his *Scriptores Poetico Historici Græci* (Brunswick, 1848). In 1671 a Latin translation of the work was published at Cambridge, and in 1771 a French translation at Lausanne.

PALAFOX Y MELZI, José, a Spanish patriot, born in Torre del Alfranca, Aragon, in 1780, died in Paris in 1847. His family was one of the oldest in Aragon. At an early age he entered the royal body guard, and became part of the military household of the king of Spain. As an officer in the body guard, he accompanied the royal family to Bayonne in 1808. The king was retained a prisoner, but Palafox escaped in a peasant's dress and repaired to his estate near Saragossa. In the same year that revolted city was menaced by the French army under Lefebvre-Desnouettes, and the populace proclaimed him captain-general of Aragon (May 28). He is represented by Sir W. F. P. Napier and some Spanish historians as totally unfitted for the position, and indebted to others for the temporary success of his defence. Soldiers from the adjacent country were called into the city, barricades were erected in every street, and nearly every house was made a point of defence. After a siege of 61 days the French retired; but they returned in greater force successively under Moncey, Mortier, Junot, and Lannes, and the city capitulated in Feb. 1809. Palafox was not in active command at the time, being ill of a prevalent epidemic. The capitulation provided that Palafox should depart free, and that no one should be molested; but the city was pillaged, blood profusely shed, and Palafox, still prostrate with the malady, was sent a prisoner to Vincennes. He was only released upon the restoration of Ferdinand VII. in 1813, when he returned to Madrid with the king, and was confirmed in his position of captain-general of Aragon. Nevertheless he pronounced in 1820 for the constitution, and in

1828 signed a protest against the royal power. In 1838 he joined the party of Queen Isabella, and was soon after imprisoned upon suspicion of some correspondence with the queen's enemies, but was liberated upon proof of his innocence. In 1836 he was made duke of Saragossa.

PALAMEDES, a Grecian hero, son of Nauplius and Clymene. He served in the expedition against Troy, and for a time was commander-in-chief in place of Agamemnon, whose measures he opposed. According to the old Cyprian epic, he was drowned while fishing by Diomedes and Ulysses; but a later tradition is that he was accused of treason by Ulysses, who concealed gold or a forged letter from Priam in his tent, and then charged him with having been bribed by Priam. When Palamedes was led out to die, he exclaimed: "Truth, I lament thee, for thou hast died even before me." Still another tradition represents him to have been let down into a deep well, which Ulysses and Diomedes had falsely asserted to contain treasure, and then stoned. He is not mentioned by Homer, but was made the subject of tragedies by Æschylus, Sophocles, and Euripides. The unjust death of Palamedes was alluded to by Socrates in his last speech to his judges.

PALATE, the bony and muscular partition which separates the mouth in vertebrate animals from the anterior and posterior nasal cavities. The bony or hard palate forms the roof of the mouth, and consists of the horizontal portion of the superior maxillary bones in front and of the palate bones behind; these form a parabolic arch, bounded in front and on the sides by the upper teeth and their sockets, covered by mucous membrane, and giving attachment posteriorly to the *velum palati* or soft palate. The width, contractions, elevations, extent, and perforation by larger or smaller incisive or other openings, are valuable characters in estimating the rank of the various subdivisions of vertebrates, those being the highest in which this part is broadest, uniform, and least pierced by foramina, making a complete partition as in man; the changes in the palate bones are connected with corresponding modifications in the sphenoid, and consequently with the whole anatomy of the skull. The soft palate is a movable, soft, and muscular partition, lined by mucous membrane; its free edge floats above the base of the tongue, having in its centre a conical appendage, the *uvula*, and on its sides the so called "pillars," the anterior directed obliquely forward and the posterior vertically, the triangular interval between them being occupied by the tonsils; the mucous membrane is studded with mucous follicles; the arteries are derived from the external carotid, and the nerves from the facial, trifacial, glosso-pharyngeal, and from Meckel's ganglion. The muscles of the palatal regions are the *circumflexus palati*, from the internal surface of the pterygoid process to the velum, stretching horizontally the soft palate, and dilating the Eustachian orifice; the *levator*

palati, from the petrous portion of the temporal bone, raising the palate and carrying it backward; the *aspygos uvula*, vertical, forms the chief part of this organ, raising it with the palate; the *palato-pharyngeus* forms the posterior pillar of the palate, depressing the velum and elevating the pharynx; the *constrictor isthmi faucium*, in the anterior pillars, extending from the base of the tongue to the velum, depresses the latter and elevates the former. The soft palate is endowed with acute sensibility, and in the neighborhood of the uvula and its arches, and to a less degree on its anterior portion, ministers to the specific sense of taste. The mucous membrane of the palate is subject to inflammations, and the bones are attacked in syphilis and other cachectic diseases; these parts are also liable to arrests of development, in which the mouth and nasal cavities communicate through a fissure, with or without hare lip. In this deformity deglutition is difficult, sucking impossible, and the voice indistinct and nasal; the interference of surgery is necessary for its relief, and by the operation of staphyloplasty, which consists in placing and keeping in apposition the incised edges of the fissure, a partial or complete closure may be effected; where this is impracticable, relief may be obtained from gutta percha or metallic plates.

PALATINATE, THE UPPER AND LOWER, two separate states of ancient Germany, not contiguous, though under one ruler. Their territory is now comprised in that of France, Bavaria, Hesse-Darmstadt, and Prussia. The word palatine is related to palace, and as a title dates from the time of the Merovingian kings of France, connected with whose court was a high judicial officer called the *comes palatii*, a master of the royal household who had supreme authority in all causes that came by fiction to the king. When the sovereign chose to confer a peculiar mark of distinction upon the holder of any particular fief under him, he granted the right to exercise the same power within his province as the *comes palatii* exercised in the royal palace. With the function went the title of *comes palatinus*, or count palatine; and from the ruler the district under him became finally known as a palatinate.—The Upper Palatinate was bounded by Baireuth, Bohemia, Neuberg, Bavaria, and the territory of Nuremberg, and now forms in the kingdom of Bavaria the circles of Upper Palatinate and Upper Franconia. Its area was about 2,780 sq. m. The Lower Palatinate was situated on both sides of the Rhine, and was bounded by Katzenellenbogen, Wurttemberg, Baden, Alsace, Lorraine, and Treves. The chief cities were Mannheim and Heidelberg. Its area was about 1,600 sq. m., and it comprehended the principalities of Simmern, Zweibrücken, Veldenz, Lautern, and the county Palatine properly so called. The hereditary sovereignty of the counts palatine over these districts dated from the 11th century. In 1777 the elector Charles Theodore succeeded to the sovereignty, and on his inheriting Bavaria

(1778) the two states were united. During the wars of the French revolution, France took possession of that part of the Palatinate that lay on the left bank of the Rhine, but after the fall of Napoleon it was returned to Bavaria.

PALATINE (Hung. *nádor*), under the Hungarian constitution, the title of the royal lieutenant, in later periods officiating as mediator between the nation and king, and as president of the upper house of the diet. The archduke Joseph, brother of the emperor Francis, and his son Stephen, were the last palatines, the latter officiating at the beginning of the Hungarian revolution of 1848.—The term is also used as a title (Pol. *wojewoda*) of the governors of the larger divisions or provinces (*województwa*, palatinates) of independent Poland.

PALEMBANG, a Dutch province on the E. coast of the island of Sumatra, bounded by the strait of Banca, the provinces of Lampong and Bencoolen, and the Battah country; area, 18,000 sq. m.; pop. about 250,000. It is for the most part a marshy plain, watered by several large rivers, and covered by extensive forests. The W. part is mountainous. The soil is fertile, and the climate hot and moist, but not unhealthy. The cultivated crops are rice, sugar cane, tobacco, gambier, indigo, coffee, and pepper. All the animals of the forests and other parts of Sumatra are found in Palembang; and the chief domesticated ones are buffaloes, goats, sheep, hogs, and poultry. The inhabitants consist of the descendants of Javanese, of Malaya, of an aboriginal people called Kumring, and of a wild race known under the name of Kubu, with a few Arabs and Chinese. Up to a recent date Palembang was an independent kingdom, ruled by a sultan, with whom the Dutch had a treaty. In 1811, when Java and its dependencies were occupied by the British, the Dutch officials at Banca fell into the hands of this chieftain, who put the whole of them to death, thinking thus to ingratiate himself with the new rulers. The English sent an expedition which dethroned him, annexed part of his dominions, and placed his younger brother in authority. When Java was restored to the Dutch, he resumed his rule, and kept them at defiance till 1821, when Palembang was finally subdued.—The capital, **PALEMBANG**, is situated on the Musi or Sungsang, the most important river of Sumatra, about 50 m. above its mouth, in lat. 2° 58' S., long. 105° E.; pop. 25,000. It lies on both banks of the river, which is here 400 yards broad with a depth of from 8 to 9 fathoms, and sufficient water all the way from the sea for large vessels. The only buildings of stone are the mosque and the tombs of the kings. There are several Arab and Chinese merchants at Palembang, and a trade is carried on with Java, Banca, Siam, China, and the English settlements in the straits of Malacca.

PALENCIA, a province of Spain, in Old Castile, bounded N. by Santander, E. by Burgos, S. by Valladolid, and W. by Leon; area, 4,580 sq. m.; pop. in 1857, 185,970. It is

watered by the Carrion, Cieza, Pisnerga, and several other rivers, and the canal of Castile passes through it. With the exception of a portion of the N. part which is mountainous, the surface is level, and almost totally devoid of trees. Coal, chalk, gypsum, saltpetre, and copper ore are found. The climate is cold but healthy, and the soil is fertile; wine, grain, vegetables, and fruits are produced. Blankets and other woollen goods are manufactured. The province contains about 600 elementary schools.—The capital **PALENCIA** (anc. *Pallantia*), is situated on the left bank of the river Carrion, 117 m. N. N. W. from Madrid; pop. 11,470. The river is crossed by several fine bridges, and the town is surrounded by a strong wall. It contains a cathedral, begun in the 14th century and finished in the 17th, several churches and convents, an episcopal palace, the palace of the king of Navarre, several charitable institutions, among which may be mentioned a founding hospital, an academy and numerous schools, a picture gallery, and a library. About $\frac{1}{3}$ of the population are employed in woollen manufactures. The town was a place of considerable importance in the time of the Romans. In honor of the bravery displayed by the women of Palencia, in their successful defence of the city when besieged by the Black Prince, they were permitted by Juan I. to wear a golden band upon their heads. It was occupied by the French general Foy in 1812.

PALENQUE, Ruins of, the most remarkable aboriginal remains of the continent of America yet discovered, situated on the Rio Chacamas, a branch of the great river Usumasinta, nearly in the centre of the Mexican state of Chiapas, 8 m. S. E. from the small town of Santo Domingo de Palenque, from which they take their name, in lat. $17^{\circ} 30' N.$, long. $92^{\circ} 25' W.$ The remains extend over a large area, as yet but imperfectly explored, and consist of vast artificial terraces, or terraced, truncated pyramids, of cut stone, surmounted by edifices of peculiar and solid architecture, and often of elaborate plan, also of cut stone, covered with figures in relief, or with figures and hieroglyphics wrought in stucco, and showing evidences of having once been painted in brilliant colors. Most of the buildings appear to have been of but one story, but there are several of 2, and also a square tower of 8, perhaps originally of 4 stories. The principal structure, known as the palace, stands on a truncated, terraced pyramid, faced with cut stone, 310 ft. long, 260 ft. broad at the base, and 40 ft. high. It is 228 ft. long, 180 ft. deep, and 25 ft. high, with a broad projecting cornice of stone. It faces the east, and has 14 doorways on each side and 11 at the ends, each 9 ft. wide, with intervening piers between 6 and 7 ft. wide. The whole is constructed of cut stones cemented with a mortar of lime and sand, and the entire face was covered with stucco and painted; but the greater part of this has fallen of or disappeared under the influences of time and the elements. The

piers are ornamented with spirited bass-reliefs in stucco, with borders of hieroglyphics, which, although considerably defaced, show a better knowledge of the proportions and anatomy of the human figure than has been found among the other works of the aboriginal nations of America. The principal doorway is only distinguished from the others by a flight of broad stone steps leading up the face of the pyramid. A corridor 9 ft. wide, covered by a semi-pointed arch, runs all around the building, separated from a similar inner one, of corresponding width, by a solid wall, with a doorway opening from the principal entrance, and pierced with openings in the form of the Greek cross and the Egyptian Tau, probably for purposes of ventilation. The building has 4 interior courts, from all of which open many rooms or chambers, floored with a smooth and solid cement equal to the best found in the ancient Roman baths. The principal courtyard is 70 by 80 ft., and reached by a descending flight of 5 steps 30 ft. broad. On each side are slabs of stone, carved with gigantic figures in bass-relief, 9 or 10 ft. high, adorned with rich head dresses and necklaces, but in attitudes strikingly expressive of pain. The second courtyard, corresponding in length with that just described, but narrower, is also surrounded by a corridor, the piers of which are covered with figures in stucco, or with plaster, which where broken reveals 6 or more coats or layers, each retaining traces of painting, and indicating that the edifice had been so long in use that the plastering required to be several times renewed. From the N. side of the 8d court rises a tower 80 ft. square at its base and 8 stories high, containing within itself another distinct tower, ascended by a narrow stairway, terminating against a dead stone ceiling—thus rendering the purposes of the structure, supposing it to be in its original condition, entirely inexplicable. In the E. corridor of this court are a number of stucco tablets, and one of stone which represents a figure seated cross-legged, after the manner of Buddha in some of the Hindoo sculptures and paintings, on a seat carved with the figures of jaguars, before which kneels another figure, richly dressed, in the act of presenting some object highly ornamented. A number of hieroglyphical figures occur on the tablet, below which are traces of a table of stone, perhaps an altar, which stood against the wall. Connected with the structure are a number of semi-subterranean vaults, and, it is said, others completely sunk in the mass of the pyramid, in which have been found vases containing human remains and many ornaments and minor relics of art. Several of the rooms have traces of altars in them, which stood before broad spaces on the walls, evidently once occupied by tablets, such as are found elsewhere in the ruins, elaborately sculptured with human figures and hieroglyphics.—Beside the building called the palace, there are a number of others of smaller size, but not inferior interest. One of these is des-

ignated by Mr. Stephens in his plan of Palenque as Casa No. 1. It crowns a pyramidal structure of stone, so steep as to be ascended with difficulty, and 110 ft. high measured on its slope, and is 75 ft. long and 25 ft. deep, with solid walls on all sides except the N., which has 5 doorways and 6 piers. The whole front is richly ornamented in stucco, and the 2 corner piers are covered with hieroglyphics, 96 squares to each pier. The 4 piers dividing the doorways are ornamented with female figures, well executed, surrounded with borders of hieroglyphics. The visitor first enters a corridor 7 ft. wide, paved with broad stones, and roofed with a pointed arch formed by overlapping stones. Behind the corridor are 8 inner rooms, with a corresponding number of doorways, between which are massive stone tablets set in the wall, 18 ft. long and 8 ft. high, covered with hieroglyphics, 240 squares or combined figures in each. The 8 inner apartments are dark and gloomy. In the central one, set in the back wall of the building, and fronting the principal entrance, is another tablet of hieroglyphics, 4 ft. 6 in. wide, and 8 ft. 6 in. high. Still another, and in some respects more remarkable structure, is designated by Mr. Stephens as Casa No. 2. The base of the whole is a stone terrace 60 ft. on the slope, with a level esplanade at its top 110 ft. in width, from which rises a pyramidal structure 184 ft. high on its slope, supporting a building 50 ft. long and 81 ft. deep, with 8 doorways opening to the south, the piers between being covered with stucco ornaments, while the outer or corner piers, as in the case of Casa No. 1, contain hieroglyphics. The interior has a corridor paved and roofed as already described, behind which are 8 apartments, the central one the largest, and containing within itself a smaller chamber 18 ft. long and 7 wide, with a tablet of stone 10 ft. 8 in. long and 6 ft. 4 in. high, set in the wall at its back, fronting the principal entrance. This tablet contains a central group of human figures, apparently in the act of making a solemn sacrifice, on each side of which are 6 columns of hieroglyphics, 17 in each. The building is surmounted by what may be called two stories of interlaced stucco work, resembling a high, fanciful lattice, and made up originally in part of human figures, which, according to Mr. Stephens, who judged from the fragments, "in justness of proportion and symmetry must have approached the Greek models."—There are among the ruins other similar structures with tablets covered with human figures in relief and hieroglyphics, all of which seem to have been dedicated to religious purposes. But one edifice, that called the palace, already described, seems to have been designed as a habitation, and its original purpose is doubtless correctly indicated by the name that has been given to it. There are also the remains of an aqueduct 4 ft. in height, and roofed with a pointed arch of overlapping stones. A number of monolithic statues are scattered

among the remains, one of which is 10 ft. 6 in. high, representing an erect figure, with a head dress in the form of a cross.—It may be repeated of these ruins, that no others yet found on the continent exhibit so numerous and marked evidences of skill in architecture and sculpture; and we are irresistibly led to the conclusion that Palenque (anciently there is reason to believe called Na-chan, which in the Tzendal dialect signifies seven serpents) was at one time the centre of the highest form of aboriginal civilization. From the dim light afforded by the ancient paintings and existing and recorded traditions, it seems that it was once the capital of a theocratic state, in which the ruler was "prophet, priest, and king," and which finally gave way to a military republic, resulting in a general disruption and separation of the people; one portion of them, under the lead of "holy men," clothed in white, penetrated into Yucatan and founded the ancient kingdom or theocracy of Mayapan, and built those numerous cities which the Spaniards found occupied, and which now, in their ruins, so closely resemble those of Palenque. In the wanderings of the traditional Cuculcan, called in Mexico Quetzalcoatl, we may perhaps trace the history of these sacerdotal leaders; and in the influence of his teachings on a relatively barbarous people, the origin of a large part of what is known to us as the civilization of Mexico.—Palenque seems to have been in ruins, and its site forgotten, at the period of the conquest. Cortes must have passed close to it in his famous march from Mexico to Honduras, and yet neither he nor the curious and communicative Bernal Diaz, who accompanied him, makes any mention of its existence. Indeed, no knowledge of it had reached the world, so far as can be ascertained, until the year 1750, during the administration of Don Antonio Calderon in Chiapas. The news of their discovery created a considerable interest in Spain, as is proved by the two explorations made by order of the government of that kingdom, in 1784 and 1787, by Bernasconi and Del Rio. It was not however until 18 years afterward that Charles IV. of Spain caused a careful examination of them to be made by Capt. Dupaix, the results of which long remained unknown. Forgotten in the archives of Mexico during the period of the revolution, the three memorials of Dupaix, and the drawings of his companion Castañeda, became finally, by exchange, the property of M. Baradère, who published them in 1834, in a work called *Recueil des antiquités Mexicaines*. In 1834 M. Frederic Waldeck visited the ruins and made many elaborate drawings and plans, which yet remain unpublished; and in 1843 they were explored by Messrs J. L. Stephens and F. Catherwood, and their account, largely illustrated with drawings and plans, was soon after published. (See Stephens's "Incidents of Travel in Central America, Chiapas, and Yucatan," and Catherwood's "Views of the Ancient Monuments of Central America, Chiapas, and

Yucatan.") They were visited still later, in 1846, by M. Arthur Morelet, whose account, destitute however of illustrations, was published in 1857 in Paris (*Voyage dans l'Amérique Centrale*), and translated and published in the United States in 1861, under the title of "Itza, or the Unexplored Regions of Central America."

PALERMO, a province of Sicily, bounded N. by the Mediterranean, E. by the provinces of Messina and Catania, S. by Girgenti and Cattanissetta, and W. by Trapani; area, 2,012 sq. m.; pop. in 1856, 541,826. It is the largest and most populous of the Sicilian provinces. The coast is irregular and the surface is hilly, but there are many very fertile valleys. The country has a general slope N. toward the Mediterranean. Its streams are numerous but small. It produces grain, oil, fruits, almonds, manna, sumach, licorice, and silk.—PALERMO (anc. *Panormus*), capital of the above described province and of the island of Sicily, in lat. 38° 6' N., long. 13° 20' E.; pop. 184,541. It is situated on the N. side of the island, on a deep bay between Capes Gallo and Zaffarana, and in a rich plain which is surrounded on the land side by two distinct mountain ridges. This enclosure between the hills and the sea has been called from its form and beauty the *Conca d'Oro*, or golden shell. The situation is extremely picturesque; the city itself, seen from the sea, with its many spires, domes, and towers, has an imposing and noble appearance. The harbor, formed by a mole 800 feet in length, is spacious and excellent. The city proper is nearly rectangular, and forms an oblong parallelogram, about 4 m. in circumference. The shortest side is that toward the sea. It is surrounded by decayed walls, entered by 12 gates, and defended by bastions. The harbor is moreover protected by a strong citadel and Forts Galita and St. Erasmus, and the lighthouse battery. Palermo is divided into 4 nearly equal parts by two wide streets that intersect each other at right angles in the centre of the city. The longer of these is called *Il Cassaro*, an Italian corruption of the Arabic *Al-Kasr*, "the palace." It runs from the sea to the palace of the viceroy, which is at the inland extremity of the city. The second is the *strada Macqueda*. At their intersection is a large public place, the *Quattro Cantoneri*, which is octagonal in form, having upon 4 sides the vista of these streets, and upon each of the others a handsome building in the Grecian style. The centre of this place is occupied by a fountain, and many statues stand in the various parts of it. There is a larger square before the palace, in which is a bronze statue of Philip IV. of Spain. Numerous smaller streets without any regular plan run into these two, but are all narrower and dirty. The whole city, however, is well paved with large blocks of lava. Frequent obstructions in the form of booths and workshops block up the thoroughfares, and workmen of all kinds pursue their trades on the pavement. The Marina and the

Flora are the finest and most popular places of public resort. The former is a terrace 80 yards wide, extending for about a mile along the seaward side of the town in front of a range of palaces; and at its S. E. extremity is the Flora, a public garden, adorned with statues and fountains. The houses generally are built in the same style as those of Naples, with flat roofs, terraces, and Venetian blinds; they are divided into flats, each flat forming a distinct dwelling. The principal public edifice is the viceroy's palace, situated at the S. W. extremity of the town. It is an ancient irregular building, in various styles of architecture, and was formerly fortified; it contains a fine hall, a spacious court, a chapel built by King Roger in 1129, very rich in mosaics, a picture gallery, an armory, and an observatory. The cathedral is a Gothic structure of the 12th century, to which a modern dome has been added; the interior is supported by 80 pillars of oriental granite, and divided into a number of chapels, some of which are very rich, particularly that of St. Rosalia, the patroness of Palermo. This cathedral contains many mausolea in red porphyry, among them those of Roger, the Norman founder of the Sicilian monarchy, and the emperor Frederic II. The church *Del Gesu* is remarkable for its architecture and decorations, and that of the Capuchins for its vaults, in which the bodies of the dead monks are seen dried up, standing in niches in various attitudes with their garments on, some being 800 and 400 years old. There are many other churches, 40 monasteries, and 50 convents. The university of Palermo, founded in 1447, is in a declining state; it has a valuable collection of antiquities and a library of 40,000 volumes, but the number of students is small. Palermo is the see of an archbishop. The public charities consist of a principal and several minor hospitals, a foundling institution, and a lunatic asylum. The city has a supreme court of justice for the island of Sicily, a court of appeal for the province of which it is the capital, and a commercial tribunal. The chief manufacture of Palermo is in silk. Cottons, oil cloth, gold and silver articles, and hardware are also produced. The total value of exports in 1852 was \$3,498,720; of imports, \$3,080,415. The tunny fishery carried on from the town is very productive, and employs about 4,000 hands. Communication is kept up between Palermo and Naples both directly by sea, and through Messina and Reggio. In the neighborhood of the city there are many delightful villas. To the west is the royal mansion and park of *Bocca di Falco*, beyond which is the handsome Benedictine convent of *San Martino*. The *Monte Pellegrino*, an abrupt rocky mass to the N. W., is a striking feature in the landscape. It is famed for a cave or grotto to which St. Rosalia, a Norman princess, retired to lead a contemplative life; it is now a sanctuary, and an annual pilgrimage is made to it from Palermo in solemn procession on July 15.—Palermo was the earliest settlement of the

Phœnicians in Sicily, and became the chief seat of their power there. It was by the Greeks called Panormus, a name derived from the excellence of the anchorage near it. In 480 B. C. Panormus was the site of the first attempt of the Carthaginians on Sicily, from whence they were repulsed for nearly a century. It was taken by the Romans in the first Punic war, 254 B. C., and was a colony throughout the continuance of the empire. It fell into the hands of the Goths, was wrested from them by the Byzantine general Belisarius, and in A. D. 835 was taken by the Saracens; it was by them made the capital of the island, and retained the same dignity under the Norman kings, who in the 11th century drove out the infidels and founded the kingdom of Sicily. The court resided at Palermo until Sicily was united to the kingdom of Naples, when it was removed. The city has suffered much from earthquakes, and during a popular insurrection in 1848 was bombarded by the royal troops. In Oct. 1859, an attempted insurrectionary movement was easily suppressed. On April 4, 1860, another rising took place, and the streets of the city were the scene of a brave and desperate struggle between the populace and the royal troops. The insurgents were finally compelled to retire to the interior of the island. Garibaldi, having landed in Sicily May 13, entered Palermo on the 26th, conquering it after a protracted fight in the streets; and by convention the Neapolitan army evacuated the city on June 8, 1860, when it became the seat of the provisional government.

PALES, in Roman mythology, the tutelary deity of flocks and shepherds, holding nearly the same place in the religious worship of Rome that Pan held among the Greeks, and represented by some writers as a male and by others as a female. The festival of Pales, called *Palilia*, was celebrated on April 21, the anniversary of the foundation of Rome by Romulus. The principal rites were the purification of the stables, flocks, and herds by fire and smoke, and the offering of cakes, millet, and milk, followed by prolonged jollity and feasting.

PALESTINE (Gr. *Παλαιστίνη*, derived from the Heb. *Peleseth*, Philistia), a country of western Asia, now forming a part of the Turkish empire, bounded N. by the Lebanon mountains, which separate it from Syria, E. by the desert now called the Hauran, S. by a desert which separates it from Arabia and Egypt, and W. by the Mediterranean. It lies between lat. 30° 40' and 33° 32' N., and long. 33° 45' and 35° 48' E.; length about 200 m., average breadth 60 m.; area, 12,000 sq. m.; pop. estimated at 800,000. The country is now divided into the two pashalics of Acre and Gaza, and a part of it is included in the pashalic of Damascus. It is also subdivided into 7 districts, as follows: El Koda, including Jerusalem, Jericho, and about 200 villages; Hebron or El-Khaleel, embracing the S. part of Judæa; Gaza on the S. coast, with the towns

of Gaza and Jaffa; Lood, or the environs of ancient Lydda; Nabloos, or ancient Shechem (*Neapolis*) and Samaria; Areta, including Mt. Carmel and a part of the plain of Esdraelon; and Safed, nearly identical with ancient Galilee. Palestine is "a land of hills and valleys," or, as more minutely described in Deuteronomy (viii. 7-9), "a land of brooks of water, of fountains and depths that spring out of valleys and hills; a land of wheat, and barley, and vines, and fig trees, and pomegranates; a land of oil olive, and honey; a land wherein thou shalt eat bread without scarceness, thou shalt not lack any thing in it; a land whose stones are iron, and out of whose hills thou mayest dig brass." From the sea coast on the W. the land rises rapidly to a mountainous height in the centre, and declines on the other or E. side to the low level of the desert. The coast level varies very much in breadth, being in some places only a narrow pass between the mountains and the sea, and in others expanding into plains of considerable width. The southern portion of the coast level is termed in the Scriptures the plain or low country (Heb. *Shefelah*), and the western part of it was anciently the abode of the Philistines. It extends from Joppa to Gaza, and lies between the sea on the W. and the hills of Ephraim and Judah on the E. This plain is naturally very fertile. "Two parallel tracts," says Stanley, "divide the flat plain: the sandy tract (Ramleh), in which stand the maritime cities, and the cultivated tract, which presents for the most part an unbroken mass of corn, out of which rise here and there slight eminences in the midst of gardens and orchards, the seats of the more inland cities. . . . The most striking and characteristic feature of Philistia is its immense plain of corn fields, stretching from the edge of the sandy tract right up to the very wall of the hills of Judah, which look down its whole length from N. to S." Advancing N., these corn fields give place to a plain less level and less fertile, the Sharon of the Scriptures, a land of fine pastures, which under the Roman empire contained Cæsarea, the Roman capital of Palestine. Beyond Cæsarea the plain grows narrower, until it is terminated by Mt. Carmel, N. of which lies the plain of Acre, about 15 m. in length from N. to S., and about 5 m. in average breadth from the sea shore to the hills on the E. Mt. Carmel is a ridge 6 or 8 m. long and 1,500 feet high, stretching N. by W., and terminating at the sea in a high promontory which encloses on the S. the bay of Acre. North of Mt. Carmel are the Lebanon mountains, which consist of two parallel ranges running N. into Syria, and enclosing between them a beautiful and fertile plain, which is called in Scripture the valley of Lebanon, and by the classic writers was termed Coele-Syria, the "hollow or enclosed Syria." This plain, only the extreme southern portion of which is in Palestine, is 90 m. in length and about 11 m. in breadth, except at the S.

end, where it is narrower. The W. range of these mountains runs nearly parallel to the sea, into which it projects several promontories; and its average elevation is from 7,000 to 8,000 feet, while its loftiest summit, *Jebel-Makmel*, rises to the height of 12,000 feet, and is covered with perpetual snow. A little to the N. of *Jebel-Makmel* is the natural amphitheatre in which grow the few specimens that remain of the famous cedars that once covered all the mountains of Lebanon. This great western range was called *Libanus* by the classic writers, and to the eastern range they gave the name of *Anti-Libanus*. In the Scriptures both ranges are called Lebanon. They are each from 10 to 20 m. in breadth, and composed of masses of limestone rock. The southern part of the *Anti-Libanus* sinks in Palestine into the hills of Galilee, which rise from a table-land elevated about 1,000 feet above the sea, and sloping on the E. to the Jordan, on the W. to the plains of Acre, and on the S. to the plain of *Esdraelon*. The last named plain extends from E. to W. across the whole breadth of Palestine from the sea to the Jordan. It is often mentioned in the Scriptures under the names of *Megiddo*, *Jezreel*, and others, and was the great battle field of Jewish history. It is traversed by ridges known as the mountains of *Gilboa* and *Little Hermon*. On its N. E. border stands *Mt. Tabor*, which, though only 1,800 feet in height, is one of the most remarkable and interesting of the mountains of Palestine. About 6 m. S. of it is a hilly ridge which by some is supposed to be *Mt. Hermon*, though other writers maintain that *Hermon* was the loftiest peak of Lebanon. S. of the plain of *Esdraelon* stretches an unbroken tract of mountains, about 80 m. in breadth, and rising in height toward the S. till near *Hebron* it attains an elevation of 8,000 feet above the sea. The northern part of this region comprised *Samaria* and the southern *Judea*. The principal mountains of *Samaria* are *Ebal* and *Gerizim*, which rise to the height of 800 feet, the former on the N. and the latter on the S. of a narrow valley in which stands the town of *Nablos*, the ancient *Shechem*, the capital of the 10 tribes after their secession from the rest of Israel.—The hills of *Judea* are masses of barren rock, for the most part of moderate apparent elevation, though their general height above the sea is 2,000 or 3,000 feet. On their E. face these mountains descend abruptly to the great valley of the Jordan, the principal river of Palestine. The sources of the Jordan are on the southern declivity of the Lebanon mountains, and after a short course its head streams unite and flow into *Lake Merom*, now called *Lake Huleh*; after quitting this the river is sluggish and turbid for a short distance, till it passes over a rocky bed where its mud is deposited. Thirteen miles further on it enters the lake of *Tiberias* or *Gennesareth*, which is 620 feet above the sea. On issuing from the S. end of

this lake the river enters a valley from 5 to 10 m. wide, through which its course is so winding that within a space of 60 m. in length the river traverses 200 m. and descends 27 rapids. It finally enters the Dead sea after a total direct course from N. to S. of 120 m. At the mouth the river is 180 yards wide and 8 feet deep. Except the Jordan and its branches, the principal of which are the *Jarmuk* (the ancient *Hieromax*) and the *Jabbok* (now called the *Zerka*), Palestine has no streams considerable enough to be called rivers. Those which are so called in its history are mere brooks or torrents which become dry in summer. The *Kishon*, which enters the bay of Acre near *Mt. Carmel*, flows from *Mt. Tabor*, and in winter and spring is a large stream, while during the rest of the year it has water only in the last 7 m. of its course. The *Kanah* of Scripture is now the *Nahr-el-Kasab*, and enters the Mediterranean about 12 m. S. of *Cesarea*. The *Arnon*, often mentioned in Scripture, is now called the *Wady Modjeb*; it rises in the mountains of *Gilead* near *Katane*, and flows by a circuitous course of about 80 m. to the Dead sea. The brook *Kedron* flows through the valley of *Jehoshaphat*, on the E. side of *Jerusalem*, to the Dead sea, but is merely a torrent and not a constant stream. The principal lakes of Palestine are the Dead sea in the S. and the lake of *Tiberias* or sea of Galilee in the N.—In many parts of the country, and especially in the valley of the Jordan and the vicinity of the Dead sea, there are indications of volcanic origin and earthquakes are often felt. The mountains are mostly of oolitic limestone of a light gray color. Black basalt is very common. The general character of the scenery is stern and sombre. "As a general rule," says *Dr. Stanley*, "not only is it without the two main elements of beauty, variety of outline and variety of color, but the features rarely so group together as to form any distinct or impressive combination. Rounded hills, chiefly of a gray color—gray partly from the limestone of which they are all formed, partly from the tufts of gray shrubs with which their sides are thinly clothed, and from the prevalence of the olive—their sides formed into concentric rings of rock, which must have served in ancient times as supports to the terraces, of which there are still traces, to their very summits; valleys, or rather the meeting of these gray slopes with the beds of dry water courses at their feet; long sheets of bare rock laid like flag stones side by side along the soil; these are the chief features of the greater part of the scenery of the historical parts of Palestine. Above all other countries in the world it is a land of ruins. In *Judea* it is hardly an exaggeration to say that, while for miles and miles there is no appearance of present life or habitation, except the occasional goatherd on the hillside or gathering of women at the wells, there is hardly a hilltop of the many within sight which is not covered with the vestiges of some fortress or

city of former ages. The ruins we now see are of the most distant ages: Saracenic, crusading, Roman, Grecian, Jewish, extending perhaps even to the old Canaanitish remains before the arrival of Joshua."—Palestine has a mild and steady climate, with a rainy season in the latter part of autumn, winter and a dry and almost rainless season constituting the rest of the year. The heat of summer is oppressive in the low lands, but not among the hills; and the cold of winter is not sufficient to freeze the ground, though snow sometimes falls to the depth of a foot at Jerusalem. Though the mountains of Palestine have an exceedingly barren appearance, the soil of the plains and valleys is remarkably fertile. In ancient times even the mountains were cultivated by means of terraces; but in consequence of wars and the depopulation of the country, the terraces have been neglected and broken down, and the soil of the mountains swept by rains and torrents into the valleys. "No soil," says Schubert, "could be naturally more fruitful and fit for cultivation than that of Palestine, if man had not destroyed the source of fertility by annihilating the former green covering of the hills and slopes, and thereby destroying the regular circulation of fresh water which ascends as vapor from the sea to be cooled in the higher regions, and then descends to form the springs and rivers." There are now no forests in Palestine, and most of the trees of the country are of small size. The olive, the fig, and the pomegranate are largely cultivated, and are the most common trees. Beside these are the terebinth or turpentine tree, the oak, sycamore, mulberry, pine, pistachio, laurel, cypress, myrtle, almond, apricot, walnut, apple, pear, orange, and lemon. The number of shrubs and wild flowers is very great, and always attracts the attention of travelers; and there is such a prevalence of anemones, wild tulips, poppies, and other red flowers, as to give a scarlet color to the landscape. "Of all the ordinary aspects of the country," says Stanley, "this blaze of scarlet color is perhaps the most peculiar; and to those who first enter the Holy Land it is no wonder that it has suggested the touching and significant name of 'the Saviour's blood drops.'" Palestine has always been famous for its grapes, which are remarkable alike for size and flavor. The vine indeed was the national emblem of the Jews, and according to their traditions its primeval seat was at Hebron, where still the finest grapes are grown. The chief agricultural productions are wheat, barley, maize, and rye. Rice is grown on the marshy borders of the Jordan and some of the lakes. Peas, beans, and potatoes are cultivated, and also tobacco, cotton, and the sugar cane. More attention however is paid to pastoral pursuits than to agriculture, and flocks of sheep and goats are very numerous. Cattle are few and poor. The roads being impracticable for wheeled vehicles, camels are the principal beasts of burden.

Asses and mules are much used for riding, and fine Arabian horses are sometimes met with. The chief wild animals are bears, wild boars, panthers, hyenas, jackals, wolves, foxes, and gazelles. Lions, which were found here in ancient times, are now extinct. Birds are few in number, though there are many distinct species, among which may be mentioned the eagle, vulture, osprey, kite, hawk, crow, owl, cuckoo, kingfisher, woodpecker, woodcock, partridge, quail, stork, heron, pelican, swan, goose, and duck. Venomous serpents are unknown, and the most noxious animals are scorpions. Mosquitoes are common, and bees are extremely plentiful, depositing their honey in hollow trees and holes in the rocks. Locusts occasionally appear in vast swarms and devour every species of vegetation.—The present inhabitants of Palestine are a mixed race of very varied origin. In religion they are divided into Mohammedans, Christians, and Jews. The Mohammedans are the dominant and most numerous sect, and are composed of a few Turks who occupy the higher government situations, and of the great body of the common people, who are descended from mixed Arab, Greek, and ancient Syrian ancestors, the last element greatly preponderating. They are a noble-looking, graceful, and courteous people, but illiterate, fanatical, and indolent. The Christians are almost entirely of Syrian race, descendants of those who occupied the country when it was conquered by the Saracens. They belong mostly to the Greek church, of which there is a patriarch at Jerusalem, who has ecclesiastical jurisdiction over the whole of Palestine. Under him are 8 bishops, whose sees are Nazareth, Acre, Lydda, Gaza, Sebaste, Nablous, Philadelphia, and Petra. There are also a few Maronites and Roman Catholics in the large towns, and in Jerusalem a few hundred Armenians under a patriarch of their own faith. The Jews are about 10,000 in number, and live almost exclusively in the cities of Jerusalem, Hebron, Tiberias, and Safet. They are of foreign origin, mostly from Spain, and a few from Poland and Germany. In dress, manners, customs, and general appearance, the natives of Palestine preserve to a remarkable degree the peculiar characteristics of primitive oriental life, as it is described in the Scriptures. "No European nation," says Mr. Porter in Murray's "Handbook of Syria," "with the exception perhaps of the Spaniards, bears the least resemblance to them. Like Spain, too, the best specimens of humanity are here found among the lower classes. The further we go from the contaminated atmosphere of government offices, the more successful shall we be in our search after honesty, industry, and genuine patriarchal hospitality—the great, almost the only unadulterated virtue of the Arab. They are illiterate of course, and extremely ignorant of all Frank inventions; but still there is a native dignity in their address and deportment, which will both please and astonish those who

have seen the awkward vulgarity of the lower classes in some more favored lands. Whether we enter the tent of the Bedawy or the cottage of the fellah, we are received with an ease and courtesy that would not disgrace a palace. The modes of salutation are very formal; perhaps some would call them verbose and even tedious. The gestures used in salutation are also graceful, if a little complicated. The touching of the breast, the lips, and the forehead with the right hand, seems to say that each one thus saluted is cherished in the heart, praised with the lips, and esteemed with the intellect. When peculiar deference and respect are intended to be shown, the right hand is first lowered almost to the ground, as a proof that the individual would honor your very feet, or the soil you tread. A still greater deference is implied in kissing the hand; and the greatest of all is kissing the feet." Dr. Olin, an American traveller, says: "The people are commonly temperate and frugal, which may be denominated oriental virtues. Their situation, with regard to the physical means of comfort and subsistence, is in many respects favorable, and under a tolerable government would be almost unequalled. As it is, the Syrian peasant and his family fare much better than the laboring classes of Europe. The mildness of the climate, the abundance of land and its fertility, with the free and luxuriant pasturage that covers the mountains and the plains, render it nearly impossible that the peasant should not be well supplied with bread, fruit, meat, and milk. The people almost always appear well clothed. Their houses, too, though often of a slight construction and mean appearance, must be pronounced commodious when compared with the dark, crowded apartments usually occupied by the corresponding classes in Europe." With all these advantages, however, the population of Palestine is less than $\frac{1}{10}$ of what it was in ancient times, its increase being checked by polygamy and the oppression of the government, which renders property insecure and thus discourages industry.—Palestine was first known as Canaan, from the 4th son of Ham, from whom its inhabitants were supposed to be descended. This name, however, was confined to the country between the Mediterranean and the Jordan, the principal region E. of that river being called the land of Gilead. Palestine was subsequently called the land of promise, the land of Israel, Judah, Judæa, and the Holy Land. The term Judæa, though in later periods of Jewish history frequently applied to the whole country, belonged, strictly speaking, only to the southern portion of it. In the earliest times in which Palestine or Canaan becomes known to us, it was divided among various tribes, who were by the Jews called collectively Canaanites. The precise locality of these nations is not in every case distinctly known. The Kenites, the Kenizzites, the Kadmonites, and a part of the Amorites lived E. of the Jordan, while W. of that river dwelt the

Hittites, the Perizzites, the Jebusites, and most of the Amorites, in the hill country of the south; the Canaanites proper, in the middle; the Girgashites, along the E. border of the lake of Gennesareth; and the Hivites, mostly in the N. among the mountains of Lebanon. The southern part of the coast was occupied by the Philistines and the northern by the Phœnicians. After the conquest of Canaan by the Israelites under Moses and Joshua, 15 centuries B. C., the land was distributed among the tribes. Judah, Simeon, Benjamin, and Dan occupied the south; Ephraim, half of Manasseh, and Issachar the middle; and Zebulon, Naphtali, and Asher the north. Reuben, Gad, and the other half of Manasseh were settled beyond the Jordan. After the division into two kingdoms by the secession of the 10 tribes, the boundary line between them was the northern limit of the tribe of Benjamin. In the time of Christ Palestine was subject to the Romans, and the country W. of the Jordan was divided into the provinces of Galilee, Samaria, and Judæa. Galilee was that part of Palestine N. of the plain of Esdraelon, and was divided into lower or southern and upper or northern Galilee. Samaria occupied nearly the middle of Palestine; but although it extended across the country, it did not come down to the sea shore. Judæa as a province corresponded to the N. and W. parts of the ancient kingdom of that name; but the S. E. portion formed a part of the territory of Idumæa. On the other side of the Jordan the country was called Peræa, and was divided into 8 districts, viz.: 1, Peræa in a limited sense, which was the southernmost district, extending from the river or brook Arnon to the river Jabbok; 2, Gilead, N. of the Jabbok; 3, Decapolis, or the district of 10 cities, which, as nearly as can be ascertained, were Scythopolis or Bethshan, which however was on the W. side of the Jordan, Hippos, Gadara, Pella, Philadelphia or Rabbah, Dion, Canatha, Galasa, Raphana, and perhaps Damascus; 4, Gaulonitis, extending to the N. E. of the upper Jordan and of the lake of Gennesareth; 5, Batanea (Heb. Bashan), E. of the lake of Gennesareth; 6, Auranitis, called also Iturea, N. of Batanea and E. of Gaulonitis, now known as the desert of Hauran; 7, Trachonitis, extending to the N. of Gaulonitis and E. from Paneas and the sources of the Jordan, where it was separated from Galilee; 8, Abilene, in the extreme N., among the mountains of Anti-Libanus.—Palestine remained subject to the Roman and Byzantine emperors for more than 6 centuries after Christ. The Jews, after frequent rebellions, in one of which, A. D. 70, Jerusalem was destroyed by Titus, were mostly driven from the country and scattered as slaves or exiles over the world. With the spread of Christianity, Palestine became the resort of vast numbers of pilgrims, and Jerusalem was made the seat of a patriarch. The emperor Constantine and his mother Helena erected throughout the land costly memorials of Christian

faith, marking with churches, chapels, or altars every spot supposed to have been the scene of the acts of the Saviour. In 610 the Persians under Chosroes invaded Palestine, and, assisted by the Jews to the number of 26,000, succeeded in capturing Jerusalem. It was regained by Heraclius in 622, but was conquered by the Mohammedan Arabs in 637. For the next two centuries the country was the scene of civil war between the rival factions of the Ommyiade, the Abbasside, and the Fatimite caliphs. From the middle of the 8th century it was a province of the Abbasside caliphs of Bagdad till 969, when it fell under the power of the Fatimite rulers of Egypt. In 1073 it was conquered by the Seljookian Turks, but in 1096 it was regained by the Egyptian sultans, in whose possession it was when invaded by the crusaders in the following year. The crusaders made Godfrey of Bouillon king of Jerusalem, and he and his successors reigned in Palestine till Jerusalem was retaken by Sultan Saladin in 1187, and the Christian kingdom overthrown. Two years afterward another crusade was undertaken under Philip, king of France, Richard I. of England, and the emperor Frederic Barbarossa of Germany. It did not succeed in regaining Jerusalem, but partially restored the Christian rule upon the coast. Another crusade in 1216, chiefly of Hungarians and Germans, met with little more success. Still another, undertaken by the emperor Frederic II. in 1228, succeeded in recovering Jerusalem, and the Christian dominion was reestablished over a considerable extent of territory; but after various vicissitudes of fortune, and in spite of repeated succors from Europe, it at length finally yielded to the arms of the Egyptian Mamelukes in 1291. The sultans of Egypt held it till 1517, when it was conquered by the Turks, in whose possession it has remained till the present time, with the exception of a brief occupation in 1839, '40, and '41 by the forces of the rebellious pasha of Egypt, Mehemet Ali.—See Ritter, *Die Erdkunde* (vols. xiv.-xvii.); Schubert, *Reise nach dem Morgenlande* (1838-'40); Robinson, "Biblical Researches" (Boston, 1841-'52); Olin, "Travels in the East" (New York, 1843); Kitto, "Palestine" (London, 1841); Lord Lindsay, "The Holy Land" (London, 1839-'58); W. C. Prime, "Tent Life in the Holy Land" (New York, 1857); W. M. Thomson, D.D., "The Land and the Book" (New York, 1859).

PALESTRINA, GIOVANNI PIETRO ALOISIO DA, an Italian composer, born in Palestrina, the ancient Praeneste, near Rome, in 1524, died in Rome, Feb. 2. 1594. In 1551, having gained some distinction as a composer of music, he was admitted among the singers of the pontifical chapel, and a few years later was made chapelmaster by Pope Julius III., to whom he had dedicated 4 masses for 4 voices. In 1555 he was dismissed from office by Paul IV., on account of his having quitted the state of celibacy, and for a number of years he occupied

successively the position of chapelmaster at the churches of St. John Lateran and Sta. Maria Maggiore. In 1571 he was appointed chapelmaster of St. Peter's, and shortly after maestro to the congregation of the Oratory, both of which offices he retained during the remainder of his life. He was essentially a composer of church music, in the character of which he effected an important reform. The subject of the improvement of ecclesiastical music having been referred by the council of Trent to a committee of cardinals and chaplain singers, a discussion arose respecting the retention or rejection of the secular tunes which then formed the principal themes of most masses and psalms. Palestrina, being called upon to compose a work written in a more severe, simple, and devotional style, as a means of contrasting the two kinds of music, produced his celebrated "Mass of Pope Marcellus," the performance of which caused so profound a sensation that the pope is said to have likened it to the heavenly melodies which St. John heard in his apocalyptic vision. This work formed the model for compositions of its class, and raised Palestrina so high in the estimation of professors of his own time, that two years before his death a collection of psalms in 5 parts was published and dedicated to him by 14 of the greatest contemporary masters of Italy. His music, consisting chiefly of masses, psalms, motets, and madrigals, is grave and learned; and some of that written for the church, when heard in its proper place and under favorable circumstances, affects the mind with emotions of tenderness and awe. The composition exhibits more of the skilful employment of fugues, canons, and imitations, than of genuine inspiration; but the majesty and strength of the melodies, and the intelligent distribution of the vocal parts, must always command the admiration of the musician, notwithstanding that the learning of the composer would fail to be appreciated in the modern concert room. The science of counterpoint, in its infancy in Palestrina's time, was brought by him to a considerable degree of perfection, and to his genius was due the development and classification of the musical ideas which had germinated during many previous ages. He is probably the only composer of the 16th century whose works will survive the vicissitudes of his art. A *Stabat Mater*, and specimens of his masses, motets, and madrigals, have been published by A. E. Choron, but the greater part of his works are to be found only in the large libraries of Europe. Some of his masses and motets are still employed in the service of the Roman Catholic church, and 3 of his motets adapted to versions of the Psalms are in use in the English cathedral service. He was buried in St. Peter's, whither his remains were attended by an "infinite concourse of people," and during the funeral service the *Libera me Domine* was sung. The abbaté Baini has published "Memoirs of the Life and Works of Palestrina" (2 vols. 4to., Rome, 1828).

PALESTRO, a town of Piedmont, on the E. bank of the Sesia, 8 m. S. E. from Vercelli, famous for a battle between the Sardinians and Austrians, May 31, 1859. The Austrians had occupied a strong position on the E. bank of the river, and the Sardinians, commanded by King Victor Emanuel, moving from Casale, had made two unsuccessful attempts to cross it, one above Vercelli, and the other at Candia. At Palestro, midway between the two, the effort was renewed. The king on the 30th crossed with Gen. Cialdini's division, and finding the Austrians intrenched drove them back after an obstinate struggle at the point of the bayonet, capturing 2 guns and making a number of prisoners. On the following morning the Austrians, 25,000 strong, attacked the victors and endeavored to retake the village. They were met by the king in person at the head of the 4th division, and Gen. Cialdini commanding the cavalry and the 8d regiment of French Zouaves. The contest was long and violent. The Sardinians, after keeping the defensive for a time, finally repulsed the enemy on his whole front, but were then for a moment outflanked upon the right wing, where there was a bridge of boats across the Sesia, over which Gen. Canrobert was to effect a junction with the king. The Zouaves, unsupported by any artillery, were immediately despatched to save this post, and, rushing upon the Austrian battery planted on the further side of a deep canal, captured 5 guns, made 500 of the Austrians prisoners, and drove 400 into the canal. Three guns and nearly 1,000 prisoners were taken in other parts of the field; and the Austrians then withdrew, to plan a fresh attack for the same evening. It was repulsed, however, and the following morning (June 1) the allies entered Novara.

PALEY, WILLIAM, an English divine and author, born in Peterborough in July, 1743, died May 25, 1805. He was yet a child when his father removed to Giggleswick, Yorkshire, having been appointed curate of the parish and teacher of the grammar school there. He was educated at home, displaying superior capacity, till in his 16th year he was entered as sizar at Christ's college, Cambridge, his father prophesying at his departure his future eminence, saying: "He has by far the clearest head I ever met with." As a boy he was physically sluggish, disliked athletic sports, and he relates that on his first journey to the university he fell from his pony 7 times. Noted at first for his social habits and qualities, he applied himself diligently to study from his 8d collegiate year, and became senior wrangler on taking his bachelor's degree in 1768. After teaching for 8 years he returned to his college as fellow, became one of the tutors, lectured on moral philosophy and divinity, and was intimate with Mr. Law, afterward bishop of Carlisle, by whom he was presented in 1775 to the rectory of Musgrove in Westmoreland. He then married and retired from the university to his living. He was soon inducted into the vicarage of Dalston in

Cumberland, and advanced successively to the living of Appleby in Westmoreland, to a prebendship in Carlisle cathedral, and in 1783 to the archdeaconry of Carlisle. In 1785 appeared his first important work, "The Principles of Moral and Political Economy," of which his lectures at Cambridge had been a general sketch. He received for the copyright £1,000, an unusually liberal payment, which was justified by the popularity of the work. He published his "Horæ Paulinæ" in 1790, the most original and ingenious of his writings, bringing reciprocal supports to the genuineness of St. Paul's Epistles and of the Acts of the Apostles from the undesigned coincidences between them. During the alarm caused by the French revolution in 1791 he produced his "Reasons for Contentment," and received the vicarage of Addingham; and two years later he exchanged the benefice of Dalston for that of Stanwix. In 1794 appeared his "View of the Evidences of Christianity," and 3 additional preferments were immediately conferred on him, one of them, the rectory of Bishop-Wearmouth, being worth £1,000 per annum. The freedom of some of his essays on government, and perhaps also a supposed deficiency in personal dignity in consequence of his homely manners and conversation, prevented his appointment by the court to the bench of bishops. Being made sub-dean of Lincoln, he took his doctor's degree, and addressed the clergy on the dangers and temptations which "beset the clerical character." In 1795 he changed his residence to Bishop-Wearmouth, and consented to act in the commission of peace; in 1800 was attacked by the painful nephralgic disease which ultimately proved fatal; and in 1802 published his "Natural Theology," which he had prepared in the intervals of suffering. He passed his life in the quiet performance of his duties, strictly and regularly dividing his time, enjoying the society of his friends, and mingling familiarly with his neighbors in their labors and recreations. He was fond of angling, spent an hour in his garden twice a day, and read books of amusement for an hour at each of his meals. The mind of Paley was preëminently practical, and it was by practical issues that he estimated religion and philosophy. Few writers have so felicitously and ingeniously investigated and illustrated facts and the inductions from facts. In his own province he grasps all the bearings of a subject, and follows out an argument with unsurpassed minuteness and force. His style is peculiarly simple, clear, and precise, abounding in apt and homely illustrations, and succeeded in popularizing the most recondite knowledge. It has more than any other merit contributed to the permanent reputation of his works. His ethical theory, which underlies his "Moral and Political Philosophy," denies the existence of a moral sense or any original moral constitution of human nature, and makes the expectation of future reward or punishment the only motive of virtuous action. Whatever is

expedient is right. Utility is the ground of obligation, but it must be determined with reference to remote as well as direct efforts, to eternity as well as time. Applying this principle to politics, he makes the "will of God as collected from expediency" the ground of civil obedience. If an illegitimate government have become peaceably established so that it advances the good of the subjects, public utility requires that it should be obeyed. On the other hand, if a legitimate government from corruption or neglect is injurious to the public welfare, it should be overthrown. He affirms that the "divine right of kings is on the same footing with the divine right of constables," namely, the law of the land. "The final view," he says, "of all natural politics is to produce the greatest amount of happiness." Expediency prevails even in his view of religious establishments, no one form of which, he contends, is inculcated in the New Testament or is a part of Christianity. The authority of the church is founded on its utility, and therefore the tests and restrictions should be as few and simple as possible. In his view of the "Evidences," the miracles attest the revelation. The reality of the miracles depends on the testimony of the apostles, who profess to have been witnesses of them. The credibility of these witnesses is inferred, first, from the fact that they could not have been deceived as to such occurrences, and, secondly, "that they passed their lives in labors, dangers, and sufferings, voluntarily undergone in attestation of the accounts which they delivered, and solely in consequence of their belief in these accounts; and that they also submitted, from the same motives, to new rules of conduct." They would not thus have suffered and struggled for a lie from which no advantage was to be obtained, when by keeping silent they would have escaped enmity, pain, and death. His greatest work is his "Natural Theology," designed to demonstrate the existence and perfections of God from the evidences of design in the adaptations of nature. He draws his illustrations from familiar objects, especially from animal mechanism, and the argument is strengthened with every new example. The divine power, wisdom, and especially benevolence are thus demonstrated. The proof is entirely *a posteriori*, no appeal being made to man's moral instincts or *a priori* ideas. He does not even inquire into the grounds of belief, the principles which lead the mind to infer intelligence from the evidences of order, but rests satisfied with the fact that it is inevitable for the mind to do so. The work is remarkable for the happy selection of its materials and the rare beauty of its style, and is as interesting as it is convincing. An annotated edition by Lord Brougham and Sir Charles Bell was published in 1836, in 2 vols. 8vo., to which were added by the former in 1839 "Dissertations on Subjects connected with Natural Theology," in 2 vols., and a "Discourse of Natural Theology,"

in 1 vol. (abridged in Knight's shilling volumes, 4 vols., 1853). It was first pointed out in 1848 that the general argument and many of the illustrations of Paley were borrowed without acknowledgment from a Dutch work by Nieuwenhuyt, which was published in English under the title of the "Religious Philosopher" in 1718-'19. Yet the impress of Paley's mind and his peculiar literary skill mark his own work throughout. It has been suggested that he made it up, as he did most of his other writings, from the notes taken for his lectures while at Cambridge; that no name was entered with these notes; and that at the time of the final writing he would have been unable to find his original authorities, even if he were aware of his obligation to another. In the preface of another work he remarks: "My method of writing has constantly been this, to extract what I could from my own stores and my own reflections in the first place; to put down that, and afterward to consult upon each subject such readings as fell in my way. . . . I make no pretensions to perfect originality." Beside the above named works, he was the author of various sermons and tracts. In 1789, when the first great discussion in the house of commons on the abolition of the slave trade was expected, he wrote a short treatise entitled "Comments against the Unjust Pretensions of Slave Dealers and Holders to be indemnified," and sent it to the committee. A complete edition of his works was edited by his son, the Rev. Edmund Paley (4 vols., London, 1838). The best biography is that by Meadley (Sunderland, 1809).

PALFREY, JOHN GORHAM, D.D., LL.D., an American clergyman, politician, and author, born in Boston, Mass., May 2, 1796. He received his early education at the school of Master Payne in Boston, and at Phillips academy in Exeter, and was graduated at Harvard college in 1815. He studied theology, and was ordained June 17, 1818, as minister of the Congregational church in Brattle square, Boston, in which office he succeeded Edward Everett. In 1831 he was appointed to the Dexter professorship of sacred literature in the divinity school of Harvard university, previously filled by Andrews Norton, and removed to Cambridge, where he has ever since resided. In Oct. 1835, in addition to the laborious duties of his office, he assumed the editorship of the "North American Review," which he conducted till the autumn of 1842. He resigned his professorship in 1839, and from that period virtually retired from the pulpit. In the same year he delivered before the Lowell institute in Boston a series of lectures upon the "Evidences of Christianity," which were afterward published (2 vols. 8vo., Boston, 1848). This work was followed by "Lectures on the Jewish Scriptures and Antiquities" (4 vols. 8vo., 1838-'52). He had previously published "Harmony of the Gospels" (12mo., 1831), "Sermons" (1834), and "Academical Lectures" (1838), beside at various times sermons upon

important occasional topics, and in 1839 a 4th of July oration delivered before the city authorities of Boston. In 1844 he was appointed by the governor of Massachusetts secretary of state, which office he filled for several years to the general satisfaction of the public. In 1847 he took his seat in congress as a representative, having been elected by the whigs of the Middlesex district of Massachusetts. He had avowed decided anti-slavery opinions, and had given a practical manifestation of his views by liberating and providing for a number of slaves who had fallen to his share in an inheritance from a deceased relative in New Orleans. In 1846 he had contributed to the "Boston Whig" a series of articles upon the "Progress of the Slave Power," which exerted much influence upon public sentiment in New England, and were afterward collected in a volume. At the organization of the 80th congress he refused on anti-slavery grounds to vote for Robert O. Winthrop of Massachusetts for speaker, and thus drew upon himself the censure and opposition of that portion of the whig party which was opposed to the anti-slavery movement. His reelection to congress was contested with unusual pertinacity, and after 17 successive elections without a choice, he was defeated. He had now become one of the acknowledged leaders of the free soil party, and one of its most popular speakers and writers. In 1851 he was one of the editors of the "Commonwealth" newspaper, the principal free soil journal of New England; and in the same year was the candidate of his party for the office of governor, but was defeated, and soon after retired from public life. In 1852 he published "A Review of Lord Mahon's History of England," and in 1854 "Remarks on the proposed Constitutional Amendments" and "The Relation between Judaism and Christianity." He now began to devote himself to a task he had long contemplated, of writing a history of New England, to which he has since given undivided and laborious attention. To collect materials for his work, in 1856 he went to Europe, to which he had made a previous visit in 1825, and at the end of two years published the first volume of his "History," which immediately took a high rank in American historical literature by its thorough research, its original views (as for instance on the character of the aborigines), and its attractive and classical style. A second volume appeared in the latter part of 1860, bringing the history down to 1667, and several more volumes are to follow.

PALGRAVE, SIR FRANCIS, an English antiquary and author, born in London in 1788, of a Jewish family named Cohen, which name he exchanged for that of Palgrave. He first became known as the editor of the "Parliamentary Writs" (4 vols. fol.), published by the commissioners of public records in 1827 and 1834. During the progress of this work he was admitted to the bar at the Inner Temple in 1827. In 1831 he published a pamphlet

on "Conciliatory Reform" and a "History of England: the Anglo-Saxon period," in Murray's "Family Library." About the same time he was elected fellow of the royal society and of the society of antiquaries. In 1832 he was knighted "for his general services and his attention to constitutional and parliamentary literature." His "Rise and Progress of the English Commonwealth" (2 vols. 4to., 1832) is devoted to the Anglo-Saxon polity and manners, and is especially valuable to the student of English jurisprudence. In the following year he was appointed by the king one of 20 commissioners to inquire into the existing state of the municipal corporations of England and Wales; but dissenting from the report of the majority of the commission, he presented his own views in a "Protest" (1835). He was soon afterward appointed deputy keeper of her majesty's public records, an office which he still holds. He has published, beside the works already mentioned, *Rotuli Curia Regis* (2 vols. 8vo., 1835); "Calendars and Inventories of the Treasury of the Exchequer" (3 vols. 8vo., 1836); "Documents illustrating the History of Scotland" (1837); "Truths and Fictions of the Middle Ages—the Merchant and the Friar" (1837); and an "Essay upon the Authority of the King's Council" (8vo., 1844). He is now engaged on a "History of Normandy and England," vols. i. and ii. of which appeared in 1851-'7. He also wrote the 1st edition of Murray's "Handbook to North Italy," and was for many years a constant contributor to the "Quarterly Review" of some of its best known articles on mediæval literature, arts, and institutions, of which his knowledge is profound and extensive.

PALIMPSEST, a term applied to a parchment from which one writing has been erased, to make room for another. The practice of utilizing vellum MSS. in this manner existed among the ancients, but came into much more common use during the dark ages, owing to the great scarcity of writing materials. This was felt earlier in the western than in the eastern empire, as the former was first cut off from obtaining a supply of papyrus from Egypt; and in consequence the Greek palimpsests are found to date back no earlier than the 11th century, while the Latin go back as far as the 8th and even the 7th. In some palimpsests the original writing has been so poorly effaced, that it can be read by a practised eye; for the deciphering of others powerful chemical applications and the use of magnifying lenses are required. A considerable number of palimpsests containing portions of the Septuagint and New Testament have been brought to light; but in classical literature the investigation has been attended by more important results, fragments of Greek and Roman classics supposed to be lost having been recovered, and a promise given of still more valuable fruits when a fuller investigation shall have been made. The first edition of a fragment of a classic author recovered from a pa-

palimpsest was brought out in 1773 by Paul James Bruns, who found in a rescribed manuscript of the Vatican collection a fragment of the 91st book of Livy. The great explorer in this department, however, was Cardinal Angelo Mai, who recovered the lost work of Cicero *De Republica*; and similar investigations were prosecuted by Niebuhr, who recovered from a palimpsest manuscript in the library of the chapter of Verona a fragment of the Institutes of the Roman jurist Gaius. Among the latest discoveries are portions of the 1st, 11th, 18th, and 15th books of Pliny, which were found by Dr. Fridegar Mone in a Benedictine monastery in Carinthia, in 1854; fragments of the Iliad of Homer from a Syrian palimpsest, amounting in all to 3,873 lines; and from a palimpsest of a similar kind fragments from the history of Gaius Gracchus Licinianus, an author who flourished about the beginning of the Christian era. The last was published by Karl Pertz in 1857.

PALINURUM, a promontory of Lucania in Italy, on the Tyrrhenian sea, about half way between Velia and Buxentum; lat. 40° N., long. 15° 15' E. It derived its name from the tradition recorded by Virgil, that it was on this spot that Palinurus the pilot of Æneas was buried. Near this promontory, during the 1st Punic war, 258 B. C., a Roman fleet under the consul Servilius Cæpio and Sempronius Blæsus was wrecked and 150 vessels lost; and again in 86 B. C. a portion of the fleet of Augustus was lost on the coast between Velia and Palinurus Portus, a harbor formed by the cape, and now called Porto di Palinuro.

PALISADES, or **PALISADOES**, in fortification, a barrier made of posts set in the ground close together, sharpened at the top, and standing about 10 feet high.—The term has been applied to cliffs of vertical columns of trap rock, and especially to those which present a conspicuous feature in the scenery of the Hudson river, extending from Fort Lee along the New Jersey shore to the N. line of the state, in one unbroken precipitous wall of more than 20 m. in length. The wall rises a considerable part of the way directly from the river, along the edge of which is a talus of fragments of the trap which have fallen from above. These, however, have within the last few years been very largely removed for paving the streets of New York, and the cliffs themselves are now quarried for furnishing more stone for this purpose. The height of the range near Weehawken is about 810 feet above the river, and from this it gradually rises to 540 feet near the state line; but the Palisades themselves do not generally attain the full height of the narrow trap belt. The range continues near the river in bold rocky bluffs to Haverstraw just below the highlands. There it curves back from the river to the N. W. and W., presenting again high columnar escarpments 800 to 800 feet high facing toward the N. Below Hoboken the range continues S., forming the ridge back of

Jersey City, and disappearing at Bergen point. On the extension of its line the rock appears again, forming a smooth ridge on Staten island, which is covered with soil. In it are the quarries that furnished the Russ pavement, which, though of greenstone, has gone by the name of granite. This remarkable belt of trap is a dike forced up through the red sandstone formation, some of the strata of which are seen at the base of the cliffs penetrated by the trap and dipping toward the W. In the valley on the W. side of the dike the red sandstone is the prevailing rock formation. In width the dike varies from $\frac{1}{4}$ of a mile to more than a mile, and in some portions of its range it is repeated in several parallel ridges. On the W. side the slope is gentle.

PALISSY, BERNARD, a French potter, born near Agen about 1510, died in Paris in 1589. He was first employed, as we learn from himself, in "portraiture and vitrification," which probably means that he painted on glass; and being acquainted with geometry, he was occasionally employed in surveying and the drawing of maps. In 1539, having seen some ornamented pottery from Italy, he applied himself to discover the method of enamelling which had been brought to such a degree of perfection in that country. To this he devoted his whole life, regardless of expense, labor, disappointment, and hardship; he reduced himself and family to poverty rather than give up his undertaking, and finally succeeded after 16 years of untiring exertion. Having in the mean time become a Protestant, he was imprisoned at Bordeaux during the reign of Henry II.; but through the intervention of some of the nobility, among others the great constable de Montmorency, who employed him in decorating his castle at Ecouen, he was released, and even appointed "maker of the king's rustic potteries" (*rustiques agulines*), and resided in the Tuileries, so that he was styled "Bernard des Tuileries," and by some "governor of the Tuileries." Here he improved his discovery, and manufactured earthen figures and ornaments, which in artistic perfection rivalled those of Faenza or Castel Durante. These were generally used in the decoration of castles and palaces. His lesser works, such as vases, jugs, ewers, and salvers, were eagerly sought for, and are still highly valued. Meanwhile he was engaged in scientific pursuits, and it has been appropriately said that he was to chemistry what Lord Bacon was to philosophy, and that his *Traité de l'art de terre* is the *Nooum Organum* of the science. In his other treatises, *De la marnie*, *De la nature des eaux et fontaines*, &c., anticipating modern scientific discoveries, he expounded a method of taking soundings, and gave the theory of Artesian wells and stratifications. In 1575 he delivered a course of lectures on his discoveries, and invited all his hearers to propose questions and objections. Many scholars and scientific men accepted this challenge, the celebrated surgeon Am-

broise Paré among the number. During the massacre of St. Bartholomew's day, Palissy was saved by Catharine de' Medici; but toward the end of the reign of Henry III. he was again involved in serious difficulties on account of his religion. Probably through the enmity of the leaguers, he was arrested and confined in the Bastille, where he died. The name of Palissy, scarcely noticed by his contemporaries and completely ignored during the 17th century, was brought again to light by Fontenelle, Buffon, and others, who pointed out the value of his scientific researches. An edition of his works was published in 1777 by Faujas de St. Fond and Gobet, and a better one in 1844 by A. Cap (Paris). J. Salles has written an *Étude sur la vie et les travaux de B. Palissy* (8vo., Nîmes, 1855), and his life has also been written by H. Morley (London, 1852). Specimens of his art are preserved in the museums of the Louvre, of Sèvres, of the Cluny hotel in Paris, and of the Favorite near Munich.

PALLADIO, ANDREA, an Italian architect, born in Vicenza, Nov. 30, 1518, died there, Aug. 6, 1580. He derived the principles of his art from the writings of Vitruvius and Alberti, and previous to his 30th year made 8 journeys to Rome, where he took careful drawings and measurements of the principal ancient edifices. Establishing himself in Vicenza, he was first brought into notice by his design for the *loggie* or open porticos surrounding 3 sides of the Palazzo della Ragione, immediately after the completion of which he was summoned to Rome by Paul III. to give his advice respecting the works then in progress at St. Peter's. The pope dying before Palladio's arrival, his mission seems to have been without any important result; but after his return to Vicenza he was for many years busily employed in the construction of villas and private mansions there and along the banks of the Brenta. In these were developed the composite Italian style called the Palladian, which is still one of the most popular in architecture. The most famous of them is the Rotonda Capra, known as Palladio's villa, just outside of Vicenza, of which Goethe said: "It may be that architecture never pushed splendor to a higher pitch." Like most of the structures in the neighborhood of Vicenza erected by him, it has suffered so severely from neglect and abuse as to give no just idea of the merits of the original design. The rising fame of Palladio caused him in time to be invited to Venice, where he designed two churches, that of San Giorgio Maggiore, commenced in 1556, but not completed until 1810, and that known as Il Santissimo Redentore, the latter of which is considered one of his finest works. He also designed the atrium for the convent Della Carità and the façade of San Francesco della Vigna. He subsequently passed some time at the court of Emanuel Philibert, duke of Savoy, who paid him distinguished honors. Among other important works by him were the magnificent Palazzo Barbaro at Maser in the Trevi-

giano, and a palace at Montagnana for Francesco Pisano. His last work was the Teatro Olimpico at Vicenza, the most curious structure designed by him, and which has been the subject of very conflicting criticisms. It was not finished until after his death. His merits as an architect have been as much overrated by such admirers as Goethe, Quatremère de Quincy, Hope, and Beckford, as they have been ignored by others; but the errors and inconsistencies pointed out in his designs are not in all cases his own, many buildings attributed to him having been varied in the execution, or designed by others. The charm of the Palladian style has been said "to consist entirely in a certain justness of proportion with which Palladio has distributed all the parts of his architecture; the basement being neither too high nor too low for the order above it; the windows of the right size and well spaced; and all the parts and proportions suited to one another. The same excellence is found in his orders, and the relation of the columns, capitals, entablatures, &c. He has not adopted the theoretical rules of another, but has drawn them all from what he felt to be pleasing to himself, and suited to his own style of art; but they are not good when united to a more solid and less ornamental manner." (Wood, "Letters from an Architect.") He wrote a treatise on architecture (fol., Venice, 1570), which has several times been reprinted in very costly style, and a small work entitled *La antichità di Roma*, which appeared after his death.

PALLADIUM, a wooden image of Pallas or Minerva, which is said to have been thrown down to earth by Jupiter. It fell in the neighborhood of Troy, where Ilius the founder of that city, who had just prayed for favorable omens, regarding it in that light, took possession of it and built for it a sanctuary. It was a tradition that Troy could never be taken while this image remained in the city, and therefore Ulysses and Diomedes were commissioned to steal it, and succeeded in the undertaking. Other accounts state that the palladium was carried to Italy by Æneas, and in that country the cities of Rome, Lavinium, Luceria, and Siris claimed to possess it. Several cities of Greece also pretended to have this image.

PALLADIUM (symbol Pd, chemical equivalent 58.24), a metal discovered in 1808 by Wollaston. With a number of other metals it is contained in native platinum, and sometimes constitutes 1 per cent. of the mixture. It also occurs with the gold of Brazil and in combination with selenium in the Hartz. It is separated from the platinum sand by dissolving this in *agua regia*, expelling the excess of acid by evaporation, and then adding a solution of cyanide of mercury until precipitation ceases. The palladium is the only metal thrown down; it is in the form of a bright yellow powder, which when heated to redness becomes pure palladium. This metal is grayish white, having much resemblance to platinum in color and lustre. It is both ductile and malleable, is

harder and more fusible than platinum, and of specific gravity 11.3 to 11.8. Being rarely obtained, it is little employed for useful purposes. Beams of delicate balances and nicely graduated scales of instruments have been made of it, for which purpose it is well adapted on account of its unchangeable character when exposed to the action of the atmosphere and of sulphuretted hydrogen. It has also been employed by dentists as a substitute for gold in fastening artificial teeth. When at a red heat and submerged in oxygen gas, its surface acquires a fine blue color by slight oxidation. By nitric acid it is oxidized and dissolved. Its alloys with silver, iron, tin, lead, arsenic, and bismuth are fusible and brittle; with gold hard and white; and with nickel ductile. With mercury it forms a fluid amalgam. Three oxides of palladium are known, viz.: Pd_2O , PdO , and PdO_2 . The last is also called palladic acid. Neither these nor the salts of the metal are specially important.

PALLADIUS. I. Surnamed **SOPHISTA** or **LABROSCOPHISTA**, a Greek medical writer, of whose life nothing is known except that he must have flourished between the 8d and 9th centuries of our era. He was the author of commentaries on the works of Hippocrates, "On Fractures," and "On Epidemics," and of a treatise "On Fevers," all of which are extant. II. **RUTILIUS TAURUS ÆMILIANUS**, a Roman writer on agriculture, who lived about the middle of the 4th century of our era. He wrote a treatise *De Re Rustica* in 14 books, in which he described in the form of a farmer's calendar the agricultural operations proper to each of the 12 months. The first book is introductory, and the last a poem in elegiac verse on the art of grafting. The work was very popular in the middle ages, and has been several times printed. There is an English translation of it by T. Owen (8vo., London, 1807). III. An early Christian father, born probably in Galatia about 367. At the age of 30 he embraced an ascetic life, and set out on foot to visit the solitaries of Upper Egypt, Libya, Syria, Palestine, Mesopotamia, and Italy. In 400 he was appointed bishop of Helenopolis in Bithynia, whence he was translated about 20 years afterward to the see of Aspona in Galatia. He wrote a collection of biographical notices and anecdotes of the monks whom he had seen in his travels, which is generally known as "the Lausiac history," from being addressed to Lausus, a chamberlain at the imperial court. It was edited by Meursius (Leyden, 1616). A Greek "Life of St. Chrysostom" and a treatise "On the Nations of India and the Bragmans (Brahmins)" have also been attributed to the bishop of Helenopolis, but their authorship is uncertain. Palladius was an adherent of Origen, and a bitter opponent of St. Jerome.

PALLAH. See **ANTELOPE**.

PALLAS. See **ATHENA**.

PALLAS, PETER SIMON, a German traveller and naturalist, born in Berlin, Sept. 23, 1741, died there, Sept. 8, 1811. He was educated at

the universities of Halle, Göttingen, and Leyden, at the latter of which he took his doctor's degree, and after a year's residence in England settled in 1768 at the Hague. He there pursued with avidity the study of zoology, and in 1766 published his first works of importance, *Elenchus Zoophyterum* (8vo.), and *Miscellanea Zoologica* (4to.), both treating of several classes of animals before erroneously included in the family of worms. The reputation acquired by these works procured him the offer from Catharine II. of a professorship of natural history in the imperial academy of sciences in St. Petersburg, where he established himself in 1767. Scarcely had he commenced his new duties when he was invited by the empress to join a scientific expedition into Siberia and other remote portions of the empire, for the purpose of observing the transit of Venus and of investigating the geography and natural history of the countries visited. The expedition set out in June, 1768, and during the next 6 years Pallas traversed a considerable part of southern Russia, the Caucasus, and central and southern Siberia, penetrating as far eastward as the frontiers of China. He returned to St. Petersburg in July, 1774, with shattered health, one of the few survivors of the expedition, and for many years was occupied with literary and scientific studies; but having in 1798 paid a visit to the southern part of the Crimea, he was so delighted with the climate, that he removed thither in 1795, and, with means liberally furnished to him by Catharine, built a handsome seat, in which he resided for 15 years. The climate proving less beneficial to his health than he had anticipated, he removed in 1810 to Berlin, where he died a few months after his arrival. His works are numerous, and according to Ouvier "have placed the name of their author in the first rank of naturalists." Among the most important are the *Spicilegium Zoologica* (4to., Berlin, 1767-'80), intended for the description and illustration of new or little known species of animals, and of which those parts devoted to the polar bear, the musk, and other quadrupeds encountered by him in Siberia, are of unusual interest; "Travels through different Provinces of the Russian Empire" (3 vols. 4to., St. Petersburg, 1771-'6), a work of much authority in geography and natural history, notwithstanding it was compiled during the author's travels, and without opportunities for consulting books of reference; *Novæ Species Quadrupedum e Glirium Ordine* (4to., St. Petersburg, 1777), containing descriptions of different species of the *rodentia* discovered by himself; "History of the Mongolian Nations," in German (2 vols. 4to., St. Petersburg, 1776-1801); "Observations on the Formation of Mountains" (4to., St. Petersburg, 1777); *Flora Rossica* (3 vols. fol., St. Petersburg, 1784-'8), a botanical work undertaken at the request of the empress, which was never completed; "Travels through the Southern Provinces of the Russian Empire in the Years

1793-'4" (2 vols. 4to., Leipsic; English translation, 2 vols. 4to., London, 1812); and *Zoographia Rosso-Asiatica* (8 vols. 4to., St. Petersburg, 1831), a work destined to embrace all the animals found in the Russian dominions, but of which the author only lived to complete the account of the vertebrates. In addition to these he contributed numerous papers on zoology, botany, geology, and kindred subjects to the "Memoirs" of the imperial academy of St. Petersburg, and other scientific publications; and the *Nordische, Neu nordische Beiträge*, &c., published by him in St. Petersburg between 1781 and 1796 (7 vols. 8vo.), contain many valuable essays on various branches of physical science. He also assisted in preparing at the command of the empress the vocabulary of all the languages of the empire, *Linguarum totius Orbis Vocabularia* (2 vols. 4to., St. Petersburg, 1786-'9; 2d ed., 4 vols., 1790-'91). Not the least important of his papers were those on the fossil remains discovered by him in Siberia. His services to modern geology were considerable, and according to Cuvier he is entitled to the credit of having discovered "the general law, which has since been completely verified, of the succession of the three primitive orders of rocks, the granite in the centre, the schistons on their sides, and the calcareous externally."

PALLAVICINO, FERRANTE, an Italian author, born in Parma in 1615, executed at Avignon, March 5, 1644. He became an Augustinian friar, and at first was reputed one of the most devout and learned members of his convent; but falling in love with a fair Venetian, he put off the frock and plunged into a career of licentiousness, supporting himself for some time by writing immoral books. He afterward went to Germany as chaplain to the duke of Amalfi, but without interrupting his debaucheries, and on his return put secretly to press a satirical work entitled "The Courier robbed of his Mail," to which the secretary of the Venetian republic had previously refused his imprimatur. The transaction being discovered, he was thrown into prison by the papal nuncio, but obtained his liberty again mainly by the assistance of one of his mistresses. When the war broke out between Pope Urban VIII. and the duke of Parma, he wrote in favor of the duke, using the most violent expressions against the pope and his nephews the Barberini, and among other pamphlets published *Il divorzio celeste*, in which he intimated that a divorce had taken place between Christ and the church. Afraid to remain in Italy, he resolved to visit France; but a fellow traveller betrayed him into the hands of the papal authorities at Avignon, and he was tried, condemned, and beheaded for apostasy and treason. He wrote a number of short pieces characterized by an extremely graceful style, but his celebrity is due quite as much to his personal history as his literary genius. His *Opere permesse*, edited by Brusoni with a life of the author (4 vols. 12mo.), ap-

peared at Venice in 1655, and his *Opere scelte* at Geneva in 1660.

PALLAVICINO, SFORZA, an Italian cardinal and author, born in Rome in 1607, died June 5, 1667. He was heir to a marquisate, but embraced the ecclesiastical state, and in 1637 became a Jesuit. He was made cardinal by Pope Alexander VII. His principal work is a "History of the Council of Trent," in Italian, written to counteract the work of Paul Sarpi on the same subject. The first edition (2 vols. fol., Rome, 1636-'7) is the best. It has been frequently reprinted and translated into Latin and French. Cardinal Pallavicino also wrote treatises "On Happiness" and "On Style in Written Composition;" a commentary on the *Summa* of Thomas Aquinas; a "Course of Theology;" "The Art of Christian Perfection," &c.

PALLIUM, or PALLA, an outer garment worn by both sexes among the Greeks, and occasionally among the Romans. It was a square or rectangular piece of woollen, linen, or cotton cloth, varying in color, texture, and ornament according to the taste of the wearer, and was worn in various ways, sometimes being merely wrapped around the body without regard to grace or appearance, sometimes fastened over the right shoulder with a brooch, and sometimes thrown over the left shoulder, brought across the back and under the right arm, and then thrown over the left shoulder again. The women's pallium was generally, though not always, of finer texture and more elaborate ornamentation than the men's; and the fops of ancient Athens used not unfrequently to array themselves in this effeminate costume. The pallium among the Greeks supplied the place of the toga among the Romans.—Pallium is also the name of an ecclesiastical ornament in the Roman Catholic church, worn by archbishops who are not merely titular. It was originally a sort of mantle or cape, but at present it consists only of a white woollen band about 2 inches wide which is worn around the shoulders and crossed in front. Crosses are worked upon it in black, and ornaments are attached to the ends. It is fastened in its place by golden pins. The pallium is made at Rome of the wool shorn from two lambs which the sisterhood of St. Agnes offer every year on their patronal feast while the *Agnus Dei* is sung at mass. It is sent by the pope to every newly appointed archbishop, and is considered the distinctive badge of the metropolitan dignity. The origin of the pallium is uncertain. Some Roman Catholic writers trace it to St. Linus, the second pope. According to others Constantine bestowed it upon Pope Sylvester, it being then a part of the imperial habit. At the council of Lateran in 1215 Pope Innocent III. decreed it to be a mark of the plenitude of the apostolic power, and that no archbishop should exercise his functions until he had received it.

PALM, a name applied to a number of endogenous plants, found in their greatest perfec-

tion within the tropics. They all agree in general characters, being monocotyledonous, with arborescent stems, rigid divided leaves, hexapetaloidous flowers, and in the embryo lying in a cartilaginous or fleshy albumen at a distance from the hilum. They are included in the natural order *palmaceæ*, which embraces the most interesting forms of the vegetable kingdom. The stem or trunk varies from the most humble condition, not unlike that of some globular cactus, to the most slender and graceful or large and well proportioned columns a hundred feet high; and in the leaves there exists as great a variety of forms, from those that are finely divided to those which are broad and fan-like, and of color from the liveliest green to a dull and ashy hue. The inflorescence shows itself below the leaves, while its shape is essentially modified by the mode in which it springs forth from the stem or trunk; and the fruit also has its variations both in color and in shape. The arborescent stem of the palms is usually a simple shaft, only now and then shrubby and branching; it is rough with the withered and persistent bases of the leaves, or else with the scars where they have at last fallen, and it is sometimes armed with stiff spines. The leaves are alternate, with a very hard epidermis and a distinct petiole, from the base of which a coarse network (*reticulum*) sometimes separates near the trunk. They are always borne in clusters at the summit, are folded together before expansion, and are of very large size, pinnate or flabelliform, but sometimes nearly split in two, their veins running in a parallel direction and the spaces between them plaited. Like the arums, their flowers are inserted upon a spadix enclosed in a sheath (spathe), which is proportionate in size to the leaves. Each flower is small, but the entire number contained in a single spathe is sometimes enormous; the perianth is 6-parted, arranged in 2 series, and persistent, the 3 outer segments smaller than the rest; the stamens, usually definite in number, are inserted into the base of the perianth; commonly they agree with the parts of the perianth, but sometimes they are only 8, and in a few genera where the flowers are polygamous the number is indefinite; the ovary has 1 to 8 cells or is deeply 8-lobed; the fruit berry-like (baccate) or drupaceous, and sometimes with very large, fibrous flesh; the albumen cartilaginous, and either ruminant or else furnished with a central or ventral cavity. The distinct species of the palms are supposed to exceed 1,000, and it is the opinion of Humboldt and Martius that there are yet a great many to discover in the equinoctial regions; though Schouw, a writer upon botanical geography, thinks we are already acquainted with the greater number, yet 65 new species of the East Indian palms were made known to science through the discoveries of Blume and Griffith alone. The actual limits of their growth seem to indicate in what unexplored regions of the globe they are to be

sought; and so tropical is their habitat that Bonpland found a new species in almost every 50 miles of his South American travels. The most northern limit in Europe is lat. 43° 44', where the *chamærops humilis* grows; and in the United States it is 84° 36', where the palmetto occurs. The ascertained species of the palms are arranged into about 70 genera, which have been divided by the best writers upon this subject into 5 principal tribes or families. Typical or prominent species of each one of these will be given as illustrations. 1. The *arecina* (Endlicher), of which we may notice the betel nut palm (*areca catechu*, Willd.). This is described by Roxburgh as being the most beautiful palm in India; its trunk is remarkably straight, 40 to 50 feet high, and generally 20 inches in circumference, equally thick in every part and smooth; its leaves are pinnate, the leaflets about 3½ feet long, and widest at the end; the nuts of the baccate fruit about the size of a hen's egg, of a reddish yellow color when mature, enclosed in a fibrous rind ¼ inch thick. It is this nut which forms the universal masticatory of the East Indies, its flavor being austere and astringent, which is overcome by a mixture of lime wrapped in the leaf of the betel pepper. The cabbage palm is another species (*A. oleracea*, Linn.); its trunk is very tall and even; its leaves are pinnate, the pinnae linear, very tapering-pointed, bifid; the spadix covered with white, deciduous, downy scales; flowers monœcious, petals imbricating in the fertile, but valvate in the barren; ovary 8-celled; spathes 2, membranous or fibrous. This species occurs abundantly in the mountainous districts of Jamaica and other West India islands, with a trunk not more than 6 or 7 inches in diameter, and of the height of 100 to 200 feet. The terminal bud of unexpanded leaves is very delicate and tender, forming the "cabbage," and considered a great delicacy when eaten raw or boiled; the kernel of the nut of the fruit is likewise white and sweet. Sometimes a large tree is felled for the sake of the cabbage; if it be left upon the ground and exposed to the air, the centre of the entire stem soon rots, leaving only the rind, which is very hard; and by this internal decay a natural cylinder or pipe is formed. The tree when growing is described as very graceful, the large pinnated leaves appearing only at the very apex and of a deep green color. 2. The *calameæ* (Lindley), represented in the rattan canes of commerce, have very slender stems and the general habit of the grasses, and were once considered as an intermediate link between the palms and the arborescent *gramineæ*. According to Blume, the several species are polygamous-dioecious or dioecious; spathes several, incomplete; flowers sessile in spikes, calyx 8-toothed or trifid, petals 8, united at base, stamens 6; anthers arrow-shaped, fixed by the back, accompanied by a rudiment of an ovary; the true ovary 8-celled, surrounded by a stamiferous cup usually sterile; style scarcely

any; stigmas 3, distinct or combined; berry protected by overlapping scales, 1-seeded, seed surrounded by a succulent flesh; leaves pinnated. The *calami* principally grow in the hotter parts of the East Indies, in the forests, climbing over trees and bushes by means of prickles, which are hooked backward, and, by the shortened and hardened terminal pinnae of the leaves, extending themselves to great lengths. The stem of the cable cane (*calamus rudentum*) grows 500 feet long, and one other kind mentioned by Rumphius grows to the length of 1,200 feet. Several species are supposed to furnish the rattans of commerce, which are used in the arts. The salxok (*C. zaiacca*) is cultivated in Java for the sake of its fruit, which is about the size of a walnut, containing 2 or 3 sweet kernels. The resin called dragon's blood of the best kind is derived from the outside of the ripe fruits of the *C. draco* and several other kindred species. The true sago palm (*sagus lavis*, Rumphius) is a native of the Indian archipelago. Sago is a kind of starch secreted by the tree for the use of its flowers and fruit, and is most abundant just before the evolution of the flower bud; the trunk is then cut down near the base, the pith extracted, sliced, and beaten in water until the starch separates from the fibres; these float upon the top and are skimmed off; the starch is repeatedly washed again, and finally put up in baskets made of the leaves of the tree; a single tree produces 500 to 600 pounds; this crude flour or powder passes through a process of roasting by which it is partially granulated, when it assumes the shape of small globules, and is in a condition for exportation. The leaves of the sago palm are pinnated, the flowers monœcious, the spadix branched without any common spathe, and the fruit hard, shining, its surface divided into numerous rhomboidal spaces. Another kind of sago is derived from the prickly sago palm (*S. Rumphii*, Willd.), a tree with pinnated foliage, the petioles and spathes guarded by strong prickles; this sort is chiefly used in India, and is rarely exported. 8. The *borassins* (Endl.) are represented in the wine palm (*borassus flabelliformis*), which, according to Sir William Jones, is justly considered the king of its order, and is a magnificent tree. It is described by Roxburgh as having dioecious, hexandrous flowers, the calyx and corolla in the barren consisting each of 3 distinct pieces, and in the fertile of from 8 to 12 pieces in a confused state; the ovary 8-celled, changing into a 3-seeded drupe. The plant grows all over India, both on the continent and in the islands, where it is esteemed of the greatest use on account of its vinous sap and the sugar that is extracted from it. Its trunk is from 25 to 40 feet high, and perceptibly thicker at the base than at the summit; the leaves are fan-shaped, 4 feet long, and borne upon stalks of the same length, which are spiny at their edges; each leaf is divided into 70 or 80 rays, the largest of which are placed at the cen-

tre; the fruit is of the size of an infant's head; 8-cornered, with the angles rounded and a little furrowed; it consists of a thick, fibrous, rather succulent, yellowish brown rind containing 3 seeds of the size of a goose's egg; the pulpy matter of the young seeds is cool and refreshing, but when ripe this pulp is changed into a hard bluish albumen, insipid and uneatable. This however is not the only palm which yields sugar and wine. The down palm of upper Egypt is the *hyphane coriacea* of Gärtner, and strongly contrasts with the usual character of the order by its dichotomous or forked stem; clumps of it appear near Thebes, and vast groves of it are found in the adjacent country. The fruit is about the size of an orange, angular, irregularly formed, of a reddish color, and has a spongy, tasteless, but nutritious rind, forming a common article of food among the wandering Arabs. The albumen of the seed is hard and semi-transparent, and is turned into beads and other small ornaments. The sea cocoa (*Lodoicea Sechellarum*, La Billardière) is a noble palm with a stem 80 feet high, and found only on the Seychelles, a small, rocky, and mountainous group of islands N. E. of Madagascar. Its fruit is very large, bilobed, and singularly shaped; for many years it was only occasionally met with floating at sea, and its rarity was so great that it was esteemed one of the most costly of regal gifts. Its habitat was finally discovered at these islands in 1743, after which it was described by Sonnerat; others assert that Alexis Marie de Rochon had noticed it as early as 1679. Great prices were at one time offered for a single nut, and one was valued as high as £400; specimens however are by no means rare in museums now. 4. The *coryphins* (Endl.) include the talipot tree of India (*corypha umbraculifera*, Linn.), which is a majestic palm with a stem rising to the height of 100 feet, terminated by a crown of immense leaves 18 feet long and 14 feet broad exclusive of the petiole; from the centre or bosom of these issues its terminal bud, which when the tree has arrived at maturity unfolds into a branching and outspread collection of lovely, fragrant, yellow blossoms, the odor of which extends to a great distance; each flower consists of a 3-toothed calyx, 3 petals, 6 stamens, and a 3-celled ovary. The fruits are round, 1-seeded berries, which are hard and of the size of cherries, but not good to eat. This inflorescence and fruiting occur but once in the lifetime of the plant, which after they have been perfected dies. The trunk is full of a mealy, pith-like substance, from which a sort of bread is made; the leaves are used for thatch, and as a writing material, for which an iron style is employed; and fans of an enormous size are also made of them. Another species is the tara or talliera (*C. talliera*, Roxb.), an elegant and stately tree inhabiting Bengal, its trunk 80 feet high and nearly of equal thickness throughout; its leaves are in 80 divisions, each 6 feet long by 4 inches broad, radiating

from the point of a leafstalk 5 to 10 feet long, and covered with strong spines on the edge; the spadix, which issues from the apex of the tree and from the centre of the leaves, forms an immense, diffuse, ovate panicle, 20 or more feet in height; the fruit is small, wrinkled, of a dark olive or yellowish green color. The date (*phœnix dactylifera*, Linn.) is probably the best known of the palms, and most likely the identical species to which the ancient name *palma* was applied; it was the palm tree of the Sacred Scriptures, and made emblematical of Judæa as we see it represented on coins. It occurs spontaneously in the desert and around Palmyra, which indeed is supposed to have been so named from its presence. It was introduced from Egypt and northern Africa into the south of Europe, being common also in Syria, Arabia, and the lower parts of Persia. The date palm is dioecious, its fertile or pistilliferous flowers being borne on a different tree from the stamiferous ones, rendering the crop entirely useless unless the tree has been either naturally or artificially impregnated; and it has always been the custom of the Arabs to hang clusters of stamiferous flowers on those trees which bore only pistilliferous ones. Hasselquist gives interesting accounts of this custom, which he tells us is preserved by the institution of a feast at the proper season of the year, called "the marriage of the palms;" and so well is this practice known, that the half savage tribes destroy the subsistence of their enemies by cutting down the male trees during their predatory excursions. Desfontaines and Kämpfer both corroborate this statement by their own experiences. The genus *phœnix* is distinguished by its sessile, dioecious, yellowish white flowers, which are borne on a branched spadix enclosed in a simple spathe; the calyx is urceolate, 3-toothed; the corolla has 3 petals (those of the fertile flowers are convolute); the stamens are 8 to 6, the filaments very short, anthers linear; in the fertile flowers the pistil has 3 ovaries distinct from each other, only one ripening; stigmas hooked; drupe 1-seeded; seed marked on one side by a longitudinal furrow, albumen reticulate, embryo in the back of the seed; the trunk is of moderate size and ringed or marked with the seams of the fallen leaves; the leaves are pinnate, with linear pinnae; fruit soft, of a reddish yellow color, and edible. The toddy tree (*P. sylvestris*, Roxb.) is common in the drier parts of India, with a tall, pretty thick trunk, and large yellowish or reddish fruit; it yields the *tarri* or palm wine, obtained by removing the lower leaves and sheaths, and cutting a notch into the centre of the tree near the top, from which the liquor issues. This, when collected, is either drunk fresh from the tree, or boiled down into sugar, or fermented for distillation, when it gives out a large portion of spirit. Baskets and mats are made of its leaves. 5. The *cocotinea* (Endl.) are represented in the cocoanut tree, the most interesting of the

genus *cocos*, the essential characters of which, according to Martius, are in its having upon the same spadix both male and female flowers, which are sessile; those of the male with a 3-leaved calyx, 3-petalled corolla, and 6 stamens; and those of the female 3 sepals and 3 petals rolled together, ovary 8-celled, stigmas 3 sessile; drupe fibrous, putamen with 8 pores at base, albumen homogeneous, hollow; embryos next one of the pores at the base; stem either lofty or middle-sized, slender, ringed or crowned with the base of the petioles; wood pale, fibrous; leaves pinnated, pinnae lanceolate or linear; flowers pale yellow; drupes brown, green, or orange color, rather dry. (See COCOANUT TREE.) The oil palm belongs to the genus *elæis* of Jacquin; it is the *maba* of the natives of Congo, and common all along the W. coast of Africa. The branches of inflorescence are unisexual; in the male flowers the sepals are 3, papery, dry; the petals are membranous lanceolate; the ovary 8-celled; the fruit an angular 1-seeded drupe with a fibrous, oily rind. The stem of the oil palm (*elæis Guineensis*, Linn.) is tall, of about 10 inches diameter, rough and bristling with the persistent bases of the petioles, which are spiny at their edges; the leaves are pinnate, 15 feet long, with 2 rows of ensiform pinnae each 18 inches long; the fruit is ovoid, of the size of a pigeon's egg, with its outer fleshy cover of a golden yellow color, the foramina of the putamen at the apex. The fruits (drupes) contain an emollient, demulcent, fixed oil in great abundance. (See PALM OIL.) This palm, according to Lindley, though a native of Guinea, is now common in tropical America. The vegetable ivory tree (*phytelephas*, Ruiz and Pavon) is commonly called the tagua plant, and in Peru it is termed the negro's head. The genus is referred to the natural order *pandaneæ* of Brown, but it seems to hold an affinity with the true palms in its pinnated fronds and erect stem; its flowers are arranged on a spadix enclosed in a universal spathe, and are of 2 sorts, the one containing stamens and pistils and the other only pistils; there are no visible sepals or petals; the style is divided into 5 or 6 segments; the fruit consists of quadrangular drupes, which are aggregated into a large, mucicated, coriaceous head; the seeds are about the size of a pigeon's egg, and of an oblong-ovate, triangular form; when young they contain a crystalline liquor without scent or taste and of refreshing quality, but in time this is converted into a milky fluid, and finally into a hard substance resembling ivory. There are two species, the large-seeded (*P. macrocarpa*), with a low stem, and the small-seeded (*P. microcarpa*), with little or no stem. In external appearance they look like something between a *cycas* and a true palm. These trees flourish in the valleys of the Peruvian Andes and on the borders of the river Magdalena. Their indurated seeds have been used by the natives for making buttons, heads to walking sticks, and

trinkets; but lately they have received the attention of other people in the manufacture of such articles as required the material of ivory. The structure of the albumen singularly resembles that of bone, traversed as it is by canals and tubes, but the same had been observed before in the seeds of the *sagus*, *cocos*, &c.—The palms are represented in North America by the palmetto (*sabal*, Adanson), which has perfect, sessile, bracted flowers, the calyx cup-shaped, 3-cleft, the corolla 8-petalled, stamens 6, hypogynous, filaments subulate, distinct, anthers cordate-ovate, horizontal; ovary 3-celled, styles united, 8-angled, stigma capitate, obtuse; fruit a 1-seeded drupe, embryo dorsal, albumen homogeneous, horny; stem simple or branched, erect or creeping; leaves fan-shaped, long-petioled, with the division 2-cleft at the apex, and often with long, thread-like filaments interposed; sheaths at base commonly composed of interlaced, dry fibres; spadix long, branching, with sheathing spathes at the joints; flowers small, white, rigid; drupe oblong or globose. The cabbage palmetto (*S. palmetto*, Roemer and Schultes) sometimes attains the height of 40 or 50 feet and a diameter of 12 or 15 inches. The leaves, 5 or 6 feet long, grow at the very summit of the tree; they are cordate in outline, pinnatifid, fan-shaped, recurved at the top, mostly shorter than the common concave petiole; the flowers are borne on naked panicles, and the drupe is bluish black and globose. This tree grows along the sea coast of South Carolina and Georgia, confined to the neighborhood of salt water, and preferring damp soils. Elliott speaks of its great value as a timber, not liable to attack by the ship worm (*limnoria terebrans*), incorruptible in salt water, and of importance in submarine construction; its leaves can also be used in the manufacture of hats, baskets, and mats, and for many purposes of domestic economy; and the unexpanded young leaves, or "cabbage," constitute one of the most delicious vegetables of the table. The saw palmetto (*S. serrulata*, R. and S.) has a creeping, branched stem, fan-shaped, bright green, circular leaves, and ovoid oblong drupe. It occurs on the southern islands of South Carolina, and in sandy soils southward to Florida. The dwarf palmetto (*S. Adansonii*, Pursh) has a creeping rootstalk, the stem buried in the soil; glaucous, fan-shaped, slightly pinnatifid leaves; spadix longer than the leaves, erect, smooth, and slender; drupe globose, bluish black; nut hemispherical. It is found growing in low grounds from North Carolina southward to Florida. The blue palmetto belongs to the Linnean genus *chamærops*, embracing species of low palms, with fan-like, long-petioled leaves, destitute of thread-like filaments; flowers polygamous, bracted, borne on a branching spadix, and enclosed in a 4-leaved spathe; calyx 3-cleft; corolla 3-petalled, yellowish; stamens 3 to 9, with the filaments connate at base; anthers oblong; ovaries 3, more or less united; stigmas acute, stigmated on the inner face;

drupes with 1 to 3 seeds, embryo dorsal, in horny, somewhat ruminated albumen. This species grows in shady woods in the lower districts from South Carolina to Florida; it was first noticed by Fraser, and called by him *C. hystrix*; its stem is short, proliferous, leaves circular in outline with numerous 3 to 4-toothed divisions on 3-angled, rough-edged petioles; sheaths at base persistent, composed of oblique fibres interwoven with numerous, erect, strong spines; it is remarkable for these thorns like porcupine quills, which grow from the root intermingled with the leaves, and which suggest the specific name.—The value of the palms to man can hardly be computed, as their various products enter so largely into the supply of his wants and even of his luxuries. The products of this tribe, says Humboldt, are wine, oil, wax, flour, sugar, salt; and Martius adds to the list thread, utensils, weapons, food, and habitations. Many of the useful purposes served by the cocoanut tree are noticed under that head, to which still others might be added. Other species are alike remarkable and of similar value, many yielding spirituous liquors, known as palm wine and the like; others affording different kinds of sago from the pith of the older stems. The gomutie palm (*gomutus saccharifer*, Rumphius), of the Indian archipelago, has hard timber suitable for buildings; its leafstalks afford strong black fibres, resembling horse-hair, for stitching together thatch or for making brooms; the midribs of the leaves are employed in making pins, and those fine arrows which the natives blow from long tubes; from the sap is made sugar or strong drink, and from the pith sago of good quality. A gum resin is obtained from *hyphæna Thebaica*, once extensively used as a diuretic and diaphoretic; the indispensable luxury of the Asiatics is the betel nut, the fruit of another species; the kernels of the fruit of the *attalea*, rubbed in water, form a useful emulsion for internal and external use; and the juice of the fruit of the *cocos schiophyllus* is employed in slight ophthalmic attacks. The fruit-bearing species, which need no more than a reference here, are eminently valuable, furnishing food to entire tribes of men; and those of other species, which have acrid properties, are yet capable of being made salutary by means that neutralize their peculiar dangerous principle. The palm oil used in the manufacture of soap and candles is a very considerable article of trade; and wax is abundantly secreted from the trunks and leaves of South American palms, of which the *carnauba* of Brazil throws it off in scales from its foliage. The resin called dragon's blood has been alluded to, and in the roots of the palmetto has been found tannin in considerable quantity.—The best idea of the palms can be gathered from Blume's *Rumphia* (folio, Amsterdam, 1835-'46); Royle's "Illustrations of the Botany of the Himalayas" &c. (fol., London, 1839); Martius's *Genera et Species Palmarum* (3 vols.

fol., Munich, 1828-'45); and from the various writings of Endlicher, Jussieu, Roxburgh, Schleiden, Griffith, and others. See also Elliott's "Sketches of the Botany of South Carolina and Georgia" (2 vols. 8vo., Charleston, 1821-'4); Chapman's "Flora of the Southern United States," &c.

PALM OIL, a fatty oil of the consistence of butter, of a rich orange color, sweetish taste, and odor like that of violets or orris root. It is the product of the fleshy integument or drupe of the stony fruit of the palm known as the *elais Guineensis* of W. Africa. The same oil is also obtained in Brazil, Cayenne, and the West Indies, and is probably yielded by other species of palm beside that named. To obtain it, the negroes remove the fibrous drupe, which having bruised they cover with boiling water. Upon this the oil rises and is skimmed from the surface. It retains the coloring matter of the drupe, which is removed in the subsequent treatment of the oil in the English factories, either by bleaching in shallow vats on the surface of hot water or by various chemical methods of treatment. Palm oil is imported into England from Africa to the amount of about 35,000 tons annually, about 20,000 tons coming from a single port of W. Africa. Each drupe affording only about $\frac{1}{4}$ of an ounce of oil, and each tree only 3 or 4 lbs. of it, an immense amount of labor must be expended in securing this product, and the forests of palm must be of great extent. A large part of the importation is consumed in the factories of Messrs. Price and co. (see **CANDLE**), in the manufacture of candles, and great quantities also go into the production of soap. Palm oil melts in a very thin fluid at temperatures varying from 75° to 95° F.; the older it is the greater the heat required to melt it. By age and exposure it becomes rancid and whitish. In ether it is perfectly soluble, slightly so in cold alcohol, and in boiling alcohol dissolves readily, but separates on cooling. It consists of margarine, oleine, and a solid fat resembling stearine and called palmitine, which constitutes about $\frac{1}{4}$ of its weight. This substance is further reduced to palmitic acid and oxide of glycerine. The change takes place in saponification; and as these ingredients also exist uncombined in palm oil, this is in better condition than any other oil for the process of soap making. In the manufacture of candles, the oil, having been melted by steam pipes introduced into the casks, and freed from impurities, is mixed with $\frac{1}{4}$ to $\frac{1}{2}$ of its weight of sulphuric acid, and is briskly agitated for about 2 hours in copper boilers heated by steam to about 350°. The glycerine and sulphuric acid by their mutual reaction are thus decomposed and escape partially in carbonic and sulphurous acids, and the remainder by subsequent washing. The impure acids are next distilled in copper stills heated by steam injected at a temperature of 600°. The dark residue in the retorts is made by pressure to yield further portions of oil at the

close of the distillation, and the black solid mass which remains is used for fuel. The distilled fat, when cooled to 50° or 54°, is broken into cakes 18 inches square and about 1 $\frac{1}{4}$ thick, which are distributed upon squares of coir or cocoanut matting, and these being piled upon each other are submitted to the action of a powerful hydraulic press at a temperature of 75°. The fat thus obtained may be run at once into candles for the European markets; but for tropical climates it is again submitted to pressure at a temperature of 120°. The soaps made with palm oil retain the natural agreeable odor of the oil.—In Africa palm oil is eaten to some extent by the natives as a sort of butter. In medicine it is recognized as an emollient, and employed sometimes in friction or embrocation, though possessing no specific virtue over other oleaginous substances.

PALM SUNDAY. See **HOLY WEEK**.

PALMA, the capital of the island of Majorca, in the Mediterranean; lat. 39° 34' N., long. 2° 45' E.; pop. 40,000. It is situated at the head of the bay of Palmas, and presents a picturesque appearance, as it is built on the slope of a hill with the large cathedral towering over the houses and fortifications. It is surrounded by a wall 86 feet thick, with 13 bastions and 8 gates. In some places the projecting eaves of the houses almost make a roof over the street. The cathedral is a handsome Gothic building. There are numerous churches, convents, and charitable institutions, and a public library of 40,000 volumes. Wool and silk are manufactured.

PALMA, JACOPO, the elder, an Italian painter, born in Serinalta, near Bergamo, about the close of the 15th century, died, according to Vasari, at the age of 48. He was educated in the school of Venice. His pictures are to be found in the principal private and public galleries of Europe, and are highly esteemed for tasteful composition and expression.—**JACOPO**, the younger, grand nephew of the preceding, born in Venice about 1544, died in 1628. His talents having attracted the notice of the duke of Urbino, he was sent by him to Rome, where, during a residence of 8 years, he studied the antique and the works of Michel Angelo, Raphael, and Caravaggio. Returning to Venice at the age of 24, he found the public favor and employment engrossed by Tintoretto and Paul Veronese; but he was able to rank next to them, and after their death he was without a rival in Venice. Examples of his best style are the "Plague of the Serpents," in the church of S. Bartolommeo, and the "Assumption of the Virgin" in the Ospitaletto. In the latter part of his life he painted so rapidly and carelessly that his pictures were little more than sketches. Lanzi calls him the last painter of the good and the first painter of the bad epoch of the Venetian school. He executed some etchings in a masterly style.

PALMAROLI, PIETRO, an Italian painter and picture restorer, born in the latter half of

the 18th century, died in Rome in 1828. He was the first to transfer frescoes from walls to canvas, and to his skill in the execution of this difficult process is due the preservation of Daniele da Volterra's famous "Descent from the Cross," in the church of Trinità de' Monti, now (Feb. 1861) in the gallery of the French academy. This was accomplished in 1811, and the interest which it excited among lovers of art caused similar means to be taken to save other works threatened with decay. As a restorer he brought to light innumerable beauties in obscured paintings. Prominent among these were Raphael's *Madonna di San Sisto* in the gallery at Dresden, and the fresco of the "Sibyls," by the same master, in the church of Santa Maria della Pace in Rome, the latter of which he was obliged to free from the restorations in oil made by the order of Pope Alexander VII.

PALMBLAD, VILHELM FREDRIK, a Swedish author, born at Liljested, Dec. 16, 1788, died Sept. 2, 1852. In 1806 he visited the university of Upsal, where he became a member of the society of the friends of belles-lettres, from which sprang the "Aurora Union." In 1810 he bought the academic printing office, and began the publication of the *Faxor*, in 1812 the *Poetisk Kalender*, and in 1813 the *Svensk Literaturtidende*, all of which periodicals had much influence in the development of Swedish literature. In 1830 he was made vice-president and subsequently president of the Swedish literary society, and in 1835 professor of Greek literature in the university of Upsal, and became editor of the biographical lexicon of distinguished Swedes. He wrote, beside other works, *Supplementa in Lexica Græca* (1822); a "Handbook of Geography" (1824); *Dagens Händelser* ("Events of the Day" 1839); and several novels, of which *Amala*, *Familjen Falkenavärd* (2 vols., Örebro, 1844-'5), and *Aurora Königsmark*, are the most deserving of mention. One of his most important works was the uncompleted "Handbook of Physical and Political Geography" (5 vols., Upsal, 1826-'37).

PALMEGLIANI, MARCO, an Italian painter, born in Forlì in the latter part of the 15th century, died subsequent to 1537. He was a disciple of Francesco Melozzo, and one of the ablest artists of his country at the period in which he lived. He had two styles, the first ascetic and formal, the second bold and pleasing with landscape or architectural backgrounds. He excelled in Madonnas. One of his best pictures, representing the dead Christ between Nicodemus and Joseph, is in the Palazzo Vicentini at Vicenza. Kugler says there are several clever pictures of his in the Berlin museum.

PALMELLA, DOM PEDRO DE SOUZA-HOLSTEIN, duke of, a Portuguese statesman, born in Turin in 1766, died in Lisbon, Oct. 12, 1850. He was first brought to notice at Bayonne in 1808, when, in the presence of the emperor Napoleon, he maintained the claims of Portugal to national independence. In 1814 he was sent by King John VI. as plenipotentiary

to the congress of Vienna, and afterward went to Brazil, where he held the post of minister of finance. Returning to Europe in 1818 on a diplomatic mission, he was president of the regency of Portugal on the outbreak of the revolution of 1820, tried to reconcile the royal and the liberal interests, held the premiership and the ministry of finance in the cabinet formed on the overthrow of the revolutionary constitution in 1823, and presided over a junta charged with devising a new one. On the first attempt of Dom Miguel to usurp power, he was arrested, April 30, 1824. Released by King John, he resumed *ad interim* the ministries of finance and the interior, till in 1825 he was appointed ambassador to England. On the death of John VI. in 1826, he adhered to Dom Pedro; and when in 1827 Dom Miguel was invested with the regency of Portugal, he at once resigned his post. The regent's usurpation of royalty, April 25, 1828, caused him to engage in active proceedings to restore Dona Maria, for which the usurper sentenced him to death for high treason. On the useless visit of Dona Maria to Europe in 1829, he was appointed president of the regency of Terceira, and in concert with Villafior upheld the young queen's cause with great energy and skill. When Dom Pedro assumed the regency in the name of his daughter in 1832, Palmella received the premiership with the department of foreign affairs, and a few months later went again to England as ambassador. Here he succeeded in raising money and enlisting troops on behalf of Dona Maria, returned to Oporto, where Dom Pedro was besieged, accompanied the naval expedition under Capt. Napier to Algarve, and entered Lisbon with Villafior, July 24, 1833. After the death of Dom Pedro, in Sept. 1834, the young queen Dona Maria made him her prime minister, which post he resigned a few months later in favor of Saldanha, retaining the ministry of foreign affairs. The insurrection of Sept. 9, 1836, again drove him into exile, but he was soon permitted to return. He played a subordinate part in the political intrigues that followed and ended in the triumph of Costa-Cabral; after the fall of that minister, he again received the department of finance, under the premiership of Saldanha, and held it for a little over a year.

PALMER, ERASTUS DOW, an American sculptor, born in Pompey, Onondaga co., N. Y., April 2, 1817. He was brought up to the trade of a carpenter and joiner, and followed that occupation in Utica until the age of 29. Shortly before this period, incited by the sight of a cameo portrait, and by a constructive talent which already exhibited itself in ingenious carvings on wood, he attempted with a piece of shell and a file to execute a similar head of his wife. Although entirely ignorant of the process, he wrought patiently at this work in the intervals of his daily toils, and exhibited it when completed to a gentleman of the neighborhood, of considerable taste and knowledge

of art, who encouraged him to persevere in this new occupation. For several years he occupied himself chiefly with cameo cutting, gaining gradually so much in facility of execution and reputation that he was invited to take up his residence in Albany. The injurious effect of this occupation upon his eyesight, as well as a conviction that so limited a sphere of labor did not afford sufficient scope for his talent, led him at about the age of 85 to attempt sculpture, to which he thenceforth devoted himself exclusively. His first work in marble, an ideal bust of the infant Ceres, modelled from one of his own children and idealized with a strict regard to nature as a basis, was exhibited at the New York academy of design, where it attracted much attention. It was followed by two bas-reliefs representing the morning and evening star, in which, as in the previous work, the careful finish acquired from working on cameos was a marked feature. A more important work than either of these was a statue of life size, representing an Indian girl contemplating a crucifix which she holds in her hand, and intended by the sculptor to typify the birth of Christianity in a savage mind. He has also executed in marble statues of the "Sleeping Peri," the "Little Peasant," and the "White Captive." The last, his most elaborate work, is a nude figure of a girl, bound to a tree, and having a mingled expression of despair, shame, and terror. All of these are conceived on ideal principles peculiar to the artist, and having little relation to the antique, which he never studied, and are distinguished by careful workmanship. His largest work in which the full figure is introduced is a design of the "Landing of the Pilgrims," embodying 15 statues, and intended for the capitol at Washington. Among his many works in bas-relief are "Faith," "Immutability," "The Spirit's Flight," "Sappho," and "Remorse," and of his ideal busts the principal are "Resignation," "Spring," and the "Infant Flora." He has also made portrait busts of Erastus Corning, Commodore Matthew C. Perry, Governor E. D. Morgan, and many others. Since his adoption of the profession of sculptor he has produced upward of 100 works in marble, and now pursues his calling at Albany. He is the only American sculptor of note who has never studied or practised his art abroad. His conceptions are his own, and his knowledge of his art and technical skill have been acquired wholly in New York.

PALMER, JOHN, an English dissenting clergyman and author, born in Southwark in 1729, died June 26, 1790. He was the son of an undertaker, and in 1759 became pastor of a dissenting congregation in London, with which he remained connected until 1780, when, having previously married a lady of fortune, he retired from the ministry, and devoted himself to literary pursuits. In the latter part of his life he abandoned the doctrines of Calvin for those of Socinus, and is said to have become an avowed opponent of all tests of faith. His

principal works are: "Observations in defence of the Liberty of Man as a Moral Agent," in reply to Dr. Priestley's "Illustrations of Philosophical Necessity" (8vo., London, 1779); an appendix to that production, and a "Letter to Priestley" on the same subject; a "Summary View of Christian Baptism," &c.

PALMER, JOHN, the first projector of mail coaches, born in Bath, England, about 1750, died in 1818. He was brought up as a brewer, but subsequently became the manager of a theatre in his native town. While travelling in this capacity from place to place for the purpose of securing performers for his company, he conceived the idea of conveying the mails by coaches with guards, on account of the greater security and expedition thereby attainable. After some opposition, he succeeded in making manifest the utility of his plan, and was appointed comptroller-general of the post office, a position which he lost in 1792, although he was subsequently reimbursed by parliament.

PALMERSTON, HENRY JOHN TEMPLE, 8d viscount, a British statesman, born at Broadlands, near Romsey, Hampshire, Oct. 20, 1784. He is descended from a younger branch of the Temples of Stowe, the founder of which was secretary to Sir Philip Sidney, and settled in Ireland in 1609. The celebrated Sir William Temple was his grandson, and uncle to the first Lord Palmerston, who was created a peer of Ireland, March 12, 1722, under the title of Baron Temple and Viscount Palmerston. The present viscount commenced his education at Harrow, went thence to the university of Edinburgh, where he studied mental philosophy under Dugald Stewart, and was finally graduated M.A. at St. John's college, Cambridge, in 1806. Deprived by the act of union of his seat as a hereditary legislator in the Irish parliament, Lord Palmerston, who succeeded to his title at the age of 18, had the alternative of taking his chance of election as an Irish representative peer in the house of lords, or of seeking admission into the house of commons. He chose the latter, and in 1806, when little more than 21 years of age, contested the representation of Cambridge university with Lord Henry Petty, the present marquis of Lansdowne. He was unsuccessful in this instance, but was almost immediately returned for the proprietary borough of Bletchingley, and in 1807 was made a junior lord of the admiralty in the tory cabinet of the duke of Portland. Between 1807 and 1811 he sat for the borough of Newport, Isle of Wight, and in the latter year he succeeded in securing the representation of Cambridge university, which from the outset had been an object of ambition with him, and which he retained for the next 20 years. His first important speech in parliament was delivered in opposition to a motion for the production of papers explanatory of the British expedition to Copenhagen in 1807, on which occasion he objected "to making public the working of diplomacy, because it is the tendency of disclosures

in that department to shut up future sources of information"—a principle in diplomacy on which he has since consistently acted. In 1809 he succeeded Lord Castlereagh as secretary at war in the Perceval cabinet, an office which he filled uninterruptedly in 5 different administrations during a period of 19 years. The accession of Canning to the foreign secretaryship in 1822 inaugurated a more liberal policy in the relations of England with the constitutional governments of the continent, and in that policy Lord Palmerston readily concurred, attaching himself thenceforth to the fortunes of the Canning party and its leader, and adopting at the same time the views of the latter on the subject of Catholic emancipation, parliamentary reform, and other domestic questions. He was nevertheless continued in office in the Wellington cabinet, which came into power on the death of Canning, but retired with the other members of his party when Mr. Huskisson was compelled by the hostility of the premier to resign. In 1828 he found himself for the first time in 21 years in opposition to the government, and in March of the succeeding year, and again in 1830 in a speech on the neutrality observed by the administration in the contest between Dom Miguel and the Portuguese liberals, he ably advocated the propriety of a more active and open sympathy with friendly nations engaged in a struggle for constitutional liberty. He now definitively severed himself from the tories, a step which brought upon him a large degree of ridicule and abuse from the journals of that party, and upon the accession of the whigs to power in Nov. 1830, was appointed by Earl Grey foreign secretary. He advocated Lord John Russell's reform bill, and thereby lost his seat for Cambridge university, but was in 1831 returned for Bletchingley. From 1832 to 1834 he represented South Hants, and since 1835 he has been regularly returned to parliament by the electors of Tiverton. He was prominent in effecting the recognition of the independence of Belgium, and in the formation of the quadruple alliance between England, France, Spain, and Portugal for upholding the cause of constitutional government in the two latter countries. During the brief administration of Sir Robert Peel, from Dec. 1834, to April, 1835, he remained out of office; but upon the formation of the Melbourne ministry he was restored to the foreign secretaryship, the functions of which he discharged until Sept. 1841. His reputation as a foreign minister was greatly extended during this second term of office, and over all parts of the continent his name "became synonymous with English diplomatic activity." His most noted achievement was the quadruple alliance with the northern powers to preserve the integrity of the Turkish empire. During the second Peel administration he remained in opposition, attacking the administration of foreign affairs by Lord Aberdeen with considerable severity, particularly the settlement of the boundary line between the state

of Maine and the province of New Brunswick, which he stigmatized as the "Ashburton capitulation." In 1846 he returned to the foreign office in the Russell cabinet, and in the various difficult questions of public policy which the revolutionary movements of 1848-'9 evolved exhibited his favorite policy of lending the moral weight of England's opinion to struggling nationalities, but at the same time refusing any practical assistance. Of the usurpation of extreme power by Louis Napoleon in Dec. 1851, he took a more friendly view than was at that time at all palatable to the English court. This disfavor was heightened by his subsequent refusal to permit his despatches to ministers at foreign courts to be submitted to the revision or inspection of Prince Albert, which led to his dismissal from office by Lord John Russell, at the instigation of the court. Public opinion ran high in his favor on account of what was deemed this manly and English-like assertion of independence, and he succeeded in a few months in overthrowing the ministry by which he had been discarded. For a time it was thought that with his customary pliability he would have taken the lead of the tory party, but a year later he entered the coalition ministry of Lord Aberdeen as home secretary, which position he held until Feb. 1855, when he was called upon to form the ministry by which the Russian war was brought to a close. In 1857 he despatched an army to suppress the mutiny in India, and at the same time set on foot the series of military operations in China which led to the important treaty ratified in 1860. His government was overthrown in Feb. 1858, for introducing the "conspiracy to murder bill" shortly after the attempt of Orsini on the life of the emperor. In June of the succeeding year he again formed a ministry which is still in power, and in which he occupies the position of first lord of the treasury. Although previously committed in favor of maintaining the integrity of the Austrian empire as a necessity in the European system, he advocated non-intervention in the Italian struggle of 1859, on the ground that in its relations with the Lombardo-Venetian provinces the imperial government had exceeded its legitimate authority. The overthrow of the Bourbon dynasty in Sicily and Naples in 1860 in like manner received his sympathy, but no direct assistance from the British government.—The long career of Lord Palmerston, extending through a period of 55 years, during more than 45 of which he has held office, is due not less to his industry and talent for statesmanship, than to his shrewdness and skill as a parliamentary leader, to his appreciation of the English character, and to his merits as a public speaker. His oratory possesses the rare quality of adaptability which renders him as effective on the hustings as on the floor of the house of commons, and is impregnated with a light and good-humored sarcasm, seldom exerted without effect upon unwary opponents. For clear and forcible statement, without need-

less verbiage, his speeches are unsurpassed by those of contemporary statesmen; and although he seldom rises to eloquence, he is never in any sense heavy. His appearance, notwithstanding his advanced age, is comparatively youthful, and his personal habits are those of great physical activity and much outdoor exercise. He is tall and erect in his carriage, walking usually with vigorous strides, and carrying his years in every respect most gallantly. His face is round, and his now scanty hair is a mixture of brown and gray. He devotes a considerable care to the embellishment of his person, and his clothes are in the extreme of the fashion of some 20 years since, fitting tight to his person. Unlike Canning, Disraeli, Russell, Gladstone, and others of his contemporaries, he has won his way to power without the aid of literary prestige. His views and opinions are to be found in detail only in parliamentary reports and blue books, and in his occasional addresses to the electors of Tiverton; but multitudes of dissertations on his foreign policy have been published both in England and on the continent, among which may be mentioned the publications and speeches of David Urquhart accusing him of being secretly and treacherously in the service of Russia, and of having betrayed the interests of England in the eastern question, and Count Ficquelmont's *Lord Palmerston, l'Angleterre et le continent* (1852). More elaborate works on the same subject are: "Opinions and Policy of the Right Hon. Viscount Palmerston as Minister, Diplomatist, and Statesman, with a Memoir, by G. H. Francis" (8vo., 1852), made up chiefly of extracts from his speeches; and "Thirty Years of Foreign Policy, a History of the Secretaryships of the Earl of Aberdeen and Lord Palmerston" (8vo., 1855). Lord Palmerston married, Dec. 16, 1839, the dowager countess Cowper, daughter of the first Viscount Melbourne; but the union being without issue, his title will expire with him.

PALMETTO. See **PALM.**

PALMYRA, an ancient city situated in a fruitful and well watered oasis in the Syrian desert, in lat. 34° 18' N., long. 38° 13' E., about 120 m. N. E. from Damascus. It was founded, or according to Josephus enlarged by Solomon, and its Hebrew name of Tadmor signifies, like its Greek and Latin one, the "city of palm trees." Situated nearly half-way between the Orontes and the Euphrates, it must early have been a commercial station of considerable importance to the carrying trade between the coast and the interior of Asia. Yet after the statement that Solomon "built Tadmor in the wilderness," it is not mentioned again in Scripture, nor is it spoken of by Xenophon nor in the accounts of the conquests of Alexander. In Roman history the first notice we have of it is by Appian, who states that Mark Antony marched to surprise and plunder it, but was disappointed by the inhabitants removing their goods beyond the Euphrates. Pliny refers to it as a city of merchants, an

emporium of the traffic between the Parthians and the Romans, and as having managed to preserve its independence although lying midway between these dangerous and often quarrelsome neighbors. In the reign of Hadrian it formed an alliance with Rome, and received many marks of favor from that emperor. It however did not attain to its highest dignity until the reign of Gallienus. Odenathus, a native of Palmyra, avenged the defeat and captivity of the emperor Valerian by driving back Sapor and the Persian army over the Euphrates. For this act he was honored by Gallienus with the title of Augustus, and recognized as his colleague in the empire. Odenathus, after a short but vigorous reign of 8 years, was assassinated by his nephew Maonius. But his wife, Zenobia, immediately took charge of the government, put to death the murderer of her husband, extended her sway over Mesopotamia and Syria, and assumed the title of queen of the East. During her reign of 5 years Palmyra reached its highest prosperity. As she refused to acknowledge the supremacy of Rome, and encroached upon Bithynia, Aurelian marched against her, defeated her forces in two pitched battles at Antioch and at Emesa, and finally beleaguered Palmyra itself (A. D. 273). After an unavailing defence, Zenobia fled to the Euphrates, but was captured by the Roman light horse. The emperor treated the conquered city with much consideration, although putting to death some of the advisers of the queen, one of whom was Longinus. He had just crossed the Hellespont on his return home, when news reached him of an insurrection, in which his garrison of 600 archers had been slaughtered. Turning back, he rapidly hastened to Palmyra, and massacred indiscriminately the inhabitants. From the effects of this blow Palmyra never recovered; it gradually sank into an obscure village, although it was garrisoned by Diocletian, and fortified by Justinian. It was taken by the Moslems under Abubekr, and again in 1400 by Tamerlane. After this it is not mentioned again in history, and for a long time even its site was unknown. Finally the accounts given by the Arabs of the magnificence of its ruins aroused so much curiosity, that an expedition under the auspices of the Levant company started from Aleppo in 1678 to explore, but were obliged to return without effecting their object. The enterprise was again undertaken in 1691, and this time was successful, and an account of the expedition was published in the "Transactions of the Royal Society." In 1751 it was visited by Wood and Dawkins, who published a description of their discoveries, illustrated with magnificent engravings.—The appearance of Palmyra across the desert is very striking, the countless columns of white marble, extending between one and two miles, strongly contrasting with the dead level of the sand. The principal ruin is the temple of the sun, which is remarkable for its grandeur. This stands in the centre of a court about 700 feet square,

and surrounded by a wall 70 feet high. On the W. side of this wall was the entrance, consisting of 8 gateways, of which the central door was 32 feet high and 16 wide. Upon its sides and lintels were monoliths, with garlands of fruits and flowers sculptured upon them, and which, though shattered, still remain. Around the inside of the wall were two rows of colonnades, of the columns constituting which 100 still exist. Around the shrine was a row of fluted Corinthian columns, although the other columns surrounding the temple are of the Ionic order. About 300 yards from the N. W. angle of the court of the temple, the great colonnade begins. There were at first 4 rows of columns, and when full they must have numbered 1,500, of which 150 are still standing, while numerous others are lying prostrate. Their height, including base and capital, is 57 feet. The tombs of Palmyra are very peculiar, and form perhaps the most interesting of its monuments. They are buildings like towers, 2, 3, or 4 stories high, each story constituting a chamber, which is divided so as to form separate compartments for the dead. In these fragments of mummy linen have been discovered, much the same as are found in Egypt. Tombs like these are only found in the Hauran, and they would seem to be of a date preceding the Roman conquest, most of them containing inscriptions in the Palmyrene character and language, a branch of the Syriac. The principal portion of the ruins, however, appear to indicate that the city was chiefly embellished from the reign of Hadrian to the conquest of Aurelian. The columns, with the exception of those of the temple of the sun, are in the Corinthian style, which was at that time the prevailing order. Palmyra is now inhabited by a small tribe of Bedouin Arabs, whose tents are pitched in the court of the temple. Among the travellers who have visited the ruins, Irby and Mangles, Cassas, Bankes, and Lord Lindsay may be named. For the history and antiquities, consult Wood, "Ruins of Palmyra" (London, 1798); Gibbon, "Decline and Fall of the Roman Empire," chap. xi.

PALO ALTO, a N. W. co. of Iowa, drained by the Des Moines river and its tributaries; area, about 600 sq. m.; pop. in 1859, 181. The productions in 1859 were 2,507 bushels of Indian corn and 2,965 of potatoes.

PALO ALTO ("tall timber"), the Spanish designation of a wood in S. Texas, about 8 m. N. E. from Matamoras, on the Rio Grande, famous for a battle fought near it on May 8, 1846, between about 6,000 Mexicans under Gen. Arista, and 2,800 soldiers of the U. S. army under Gen. Zachary Taylor. While Gen. Taylor was at Fort Brown, opposite Matamoras, he received intelligence that the Mexican general had crossed the Rio Grande above with a large force, and threatened Point Isabel, where the U. S. army had a depot of provisions. He therefore marched on May 1 to the relief of this place, which he reached before

Arista; and having put it in a fit condition for defence, he started upon his return on the 7th. On the 8th about noon he discovered the enemy in front of him, and in a position to intercept his return to Fort Brown. After a short halt for refreshment he formed his line in two wings. Col. Twiggs commanded the right, which comprised the 5th and 8d regiments of infantry, Ringgold's light artillery, 2 18-pounders, and 2 squadrons of dragoons. The left was under the command of Lieut. Col. Belknap, and consisted of 2 batteries of light artillery and the 8th infantry. At 2 P. M. the army advanced, and the Mexicans opened upon it a heavy fire of artillery, and charged the left with lances; but they were steadily forced back, the prairie grass was set on fire, and under cover of the smoke the Americans advanced. After an action of 5 hours, the Mexicans abandoned their position, and the Americans encamped for the night upon the field. The American loss was only 4 men killed, and 3 officers and 37 men wounded; the Mexicans had about 100 killed.

PALOMINO Y VELASCO, ACISLO ANTONIO, a Spanish painter and author, born in Buñalance in 1653, died in Madrid, Aug. 13, 1726. He studied theology and philosophy at the university of Cordova, but devoted himself to painting, receiving his first instructions in the art from Valdes Leal and Juan de Alfaro. In 1678 he repaired to Madrid, was appointed painter to the king, and soon ranked as one of the most eminent artists of Spain. Among his chief productions are the frescoes in the church of San Juan del Mercado in Valencia, and in Salamanca and Granada, illustrating scriptural allegory or church history and legends, and a fine series of altarpieces in the cathedral of Cordova. After the death of his wife in 1725 he took orders. He published a work on Spanish art under the title of *El museo pictorice* (Madrid, 1715-'24).

PALSY. See PARALYSIS.

PALUDAN-MÜLLER, FREDERIK, a Danish poet, born in Kjerterminde in the island of Fünen, Feb. 7, 1809. He early attracted attention by the publication of some romances and poems. His reputation, however, was founded upon the poem entitled "The Dancer" (1833), written in the manner of Lord Byron, which became at once exceedingly popular. His greatest work, *Adam Homo* (Copenhagen, 1841-'9), a didactic humorous poem, is regarded as one of the most remarkable productions of modern Danish literature. As an author he has been exceedingly prolific. Under the title of "Earlier Poems" (*Ungdomsarbejder*) he republished in 1847, in one volume, three of his first productions, "Cupid at Court," "The Dancer," and "Cupid and Psyche."—**CASPAR PETER**, a Danish historian, elder brother of the preceding, born in Kjerterminde, Jan. 25, 1805. In 1843 he became head of the cathedral school at Odense, and the same year member of the Copenhagen academy of sciences. He has

written several historical works and disquisitions, mostly relating to the northern nations.

PAMLICO RIVER, an estuary receiving the waters of Tar river and Tranter's creek, and opening into Pamlico sound, N. O. It is from 1 to 8 m. broad and 40 m. long, and navigable for all vessels which can enter the sound.

PAMLICO SOUND, a shallow body of water on the coast of North Carolina, separated from the Atlantic by long and narrow sandy islands, whose outermost point is Cape Hatteras; breadth from 10 to 80 m., length about 80 m. The principal entrance is by Ocracoke inlet on the S. W. It communicates with Albemarle and Currituck sounds on the N., and receives Pamlico and Neuse rivers on the W.

PAMPAS, a name applied to some of the vast plains of South America, particularly those stretching from Terra del Fuego N. through Patagonia and part of La Plata, over 27° of latitude, with an area of about 1,620,000 sq. m. They are traversed by numerous rivers, and the soil is in general poor, but in low places well covered with grass. There are patches here and there of algarobias and acacias. They are inhabited by ostriches and herds of guanacos; and the Spaniards introduced horned cattle and horses, which, running wild, have increased in immense numbers. Herds have been seen containing upward of 15,000.

PAMPELUNA (Sp. *Pamplona*; anc. *Pompeipolis*), a fortified city of Spain, capital of the province of Navarre, on the left bank of the river Arga, 197 m. N. N. E. from Madrid; pop. in 1848, 15,715. It is enclosed upon 8 sides by the Pyrénées; has several churches, one of which is dedicated to Ignatius Loyola, who was wounded here during a siege by the French in 1521, and conceived on his sick bed the idea of founding the order of Jesuits. Water is brought by an aqueduct nearly 12 m. long, carried through tunnels for about 8 m., and at one place over 97 arches, 35 feet in span and 65 feet high.—Pampeluna was founded by Pompey the Great, and captured by the Goths in 466, and by the Franks in 542. Charlemagne destroyed the fortifications in 778, and they were not rebuilt till the 11th century. Early in the 15th century Charles III. of Navarre made great alterations and improvements in the defences. The French took the place by stratagem in 1808, and held it till it was captured by the duke of Wellington after the battle of Vittoria in 1818.

PAMPHILUS, a Greek painter, born in Amphipolis, flourished between 890 and 350 B. C. Not above 4 or 5 of his pictures are specified by ancient authors, notwithstanding Quintilian states that he was one of the most renowned among the Greeks for composition. He was the master of Apelles, Melanthius, and other celebrated painters.

PAMPHILUS, an early Christian writer, born probably in Berytus, suffered martyrdom in Cæsarea, Feb. 16, 309. Descended from an influential and wealthy family, he studied in his

native city, and under Pierius at Alexandria. Subsequently he became a presbyter of Cæsarea in Palestine, at which place he passed most of his life. About the close of 307, during the persecution of the Christians by Diocletian, he was imprisoned by the governor of Palestine, because he refused to sacrifice to the gods, and remained in confinement until Feb. 309, when he was put to death. Pamphilus was the most intimate friend of Eusebius, who attended upon him during his imprisonment, and assumed the surname of Pamphili. With Eusebius also he probably wrote 5 books of "The Apology for Origen." At Cæsarea he formed a public library, consisting chiefly of ecclesiastical works, which became very celebrated in the Christian world. He also founded a theological school, designed chiefly to instruct the students in the exposition of the Scriptures. In conjunction with Eusebius he prepared an edition of the Septuagint, which became the one commonly used in the eastern church. Another work, entitled *Expositio Capitulum Actuum Apostolicorum*, has been ascribed to Pamphilus, but it is doubtful whether it was written by him or by Euthalius. The life of Pamphilus was written by Eusebius in 8 books, but these are all lost, with the exception of a few fragments, which are also doubtful; but events in his history have been collected from the other works of Eusebius, from Jerome, Photius, and others.

PAMPHYLIA (Gr. *παρ*, all, and *φυλον*, tribe—composed of many tribes or races), a district of ancient Asia Minor, comprised in the modern Turkish provinces of Anatolia and Adana. It is said to have been first called Mopsopia from Mopsus, a leader of one of those bands of Greeks who after the Trojan war were dispersed and settled at different places on the Asiatic coast. The later name was applied in reference to the mixed character of its inhabitants, among whom, in addition to the Greeks, were many aboriginal tribes from the interior. Pamphylia was upon the southern coast, and was bounded E. by Cilicia, N. by Pisidia, from which it was divided by Mt. Taurus, and W. by Lycia. It was a narrow strip about 90 m. in length, and formed an arch around a gulf of the Mediterranean called from it the Pamphylia gulf (now gulf of Adalia). The eastern extremity is flat and sandy, the western hilly with the ramifications of Mt. Taurus that run quite down to the coast. The western part of this district is at present a mass of incrustated vegetable matter, beneath which its various rivers, the ancient Catarrhactes, Cestrus, Eury-medon, and Melas, find their way to the sea. The waters of these subterranean streams rise to the surface of the sea in some places at the distance of $\frac{1}{2}$ m. from the shore.—Pamphylia was a province of ancient Persia, and in the war of Xerxes against the Greeks furnished 80 ships. When the Persian empire was destroyed by Alexander, Pamphylia became subject to Macedon and then to Syria. It subsequently

became a part of the kingdom of Pergamus, and finally a Roman province. The principal towns of Pamphylia were Olbia, Corycus, Aspendus, Perge, Syllium, Side, Cibyra, and Ptolemais; they were the chief depots at which the spoils of the coast pirates were sold. The language spoken was a mixture of Greek and native barbarous dialects.

PAN, in Grecian mythology, the god of flocks and shepherds. He was the son of Mercury by Callisto, Dryops, Eneis, or Penelope, or according to some authorities of Penelope by Ulysses or by all her suitors in common. He is represented with horns, a pug nose, and a goat's beard, feet, and tail, and was perfectly developed from his birth. When his mother first saw him she ran away in fright, but Mercury carried him to Olympus. He was called Pan (Gr. *pan*, all) from his being a favorite with all the gods. He was especially the companion of Bacchus, with whom he went to India. He delighted in noise and riot, and so frightful was his voice that, designing to help Phidippides against the Persians, he scared away the barbarians by a scream, whence originated the expression "panic fear." He also terrified the Titans in their war with the gods. He dwelt in grottoes, and wandered among the mountains and valleys, leading the dances of the nymphs, playing upon the syrinx or shepherd's flute, of which he was the inventor, and sometimes engaging in the chase. He was the patron of hunters, but was dreaded by travellers. He was the god not only of pastoral life but also of bee-keepers and fishermen, and according to Servius was considered as the god of nature generally, or a personification of the universe. The poet Pindar won his regard by his lyric songs. He loved the nymph Echo, by whom or by Pytho he became the father of Lynx, the nymph Pitys, who was metamorphosed into a fir tree, and Syrinx, after whom he named his flute. His worship, native in Arcadia, extended thence over other parts of Greece, and after the battle of Marathon was introduced into Athens. In Rome he was honored under the names of Inuus and Faunus. The fir tree was sacred to him, and sacrifices were offered to him consisting of cows, rams, lambs, milk, and honey. His attendants were the satyrs.

PANÆNUS, a Greek painter, who flourished in Athens about 448 B. C. He was a nephew of the sculptor Phidias, whom he assisted in making the statue of the Olympian Jupiter. A series of pictures by him at that place, illustrating mythological legends, is mentioned by Strabo, by which, according to Böttinger, we are to understand the paintings on the sides of the elevated base of the statue of Jupiter, described by Pausanias. His principal work was the battle of Marathon in the Pœcile at Athens, in which separate periods of the battle were represented, such as the first onset, the rout of the Persians, and the final contest at the ships, with portraits of Miltiades, Callimachus, Datia, Artaphernes, the mythical heroes The-

seus and Marathon, the goddess Minerva, and Hercules. This was one of the earliest pictures in which events were intelligently depicted, and the costumes and accessories were represented with some regard to truth and propriety. He occasionally engaged in the contest for prizes in painting at the Isthmian and Pythian games.

PANAMA, a city of New Granada, and the capital of the state of Panama, situated on the S. coast, on a bay of the same name, in lat. 8° 56' N., long. 79° 31' 2" W.; pop. about 10,000. The harbor is well protected, but so shallow that vessels of more than 80 tons cannot come within 2 m. of the shore. The usual anchorage for large vessels is 3 m. distant, near the island of Perico. The city has a fine cathedral, several convents, and a college, all of which are now in a decayed condition, and carries on some trade with Europe in pearls, shells, gold dust, &c. It owes its importance chiefly to the Panama railroad, of which it is the Pacific terminus. The old city of Panama, where the seat of the Spanish colonial government was established in 1518, was situated 6 m. N. E. of the present city. It was destroyed by the buccaneers in 1670, and is now a heap of ruins.

PANAMA, ISTHMUS OF, the narrowest point of the American continent, connecting North with South America. Formerly the name embraced the whole region between Tehuantepec and Darien; now it is confined to the strip of land lying between the E. frontier of Costa Rica and the district of Darien or Atrato, and embracing the different interoceanic routes which lie between Chiriqui and Golfo Dulce, Chagres and the bay of Panama, and the bay of Caledonia and the gulf of San Miguel. These limits are also those of the state of Panama, one of the 8 states composing the republic of New Granada. It is embraced between lat. 7° 20' and 9° 60' N., and long. 77° and 83° W. A line drawn from the head waters of the river Dorces or Dorces, falling into the Atlantic, to Punta Burica on the Pacific, separates the state from Costa Rica on the W., while on the S. E. it is bounded by the state of Cauca. In its widest part the distance from sea to sea is about 114 m.; in the narrowest, following the line of the railway from Navy bay to Panama, 47½ m. The area of the state is 29,756 sq. m.; pop. in 1851, 138,875; in 1861, estimated at 175,000, exclusive of 8,000 independent Indians occupying the district bordering on the state of Cauca. It is divided into 6 departments, viz.: Panama, Chiriqui, Fabrega, Herrera, Soto, and Colon.—The isthmus is traversed by a range of mountains, which joins the chain of Baudo near the gulf of San Miguel. Their highest peak is that of Picacho, 7,200 feet high, in the department of Chiriqui. The union of these two ranges and the prolongation of the second form the barrier between the Pacific and the valley of the Atrato, with an elevation of from 700 to 1,200 feet. Not fewer than 149 streams flow into the Atlantic from the dividing ridges of the isthmus, and 326 into the Pacific.

The largest is the river Tuira, falling into the gulf of San Miguel; it is 162 m. long, and is navigable for 102 m. Among other tributaries it receives the Cana, near the source of which are the celebrated gold mines of Cana. The river Chagres is navigable for 60 m. The coasts of Panama are fringed with beautiful islands, the most remarkable of which are those of Las Perlas in the Pacific, so named from their pearl fisheries, and Coiba or Quibo, area 180 sq. m., also in the Pacific. The best ports of the isthmus are, on the Atlantic, Bahia del Almirante or Chiriqui lagoon, San Blas, Caledonia, Colon, and Portobello; on the Pacific, the bay of San Miguel, Golfo in Golfo Dulce, and, in the archipelago of Montijo, the port of Damas in the island of Coiba.—In the E. districts of the state are various routes, more or less explored, which are supposed to offer facilities for an interoceanic canal. Oullen, Gisborne, Strain, Prevost, and Codazzi have examined at various times the line between Caledonia bay and the gulf of San Miguel, but have failed to obtain a satisfactory result. Various explorations of the country between the valley of the Atrato and the Pacific have also been made, with the same object. The best known are those conducted by Messrs. Trautwine, Porter, and Lane, and by Mr. Kennish, under the direction of Mr. F. M. Kelley of New York. A later exploration has been made by Lieuts. Craven and Michler, under the authority of the United States.—Some gold is now obtained in the rivers Mares, Balsas, Ocoelé, Belen, Indios, Santa Maria, Virigua, &c., and in the ravine of San Juan. The principal mines worked are those of San Antonio in Ocoelé, and that of Veraguas, but their joint product does not exceed \$150,000 annually. That great quantities of gold were anciently obtained is evident from the fact that the isthmus was called Castilla de Oro, and also from the abundance of the metal obtained from the *huacas* of Chiriqui. The districts of Santiago and Calobre abound in mines of salt, copper, iron, gypsum, lime, and coal. Coal mines are numerous in Boca del Toro and near Golfo Dulce, as are also those of iron in the mountains of San Cristobal. There are various thermal springs, and sea salt and tortoise shell are products of importance.—In the interior and on the flanks of the mountains the climate is relatively cool and salubrious. Much has been said of the mortality of Panama. Dr. Buell pronounces the miasmatic fever of the isthmus to be "a mild form of febrile disease, perfectly controllable by quinine;" and adds that its climate is comparatively healthy. The seasons are divided into the wet and the dry, the former lasting for 8 months of the year, from May to December inclusive; August, September, and October are the hottest months. At the beginning of January the temperature is very agreeable, and the nights are then almost cold.—Nearly all the vegetable products of the torrid zone may be raised on the isthmus in abundance; but the people devote them-

selves rather to commerce than agriculture, which is only pursued to the extent of supplying the transit with maize, rice, plantains, &c. The indigo plant grows spontaneously; and the experiments that have been made with coffee, tobacco, cacao, and other plants, have been very successful. Cotton is indigenous and perennial, and samples sent to Europe have been pronounced excellent. Cocoanut oil is produced abundantly, at little cost, and with small capital. Manufacturing industry is limited to the production of cloth and grass hammocks, coarse linen, grass (Panama) hats and knapsacks, pack saddles, matting, tiles, small boats, sails, soap, and a few other articles. Various dyeing materials, precious woods, wood for ship building, and valuable drugs are found, and Codazzi enumerates 55 varieties of fruit trees common to the isthmus.—The whole Atlantic coast of the isthmus, where Columbus found thousands of Indians, is now a solitary waste, the only inhabited localities being San Blas, Portobello, Manzanillo, Chagres, and Bocas del Toro. The Indians of the isthmus originally numbered not far from 300,000. They made a firm resistance to the invaders, especially at Darien and Veraguas; but they were rapidly extirpated, and even the establishments of their conquerors have almost entirely disappeared. Columbus in his last voyage, in 1502, discovered Chiriqui lagoon, called by his followers Bahia del Almirante, and established a colony at Belen, which however was soon abandoned. In 1508 Ojeda and Nicuesa visited the coasts of the Caribbean sea, and Nicuesa in 1510 founded Nombre de Dios and Portobello. In the same year Ojeda founded San Sebastian de Uraba, on the E. shore of the gulf of Darien, which however was soon abandoned. Enciso nevertheless built another town on the opposite shore of the gulf, which he called Santa Maria la Antigua, and which came ultimately to be the capital of the district. In 1513 Balboa discovered the Pacific. In 1514 reports of the immense riches of Castilla de Oro created great excitement in Spain, and led to the organization of an expedition of 1,500 men, under Pedro Arias Davila, for its exploration. The jealousy of Pedro Arias led to the execution of Balboa. The town of Nata was founded in 1517; in 1518, disgusted with Darien, Pedro Arias transferred the seat of government to Panama. In 1585 the conquest of Peru and the fame of the opulent empire of the incas attracted thither vast numbers of Spaniards, by way of the isthmus. It has been calculated that between 80,000 and 40,000 perished in the transit. In 1586 Drake sacked Portobello; the buccaneers under Morgan took it in 1665, and in 1670 reduced the castle of San Lorenzo at Chagres, and captured and burned Panama itself, for which reason its site was changed to the present one, 6 m. to the S. W. In 1680 they crossed the isthmus on the line of the river Ohuounaque, under Sharp, Ringrose, and Dampier, and took the city of

Santa Maria; this led to the closing of the mines of Cana in 1685, by royal decree. In 1698 William Paterson undertook the establishment of a Scotch colony at Puerto Escoques, on Caledonia bay. In 1719 the Catholic missionaries had succeeded in establishing a number of towns on the Atlantic coast and on the rivers flowing into the gulf of San Miguel, but they were all destroyed by the Indians. In 1790 a treaty of peace was made with the Indians of Darien, in compliance with which the Spaniards abandoned all their forts in that district, in which no white man has since settled.—The government of Colombia, and its successor that of New Granada, has always observed a liberal policy in respect to the isthmus of Panama, making all needful concessions for interoceanic communication across it, and now (1861) all its chief ports are free. The last charter granted for this purpose, and the only one which has taken effect, was conceded in 1847 to a French company, represented by one Mathieu Klein, for a railway; but failing to be carried out by him, it was transferred by Gen. Herran, minister of New Granada in the United States, to an American company composed of Messrs. Aspinwall, Chauncey, and Stephens, by whose efforts the existing railway was built. Since 1828 the idea has been mooted of opening a canal between the rivers Ohagres and Grande, falling into the Pacific near Panama, or the Trinidad and Caimito. The route was examined by two Flemish engineers under the orders of Philip II.; but finding insuperable difficulties, and for political reasons, the king ordered that no one should revive the subject, or make any propositions concerning it, under penalty of death. In 1826 Domingo Lopez, a native of New Granada, explored and traced a new line for a canal, 14 leagues in length, between Panama and Portobello. The first formal exploration, however, was that made in 1827 under the orders of Gen. Bolivar, by the engineers Lloyd and Falmark. Their labors, concluded in 1829, produced no result beyond that of satisfying the world that a railway, if not a canal, could readily be built between Ohagres and Panama. In 1848, in consequence of the representations of Humboldt and M. Alphonse Morel, the French government sent out Messrs. Garella and Courtines to make examinations. Garella reported in favor of a canal to pass under the dividing ridge of Ahogayagua by a tunnel 120 feet high and 17,890 feet long. In 1852 the government conceded to Dr. Cullen and others the privilege of building a canal between Caledonia and San Miguel. In 1855 it made a similar concession to Joseph Gooding and Ricardo Vanegas, for a canal in Choco, between the parallels of 4° and 8° N. The result of all the investigations made on the isthmus below Panama has been the general conviction that an interoceanic canal is feasible at several points, the sole question being that of cost. The Panama railway was located by Col. Hughes, and executed by Col. Totten as

chief engineer. The work was commenced in 1850, with a force of 5,000 men; and on Jan. 30, 1855, the first train passed from sea to sea. The estimated cost was \$5,000,000, but the high price of labor, due to the California excitement, and the necessity of obtaining all supplies from the United States, augmented the cost to \$7,500,000. The average annual income of the road since completion has been \$1,800,000, expenses \$850,000. The number of men employed in repairing and working the road is between 700 and 800. Up to 1858 the average number of passengers over the road was 81,000 annually; the average amount of treasure \$55,000,000, and of freight 66,000 tons. The finest work on the road is the iron bridge over the river Chagres, which is 650 feet long, and cost \$500,000. The only advantages which the government of New Granada has reserved from the railway are 3 per cent. of its net revenues, and \$10,000 annually as a compensation for the free transit of all foreign mails, against which however are to be calculated the numerous and heavy expenses incurred by the government to maintain order and give security to the traffic. The ports of the isthmus having been declared free for the benefit of the world-wide use of the transit, the revenue has been considerably diminished, and further curtailed by the refusal of the U. S. government to pay port dues levied by the laws of the country on all vessels entering its ports. By the treaty of 1846 between the United States and New Granada the two governments entered into a qualified alliance regarding the isthmus, in which the United States undertook "to guarantee positively and efficaciously to New Granada the perfect neutrality of the isthmus, with the view that the free transit from one to the other sea may not be embarrassed or interrupted, in any future time while the treaty exists; and in consequence, the United States also guarantee, in the same manner, the rights of sovereignty and property which New Granada has and possesses over the said territory."

PANATHENÆA, the most splendid of the Athenian festivals, celebrated in honor of Athena (Minerva) Polias, the protectress of the city. According to the common story, it was instituted by Erichthonius under the title of Athenæa; and this name it retained until the reign of Theseus, who united all the Attic tribes into one body, and this, becoming their common festival, was called Panathenæa. The festival was divided into two kinds, the lesser and the greater. The former was the one originally instituted, and took place every year; the latter, the origin of which has been ascribed to Pisistratus, occurred in the 8d year of each Olympiad. The difference between the two festivals was but slight, consisting in the greater solemnity of the latter, and in the peculiarity of a magnificent procession in which the peplus of Minerva was carried to her temple. The exercises of the festival were various.

There were 8 different kinds of combat, viz.: foot, horse, and chariot races; gymnastic exercises; and musical and poetic contests, at which rhapsodists recited the poems of Homer and other epic poets. The last, however, were introduced gradually, contests in singing and playing on the flute and cithara not having been known until the time of Pericles. The sacrifices were very costly, for every town in Attica and every colony of Athens was obliged to send a bull for the celebration. The festival probably lasted at first only one day, but the time was gradually extended, so that finally it seems to have continued for nearly 12 days. The chief attraction of the great Panathenæa was the procession, in which nearly all the inhabitants of Attica would appear to have taken part. The peplos of Minerva carried to her temple on this occasion was a crocus-colored garment in which were woven the victorious acts of the goddess. Phidias and his disciples represented this procession in the frieze of the Parthenon.

PANAY. See PHILIPPINE ISLANDS.

PANCOUQUE. I. ANDRÉ JOSEPH, a French author and publisher, born in Lille in 1700, died there, July 17, 1758. He was the author of several works, mostly compilations of no great value. On account of the free-thinking opinions expressed by him in a treatise entitled *Usage de la raison* (Lille, 1758), the clergy refused to grant him Christian burial. II. CHARLES JOSEPH, son of the preceding, born in Lille, Nov. 26, 1786, died in Paris, Dec. 19, 1798. He early became known by several treatises on mathematics, and at the age of 23 established himself as a bookseller in Paris, where he acquired an immense fortune, and where his house became a place of resort for the most distinguished men of letters in the capital. The *Mercur de France* was published by him. He also established the *Moniteur*, and was the editor of several important works, among which were the *Œuvres de Buffon*, a *Dictionnaire universel de jurisprudence* (27 vols. 4to.), and *Grand vocabulaire Français* (80 vols. 4to.). He was also the publisher of several translations, and formed the plan of the *Encyclopédie méthodique*. (See CYCLOPÆDIA, vol. vi. p. 182.) III. CHARLES LOUIS FLEURY, son of the preceding, born in Paris, Dec. 28, 1780, died at Fleury-sous-Meudon, July 11, 1844. Continuing the occupation of his father, he published several valuable works, translated the *Agricola* and the *Germania* of Tacitus, and wrote a "Description of the Isle of Staffa and its Basaltic Grotto" (1831). He left some translations in manuscript, including a French version of the "Darkness" of Lord Byron.

PANOREAS, a single, non-symmetrical glandular organ, situated in man transversely across the upper part of the abdomen, about on the level of the last dorsal vertebra; it is behind the peritoneum, at the posterior part of the epigastric region, on the spine and great vessels, between the 3 portions of the duodenum, be-

hind the stomach, and on the right of the spleen. It is of an irregular, elongated form, flattened from before backward, the left extremity very thin and prolonged to and sometimes beneath the spleen; the right extremity is rounded, resting against the 2d portion of the duodenum; the color is grayish white; the length is about 7 inches, width $1\frac{1}{2}$, and thickness 1 inch, and the weight 4 to 5 ounces; it is rather smaller in woman. The duct is in the interior, going from left to right, receiving in its course the excretory canal which comes from the larger end, or little pancreas as it is sometimes called; it opens into the duodenum, at the lower part of the 2d curve, by a special orifice, or one common to it and the bile duct; its arteries come principally from the splenic branch of the coeliac axis, and its nerves from the solar plexus. It closely resembles in structure the salivary glands, like the parotid; it is made up of clusters of secreting follicles forming the ends of the finely branching divisions of the duct; each cluster, with its vessels, nerves, and connecting areolar tissue, forms a lobule, and the several lobules are held together by the ducts, vessels, and areolar tissue; its development begins by a budding forth of cells from the intestinal canal. The secretion resembles saliva, being clear, colorless, somewhat viscid, with alkaline reaction, and slightly heavier than water; it contains from $18\frac{1}{2}$ parts of solid matters (in the ass) to nearly 100 in 1,000 (in the dog), of which the albuminous ferment is not perfectly coagulated by heat, though precipitated by alcohol, mineral acids, and metallic salts; it undergoes decomposition in a few hours; it possesses the power of converting starch into sugar, and with the intestinal secretion is concerned in the digestion of farinaceous food in the small intestines. (See CHYLE, and DIGESTION.) From the experiments of Bernard it seems established that an essential purpose of the pancreatic fluid is to reduce fatty matters to the state of an emulsion, and thereby promote their absorption by the lacteals; the oil, being reduced by a simple physical process to the minutest particles, each covered by a coating of albumen, is absorbed without decomposition, and passes unchanged into the tissues; this function is rendered the more probable by the relation between disease of the pancreas and the discharge of fatty matters from the intestines. The amount daily secreted by man, according to Bidder and Schmidt, is 5 to 7 ounces; the secretion is intermittent, and regulated by the digestive process, being most abundant at the commencement of digestion; the natural stimulus is the digestive process, and the consequent greater supply of blood through the sympathetic nervous connections. The organ is liable to hypertrophy, atrophy, softening, induration, inflammation extending from neighboring organs, simple and malignant tumors, fatty degeneration, and calculous growths. That the pancreas performs some essential function is evident from

its existence in all vertebrates, whether carnivorous or herbivorous, and from its presenting a constant relation to the duodenum, whatever be the proportions of the alimentary canal or the form of the organ; it is even found in a rudimentary condition in the invertebrates, and as low as the worms (*rotatoria*); also in the annelids proper, the gasteropod and cephalopod mollusks, and in many insects; it exists here as caecal appendages with thick walls, lined with ciliated epithelium, and opening into the beginning of the intestine. The pyloric caecal appendages of most osseous fishes have generally been regarded by anatomists as the analogue of a pancreas; they become more and more numerous and complex, from the simple ones in the turbot to the 60 in the salmon with a secreting surface of more than 82 feet; in the sturgeon they become united into a glandular organ. In some orders these caeca are absent, as in the sharks and rays, pike, and eel, in which the pancreas has the ordinary glandular form; some authors deny the pancreatic nature of these caeca, and maintain that they secrete a fluid only accessory to the true pancreatic secretion. In reptiles the pancreas is always present, often large, and in the higher orders more or less in contact with the spleen. In birds it is larger than in any other class, and it probably performs also the office of salivary glands, which are here wanting; it communicates with the intestinal canal by 2 or 3 openings; as a general rule the pancreatic secretion is poured in before the bile, though the ducts are so near together that no physiological conclusions can be drawn as to their separate actions; the greatest separation is probably in the ostrich, in which the bile duct opens close to the pylorus and the pancreatic duct 3 feet lower down; it is generally whitish red, large, elongated, and usually with 2 lobes. In mammals it differs from that of man chiefly in color and in its more or less division into lobes; in rodents, and especially in the rat, it is spread out in an arborescent manner; in the rabbit the duct enters the intestine from 9 to 18 inches from the pylorus, affording special facilities for studying its secretion. It is often called sweetbread in the calf, but this term more properly belongs to the thymus gland.

PANDA, a carnivorous plantigrade mammal, of the genus *ailurus* (F. Cuv.), which seems to connect the bears with the civets; by some authors it is placed with the civets. The teeth resemble those of the bears; the molars $\frac{1}{2}$ — $\frac{3}{4}$, or perhaps $\frac{1}{2}$ — $\frac{3}{4}$, a single unicuspidate false molar on each side above, the others tuberculate, and 2 tuberculate on each side below; the canines are nearly straight; the ears rounded and small; claws curved and semi-retractile; tail thick at the base and bushy; feet 5-toed, and the soles covered with thick fur. The only species described is the *A. fulgens* (F. Cuv.), inhabiting the snowy regions of Nepal; it is about the size of a large cat, with full and soft fur; the color above is chestnut brown, bright-

est on the shoulders, with throat, belly, and legs black; head whitish, with a reddish brown spot under the eyes; tail like a lady's boa, banded with red and yellow; it is rather an elegant animal. It is found in the neighborhood of rivers and mountain streams, living much on trees, and feeding on small birds and mammals; it is called *wah* from its cry.

PANDECTS. See CIVIL LAW.

PANDORA (Gr. *παν*, all, and *δωρον*, a gift), in Grecian legends, the first created woman. According to Hesiod, Jupiter, angry because Prometheus had stolen fire from heaven, ordered Vulcan to make a beautiful virgin, who was dressed by Minerva, adorned with fascinations by Venus and the Graces, and endowed with a deceitful mind by Mercury. She was brought to Epimetheus, who, disregarding the command of his brother not to accept from Jupiter any present whatever, received her while Prometheus was absent. When admitted among men, this "fascinating mischief" opened the casket in which all the miseries of mankind were kept, and every thing escaped except hope. Before this, according to the legend, "men had lived without disease or suffering; but now both earth and sea are full of mischiefs, while maladies of every description stalk abroad by day as well as by night, without any hope for man of relief to come." The more common version of the story makes Pandora to have brought the casket with her, and according to a later tradition the vessel contained the blessings of the gods, which she permitted to escape irrecoverably. In the Orphic poems, Pandora is ranked along with Heate and the Erinnyes as an infernal divinity.

PANEL. See JURY.

PANGAUM. See GOA, NEW.

PANGOLIN, or **SOALY ANT-EATER**, a burrowing edentate mammal of the old world, whose species constitute the genus *manis* (Linn.). These animals have the long pointed snout, toothless mouth, and extensile tongue of the ant-eaters, and the upper parts of the body and the tail armed with scales like the armadillos; the external ears are hardly perceptible; the scales are corneous and imbricated, permitting the body to be rolled up in a ball secure from the teeth of the largest carnivora; the limbs are short and robust, the hind ones the longest; the claws curved and formed for digging; the tail long, thick at the base. The skeleton has no clavicles, the stomach is simple, and the caecum is absent. They are found in the warm parts of Africa and Asia, living in holes which they dig in the ground or in the hollows of trees, and feeding upon insects, especially ants, which they capture on their long, round, and viscid tongue; the gait on the ground is awkward, as they walk on the outer side of the feet, with the claws turned in; they are harmless animals, though they display great strength and activity in tearing to pieces the hills of *termites* and other ants. The largest species is the short-tailed pangolin

(*M. pentadactyla*, Linn.), 3 or 4 feet long, with 5 toes, and the thick tail about as long as the head and trunk; it is found in India and Ceylon; the scales are deep brown in the adult animal, and hard enough to turn a musket ball. The *M. javanica* (Desm.), from Java and Borneo, has a habit of climbing trees. The long-tailed pangolin (*M. tetradactyla*, Linn.), from the coast of Guinea, is 4-toed, with a flatter tail nearly twice as long as the rest of the body; the scales are large, dark-colored, with yellow margin, arranged in 11 rows on the body, and armed with 8 points at the end; under parts covered with rough brown hairs; the whole length is between 2 and 3 feet. The *M. multicaudata* (Gray), also from the Guinea coast, has 19 or 21 rows of scales, small, yellowish gray, with 8 points behind. From their external covering and shape they resemble scaly lizards more than mammals; both surfaces of the tail are covered with scales. The flesh of the pangolins, which are probably the best protected of mammals against carnivora, is delicate and much prized by the natives of Africa. The *M. temminckii* (Smuts), a south African species, in total length about 2½ feet, is believed by the natives to have some influence upon cattle; hence, whenever one is taken, it is burned in some cattle pen, under the impression that the health and fertility of all animals afterward entering it will be increased; it is a comparatively rare animal.

PANIZZI, ANTONIO, librarian of the British museum, born in Brescelia, duchy of Modena, Sept. 16, 1797. He was educated at the university of Parma, which he left in 1818 and devoted himself to the practice of law. Taking part in the Piedmontese revolution of 1821, he was forced to flee, first to Lugano and afterward to Geneva and England. After a residence of a few months in London, he settled in Liverpool as a teacher of the Italian language. In 1828 he was called to the chair of Italian language and literature in the newly founded London university, which he held 2 years. In 1831 he was chosen assistant librarian of the British museum, and through his efforts and under his superintendence the library received a special parliamentary grant of £10,000 a year for its augmentation. The grand circular reading room in the centre quadrangle of the museum was suggested by him. Among the editorial labors of Panizzi are an edition of Boiardo's *Orlando innamorato* and the *Orlando furioso* of Ariosto (9 vols., London, 1830-'34); an edition of Boiardo's *Sonnetti e canzoni* (London, 1835); and an edition of Dante's *Inferno* (London, 1860).

PANJIM. See GOA, New.

PANNONIA, a province of the Roman empire, bounded N. and E. by the Danube, which separated it from Germany and Dacia, S. by the Save (Savus), separating it from Illyria, and W. by the Julian Alps and Mt. Cetius (now Kahlenberg), separating it from Italy and Noricum. It thus embraced the Trans-Danu-

bian circle of Hungary, the whole of Slavonia, and parts of the Military Frontierland, Croatia, Carniola, Carinthia, Styria, and Austria. It was traversed by various mountain ranges, the principal of which, in the S. and W., were called Alpes Pannonice. Beside the Danube and Save, the province was watered by the Dravus (Drave), Murus (Mur), Colapis (Kulpa), and Arrabo (Raab), all tributaries of the Danube. The inhabitants, mostly of Illyrian race, were divided into numerous tribes, and are described as brave and warlike, but cruel and treacherous. The Romans, by whom they were conquered under Augustus, and after a revolt and desperate struggle reconquered during the same reign, not only kept strong garrisons, but also built numerous towns and fortresses in Pannonia, among others Vindobona (now Vienna), Carnuntum (near Haimburg), Arrabona (Raab), Petavio (Pettau) on the Drave, Emona (Ljubljana), Segeste (Sissek) at the confluence of the Kulpa and Save, Taurunum (Belgrade), Sirmium (near Mitrovitz) on the Save, and Mursa (Essek). A dangerous mutiny of the Pannonian legions was quelled by Drusus shortly after the death of Augustus. The province was subsequently divided into Upper and Lower Pannonia, the former being the western, and partly separated from the latter by the Arrabo. In the reign of Galerius a part of Lower Pannonia was erected into a province under the name of Valeria. All the three provinces subsequently formed part of the Illyrian division of the empire. During the last period of the western empire Pannonia was successively occupied by the Huns and the Ostrogoths, and after its fall by the Longobards and other barbarians.—The name Pannonia is frequently used for Hungary by writers of that country.

PANOFKA, THODOR, a German archaeologist, born in Breslau, Feb. 25, 1801. He was educated at the gymnasium of his native city, and subsequently at Berlin, and early established his reputation among men of learning by a treatise entitled *De Rebus Samiorum* (Berlin, 1822). In 1822 he went to Rome, where a series of discourses on the tragedies of Sophocles, which he delivered before a small assembly of scholars, led to the establishment of the archaeological institute. In 1824 he travelled to Sicily, returned to Rome, and thence went to Paris, where, in 1827 he received from the duke de Blacas an invitation to arrange and catalogue the treasures of his museum. In 1828 he accompanied the duke to Naples, and superintended the excavations at Nola. In 1834 he returned to Germany, in 1836 became a member of the academy of sciences, and in 1844 was appointed extraordinary professor in the university of Berlin. His works are voluminous.

PANOLA. I. A N. W. co. of Miss., intersected by the Tallahatchie river; area, about 750 sq. m.; pop. in 1850, 11,444, of whom 6,420 were slaves. Its surface is generally level or rolling, and the soil fertile, especially

in the low lands. The productions in 1850 were 451,909 bushels of Indian corn, 74,583 of sweet potatoes, 15,889 lbs. of rice, and 8,918 bales of cotton. There were 5 grist mills, 20 churches, and 489 pupils attending public schools. Capital, Panola. II. An E. co. of Texas, bordering on Louisiana, intersected by the Sabine river, and drained by its branches; area, 750 sq. m.; pop. in 1858, 7,122 of whom 2,414 were slaves. It has a gently rolling surface covered with extensive forests of pine, oak, walnut, ash, and hickory, and a fertile soil. The productions in 1850 were 108,870 bushels of Indian corn, 88,405 of sweet potatoes, and 887 bales of cotton. Capital, Carthage.

PANSLAVISM. See SLAVI.

PANTHEISM (Gr. *pan*, all, and *theos*, God), that modification of religious belief, or philosophical speculation, which affirms that God is all; all being here taken as the unity, which underlies, and is expressed in, individual, multiple existences. The pantheist does not assert that every thing is God, for this were the grossest polytheism; nor even that God is every thing; nor yet that all is God, if all be understood in a collective sense, as the sum of individuals. The idea of unity (*una et unica substantia*) is essential to his system. It is monism, as claiming that there is but one substance, or spirit, in the universe, which alone has real and permanent being. It is acosmism, rather than atheism. It is virtual atheism whenever it denies that this one substance or spirit is a self-conscious intelligence. But atheism is rather the logical result of an exclusive materialism; while pantheism is the expression of an exclusive idealism. The word pantheism was first used in its present signification by Toland, in two of his works, 1705 and 1720 (the latter work was entitled *Pantheisticum, sive Formula Societatis Socraticæ*). Up to this time, pantheists were reckoned as atheists; Spinoza was charged, even by Bayle, with teaching "atheism." (See Böhmer, *De Pantheismi Nominis Origine*, &c., Halle, 1851.) Pantheism as a religious tendency is coeval with the earliest records of the race, outside of the Hebrew Scriptures. It appears, felt rather than thought, in the underlying unity of all things, in the Vedic writings; it takes the form of a fantastic imagination in the innumerable deities of the Brahminic worship, for all this host of gods was held to be but an emanation of the primeval and unchangeable *Māhān-Ātmā*, or spirit of the universe. In Buddhism, it made the final object of aspiration to be the absorption of man into the one substance; through *dhyāna* (contemplation) he is to attain to *nirvāna*, a blissful nonentity. Zeno and the Greek Eleatics taught that there is but one real existence in the universe, all else being a phenomenal and transient modification. The stoics reduced the world to a world-soul. Many of the Neo-Platonists held to a pantheistic scheme in the background of their eclecticism.

Even in the middle ages John Scotus Erigena, the enigma of his times, declares that "all which is truly said to be, is God alone;" and asks: "What could God be supposed to create, since he must be in all things, and can at the same time represent himself in no other being but himself?" Though employing some theistic phrases, he denies that any of the categories can be applied to deity. His doctrine was developed by Amalric of Bene and David of Dinante into a gross adoration of the flesh. Devout mystics, too, expressed the same tendency in the language of feeling rather than of thought. Master Eckart said that "God is nothing, and God is something;" and that "prior to the creation of the world God was not God, he was what he was." Suso, in his rapture, breaks out in the rhapsody, "that he is full of God; that there is nothing which is not God; that God and all things are one and the same." But it has been reserved for modern times to attempt the development of this system in a scientific method. Spinoza assumed its fundamental principle in his definition of substance, as the ultimate conception, and as necessarily infinite, coupled with his position that one substance could not be produced from another. Beside God, he says, no substance can be, or be conceived. (*Ethica*, prop. vi., viii., xiv.) This substance may have infinite modes; two of them we know, viz., thought and extension, i. e., the spiritual and the material. His method is mathematical, starting from and applying a definition. But his definition (of substance) is an assumption rather than an axiom; and his modes are not deductions from the definition, but superinduced upon it. The revolutionary capabilities of this scheme (which brought sin and free will under the category of necessity) were not fully felt until the later German philosophy resumed the discussion, in its attempt to construct a universal system on the basis of idealism. Kant's tenacious moral convictions, his belief in right as ultimate, and sin as real, and final causes as rational, made him a thorough-going theist. But Fichte, in his earlier speculations, deduced all being from the Ego, and identified deity with the moral order of the universe. Schelling, in his youthful theorizing, reacted from this subjective idealism. Absorbed in "the intellectual intuition" of the absolute, enamored with the calm method of Spinoza, and enthusiastic to restore nature to her rights, he identified deity with the essence of the universe; declaring that this essence, in its inmost idea, was the identity of the real and the ideal, the centre of indifference between the two poles of existence (the system of absolute identity). In his maturer scheme—the philosophy of revelation—he says that his earlier writings contained only the negative part of his speculations; and he supplemented them by the fundamental position, that the transition from the one to the many, from the absolute to the relative, could only be construed as an act of a self-conscious will. The subjec-

tive idealism of Fichte and the objective idealism of Schelling culminated in the absolute idealism of Hegel, who advocated the theory with a firmer grasp and a surer method. Being and thought, he asserts, are identical—identical in their nature and their laws. The absolute is not merely an abstract substance; it is spirit, it is subject, it is the idea. Its law of evolution is given in the principle of negation, which is real and logical both (identity of metaphysics and logic). God is this absolute spirit in this process. This spirit becomes objective to itself in nature, and returns to itself through the human spirit; God comes to self-consciousness in man. All reality is such only as it is an element in this process of deity. "The development of God in himself has the same logical necessity with the development of the universe; and the latter is so far divine as it is at every stage the development of the Divine Being." In this vast process of being, every thing is involved and included; there is a logical (real) necessity of self-development inherent in the divine idea. Sin is a negation, a perpetually vanishing factor. "The real is the rational; the rational is real." The incarnation is the generic union of divinity and humanity, found in the race as a whole. The Trinity is this universal process. Immortality is the prerogative of the absolute spirit. The absolute spirit knows itself in man; man knows the absolute, and in that absolute knows his inmost self; individual existences rise and fall, the eternal process alone abides for evermore.—Thus the historical development of pantheism shows that it was the product of religious imagination in the Orient; that it was abstract with the Greeks, and physical with the Roman stoics; was couched in the mysticism of mediæval times; became ontological in Spinoza; ethical and subjective in Fichte; objective, identifying the real and ideal, in Schelling; and attained its consummation in the dialectical processes of the Hegelian metaphysics. In some modern speculations, there have also been attempts to establish a materialistic pantheism; but a self-contradiction seems to be involved in the position that matter can be absolute or infinite.

PANTHEON (Gr. *παν*, all, and *θεος*, a god), literally, a temple dedicated to all the gods, or in which the worship of many gods was conducted. The most famous structure of this kind known to ancient or modern times is that in Rome, erected by M. Agrippa, the son-in-law of Augustus, 26 B. C., and consecrated in 608 by Boniface IV. as a Christian church, under the name of Sancta Maria ad Martyres, but which is still generally called the Pantheon. It stands in a piazza between the Corso and the Piazza Navona, near the centre of the ancient Campus Martius, and after the lapse of nearly 19 centuries is the best preserved of the monuments of ancient Rome. Pliny ranked it among the wonders of the ancient world. In shape it is a rotunda, 148 feet in diameter, surmounted by a dome, the grandest in existence,

and of which the summit is 148 feet above the pavement. In the centre of the dome is a circular opening 28 feet in diameter by which the building is lighted. (See DOME.) The most remarkable feature of the Pantheon, however, is its Corinthian portico, 110 feet in length by 44 in depth, composed of 16 granite columns, with marble capitals and bases, disposed in a triple row, each column being 46½ feet high and 5 feet in diameter. These columns support a pediment, the bronze roof of which was removed by the emperor Constantius II. and Pope Urban VIII. Forsyth pronounces this portico "more than faultless; it is positively the most sublime result that was ever produced by so little architecture" ("Remarks on Antiquities, Arts, &c., in Italy," London, 1818); and Ferguson, while alluding to the incongruity of attaching a portico to a rotunda, says the former is "perhaps the most satisfactory example of its class" ("Handbook of Architecture"), an opinion in which most authors who have described the building coincide. Other features of the Pantheon, such as the bronze doors, the niches and *adricula*, the marble cornice and the mosaic pavement of the interior, are in excellent preservation, and give an adequate idea of the original splendor of the edifice. An inscription on the frieze of the portico shows that it was erected by Agrippa in his 8d consulate, while another below records repairs by the emperors Septimius Severus and Caracalla. The solidity of its construction and its early conversion into a Christian church doubtless account for its excellent preservation at the present day. Some architects have imagined that it was originally intended and used as a bath; but passages in Pliny and other ancient authors, in which it is styled a *templum* and is mentioned as the receptacle of the images of many gods, sufficiently refute this notion. It contains the tombs of Raphael, Annibale Carracci, and other celebrated painters.

PANTHER (*felis pardus*, Linn.), a large African spotted cat, considered by Temminck and most modern naturalists as a variety of the leopard (*F. leopardus*, Linn., or *L. varius*, Gray), but regarded by Cuvier, Hamilton Smith, and others, as a true species. Skins of all the spotted cats vary so much, even the two sides of the same animal being unlike, that it is difficult to pronounce on the identity or non-identity of these two animals; travellers and furriers consider them the same, and naturalists have been too ready to follow their opinion. The description of the panther by Linnæus is factitious, and does not apply to any species of the genus; others of the older naturalists confound this animal with the jaguar (*F. onca*) of South America, sometimes called the American panther. Cuvier gives them as separate, this animal being the *pardalis* of the Greeks and the *panthera* of the Romans, and says if any leopard was by them confounded with it, it was the cheetah or hunting leopard (*F. jubata*). If not distinct

species, the panther and leopard are very marked varieties; the former is a more powerful animal, darker colored, with the crowded markings arranged with considerable regularity, and the tail longer in proportion; H. Smith describes one as $5\frac{1}{2}$ feet long without the tail, and $2\frac{1}{2}$ feet high at the shoulder; of a buff yellow color, approaching to ochrey on the back and sides, and with no white anywhere; with 7 vertical rows of imperfect dark rings on the sides, each formed by an assemblage of 5 or 6 simple spots, darkest within the rings, descending even to the knees; the tail spotted to the end, and a narrow black bar across the lower part of the throat; in the leopard the ranges are more numerous and the spots smaller. This is probably the animal so abundantly supplied to the public spectacles of ancient Rome, hundreds having been exhibited together. The panther is less common than the leopard, and confined chiefly, if not entirely, to Africa; it prefers thick coverts, and feeds on the smaller mammals like deer, antelopes, sheep, monkeys, and wild and domesticated fowls; it is an expert climber and very active; it is readily tamed; the female is gravid 9 weeks, and the young are born blind. The panther of South America is the jaguar, and of North America the cougar. (See LEOPARD.)

PANTIOPAÆUM. See KERTON.

PANTOGRAPH (Gr. *παν*, all, and *γραφειν*, to write), an instrument designed for copying maps and plans, either upon the same scale as the original, or one larger or smaller. It consists of 4 rods jointed together, forming a rhombic figure, which is set upon casters, so as to be moved freely over the paper upon which it is placed. One point in the plane of the instrument being made the centre of motion, a tracer is clamped at another point, which is to be guided by the hand over the lines that are to be copied. This is done by a pencil fixed upon one of the rods at any desired point for the scale required, so that as the tracer is moved in any direction the pencil shall make similar movements. An exact description of the instrument requires reference to figures. Another form of the instrument, invented by Prof. Wallace of Edinburgh, and called by him the eidograph (Gr. *ειδος*, image), is far superior to the old form of the pantograph in the precision and beauty of its application. In practice its action is so correct that the outline of a figure can be reduced by means of it to an almost microscopic minuteness with an accuracy which defies the most critical examination to detect an error. For a description of the instrument, see "Library of Useful Knowledge," "Practical Geometry," by Thomas Bradley, p. 59.—The pantograph was first described by Christopher Scheiner in a tract entitled *Pantographia, seu Ars Delineandi*, &c. (Rome, 1631). In the great exhibition of 1851 was an improved instrument of M. Gavard, by which tracings of maps were made upon a greatly reduced scale with extreme delicacy. A map of

France was thus produced, showing the departments within two inches square. If desired, figures can be copied by the pantograph in reverse.

PANTOMIME (Gr. *παν*, all, and *μιμεν*, to imitate), originally an actor who expressed by gestures, movements, and attitudes every variety of action and character; and hence in modern times a theatrical performance in which the action is represented by gesticulation, without the use of words. Pantomimic entertainments were common among the ancient Greeks and Romans, and by the latter were brought to great perfection about the time of Augustus, to whom or to the great artists who flourished in his reign their invention has sometimes been ascribed. The Roman pantomime, in his dress and manner of acting, very closely resembled the modern ballet dancer, regulating his movements by the accompaniment of musical instruments, especially of the flute, and making use of nearly every part of his body, except his face, which was covered by a mask, to express the action of the piece. So popular did the art become in the time of Augustus that his successor, Tiberius, was constrained to discountenance it by imperial decrees. Caligula and Nero, however, patronized the pantomimes, the latter frequently acting as one; and thenceforth to the latest period of the empire their performances enjoyed a high degree of favor. Mythological love stories, frequently of a lewd character, were favorite subjects in these entertainments, and occasionally a scene from a Greek drama, or the drama itself, was selected, each representation being based upon a text, called the *canticum*, which was sung by a chorus in the background. Women were at first prohibited from publicly performing as pantomimes, but subsequently they acted as such, not scrupling on occasions to appear naked; and the effect of such spectacles, in connection with the indecent subjects represented, is animadverted upon with severity by Juvenal in his satires. The early Christian writers also denounced pantomimic performances as the school of vice and licentiousness. In Sicily pantomimic dances were called *βαλλισμοι*, whence perhaps the modern words ball and ballet. The term pantomime is now commonly applied to a performance of a humorous character, not necessarily including dancing, in which feats of strength, agility, legerdemain, &c., are represented, and the action is conducted in dumb show by certain fantastic and conventional personages of Italian origin entitled Harlequin, Columbine, Pantaloon, &c., with the ordinary stage accessories. In the London theatres the Christmas pantomimes are a favorite annual amusement of a burlesque character, produced with splendid scenery and dresses, in which the action is carried on by dancing, gesticulation, and dialogue.

PAOLI, PASQUALE, a Corsican patriot, born at or near Morosaglia in 1726, died in London, Feb. 5, 1807. In his early youth he witnessed

the struggles of his countrymen, under his father Giacinto, against the Genoese and the French, followed his exiled parent to Naples in 1789, and was there educated. After completing his studies, he obtained an acquaintance with military tactics by serving as an officer in one of the Corsican regiments which the king of Naples had formed of refugees from that island. In 1755 his father sent him to Corsica, in company with his brother Clemente, who had become a Franciscan friar; and both eagerly engaged in the contest which their countrymen were now waging against the Genoese. The best Corsican generals had been carried away, and although scarcely 29 years old and entirely unknown to fame, Pasquale aspired to the first rank. His self-confidence and eloquence, aided by his brother's intrigues, won the day; he was unanimously chosen for the annual magistracy, and in a *consulta*, held July 16, was offered the supreme command of the troops. He modestly insisted upon sharing it with the old Mario Matra, with whom however he soon quarrelled; but Matra was killed in 1757, leaving him without a rival. He immediately summoned a *consulta*, procured for this body the confirmation of his rank as general for life, and, pursuing the war against the Genoese with renewed ardor, beat them back from the interior of the island, hemmed them in within a few seaports, defeated their army under Grimaldi, and organized a navy that seriously interfered with their trade. Having at last for a while freed his country of intestine and foreign war, he turned his attention to civil affairs, and improved the system of government and the administration of justice by the establishment of permanent courts, introducing uniformity of weights and measures, regulating the coinage, encouraging agriculture, manufactures, and commerce, and promoting the diffusion of knowledge by instituting a national printing press, and opening a university at Corte. He invited J. J. Rousseau to Corsica, requesting him to frame a constitution for the new republic, in conformity with the principles expounded in his *Contrat social*, but this project was not carried into execution. In 1765 he was visited by Boswell, whose journal, published in 1768, contributed much to his European reputation. The Genoese had not yet given up the hope of reconquering the island; in 1767 they entered into a contract with France to garrison the seaports for 4 years in acquittance of a debt to the republic; but their plans were baffled by Paoli, who not only repelled them, but captured the island of Capraja. Being disheartened, they sold their right to the French, and another and more terrible conflict commenced. At first Paoli succeeded in checking the advance of the invaders under Marbeuf and Chauvelin, and he even routed them at San Nicolao and at Borgo, forcing them to seek refuge within the walls of Bastia. But in 1769 an army of 22,000 men, under Count de Vaux, landed in the island, and soon completely subdued it. Paoli left his coun-

try in despair and sailed for Leghorn, whence he went to Holland, and finally to England. There he received a pension of £1,200, and lived for 30 years. The constituent assembly of France having allowed the Corsican exiles to return home, Paoli repaired to Paris, and, being introduced to the king by Lafayette, was promoted to the rank of lieutenant-general, receiving at the same time the military governorship of Corsica. When the island was formed into a department, he held the presidency of the administration, and was elected commander of the national guard. But the lawless and sanguinary proceedings of the convention soon estranged and shocked him; and, instigated by Great Britain, he organized a new rebellion, and was elected in June, 1793, generalissimo and president of a *consulta* which met at Corte. The French garrisons were driven from the island; English troops were landed there, and George III. was proclaimed "king of Corsica." Paoli, however, was disappointed in the treatment which he received from the English, and the viceroyalty which he had a right to expect was given to Sir Gilbert Elliot. When, two years later (Oct. 1796), the island was retaken by an expedition sent from Leghorn by order of Bonaparte, the exiled patriot removed to England, and passed the rest of his life in obscurity near London. By his will he bequeathed a large part of his fortune to establish schools in Corsica.—**CLEMENTE**, a Corsican patriot, elder brother of the preceding, born in Rostino in 1715, died there in 1793. He was a prominent leader in the Corsican war of independence against the Genoese and French. After the battle of Ponte Nuovo he retired to a convent near Vallombrosa, and there remained 20 years. When an old man he went back to Corsica, but died soon afterward.

PAOLO, FRA, or PAOLO SARPI. See **SARPI**.
PAOLO GIOVIO. See **GIOVIO**.

PÁPA, a town of S. W. Hungary, in the county of Veszprém, 26 m. N. W. from the town of that name, from which it is separated by the principal range of the Bakony; pop. 16,000, chiefly Magyars. It is situated on a small affluent of the river Marczal, and contains a castle belonging to the family of the Esterházy, several churches, synagogues, convents, and hospitals, and various important institutions of learning. The neighboring country produces wine. The principal manufactures of the town are cloth, paper, and stone ware.

PAPA VERONESE. See **CAGLIARI**.

PAPACY. See **POPE**.

PAPAL STATES, or STATES OF THE CHURCH (It. *Stati Pontifici*, or *Stati della Chiesa*), an independent state of central Italy, subject to the pope. Within the last year it has been reduced by the transfer of large portions of territory to Sardinia, but in the present unsettled condition of Italian affairs it will be convenient to treat of it as it existed in 1859. In this point of view it extends from lat. 41° 15' to 45° N., and from long. 10° 50' to 13° 55' E., and

is bounded N. by Venetia, E. by the Adriatic, S. and S. E. by Naples, S. W. by the Mediterranean, and W. and N. W. by Tuscany and Modena. Beside the compact territory thus described, it includes the delegation of Benevento, which is surrounded by the Neapolitan province of Principato Ulteriore, and the territory of Pontecorvo, enclosed by the Neapolitan province of Terra di Lavoro. Its greatest length is 280 m. from the mouth of the Po to Monte Circello, and its greatest breadth, from Ancona to Civita Vecchia, 140 m. For administrative purposes it is divided into a comarca including Rome and the Agro Romano, which is governed by a cardinal styled president; 6 legations, generally placed under a cardinal legate; and 18 delegations governed by inferior prelates. These, with their area and population in 1858, are as follows:

Division.	Area in sq. m.	Population.
Rome e Comarca.....	1,609	326,509
<i>Legations.</i>		
Bologna.....	1,430	375,631
Ferrara.....	823	244,524
Forlì.....	693	313,433
Ravenna.....	674	175,994
Urbino e Pesaro.....	1,353	257,751
Velletri.....	629	62,013
<i>Delegations.</i>		
Ancona.....	424	176,519
Macerata.....	561	243,104
Camerino.....	311	43,991
Fermo.....	317	110,331
Ascoli.....	440	91,916
Perugia.....	1,447	284,563
Spoletto.....	1,130	184,989
Rieti.....	513	73,663
Viterbo.....	1,068	123,334
Orvieto.....	301	29,047
Frosinone.....	730	154,550
Civita Vecchia.....	373	30,701
Benevento.....	58	28,176
Total.....	15,289	3,124,668

The legations of Bologna, Ferrara, Forlì, and Ravenna constitute the district known as the Romagna; Spoleto and Perugia are commonly called by the ancient name of Umbria; and the delegations of Ancona, Macerata, Fermo, and Ascoli are known as the Marches. The word march (It. *marca*) is an old term denoting a frontier territory governed generally by a marquis, and these 4 delegations formerly constituted the march of Ancona, the S. part of which (Fermo and Ascoli) was afterward erected into a separate march under the name of Fermo. The principal cities and towns are Rome, the capital, Bologna, Ancona, Ferrara, Ravenna, Sinigaglia, Faenza, Iesi, Perugia, Benevento, Pesaro, Macerata, Rimini, Fano, Forlì, and Fermo.—The coast line of the Papal States, comprising about 160 m. on the Mediterranean and 210 on the Adriatic, is in nearly all places low and often marshy. On the Mediterranean side the only coast town N. of the Tiber is Civita Vecchia, the port of Rome. About the mouth of the Tiber the land is not easily distinguishable from the sea, and the approach is rendered still more dangerous by the prevalence of thick fogs. S. of the Tiber the

seaboard presents the same dull flat aspect until a projecting headland, under which two large moles run out into the sea, marks the site of Porto d'Anzio, the ancient Antium, which in the time of Nero was a great seaport, but is now accessible only by small vessels. A plan has been adopted by the present pope for restoring the harbor and connecting it by railway with Rome. The vicinity is covered with interesting ruins. The vast malarious Pontine marshes begin here and extend to Monte Circello (anc. Promontorium Circæum), an isolated perpendicular mass of limestone. Terracina is 10 m. further S., on the Neapolitan frontier. Its harbor, once of considerable repute, became choked up, but was reconstructed by Pope Pius VI. On the Adriatic side the shore northward from the river Tronto, which marks the boundary with Naples, is low and sandy, but diversified with several small villages, as far as the promontories of Monte Ciriaco and Monte Comero, between which lies Ancona, the best Italian port on the Adriatic. The coast here rises somewhat, but there is no good anchorage from Ancona to Rimini, a distance of 50 m. About 12 m. further N. is the fishing town of Cesenatico, where a new harbor has lately been built; and beyond that is the mouth of the river Montone, on which, 5 m. from the sea, stands the decayed commercial city of Ravenna. The remainder of the coast is mostly a vast marsh, and about the delta of the Po, the S. branch of which forms the Venetian frontier, extensive dikes are built.—The most striking natural feature of the Papal States is the central ridge of the Apennines, which, after forming the boundary between Bologna and Tuscany, runs parallel with the coast, in a N. N. W. and S. S. E. direction, separating Umbria and the Marches from the Campagna di Roma. On both sides it sends off numerous ramifications. Those on the E. extend in parallel ridges toward the Adriatic, a distance of 30 or 40 m., enclosing fine valleys through which flow numerous short and rapid streams. Those on the W. reach in a few places as far as the sea, but the descent on this side is much less regular than on the other. The country around Perugia, near the point where the Apennines enter the Papal States from Tuscany, is a beautiful hilly region scarcely surpassed by any part of Italy. A broad and fertile valley, in which lie Foligno and Spoleto, and the fruitful valley of Terni separate it from the elevated table land of Rieti, at the foot of which lies the marshy and unhealthy Campagna. There are several isolated mountains on this side of the great range, of which the most remarkable are Monte Cimino, near Viterbo; Monte Santo Oreste (anc. Soracte), a mass of secondary limestone 2,250 feet high, rising from the midst of the Campagna; and the volcanic group of Albano, whose principal peak, Monte Cavo, has an elevation of 3,130 feet, also in the Campagna. The Apennines here have a maximum height of about 8,000 feet; they are bleak and

barren except on their lower slopes. The principal river of the Papal States is the Tiber, which rises in Tuscany among the Apennines, and, after passing Perugia and flowing through Rome, discharges itself into the Mediterranean by two mouths. It is navigable by steamers to Rome, a distance of about 24 m., and by small boats to the mouth of its principal affluent the Nera, 70 m. further. The Nera (Nar) has its source in the Apennines above Norcia; it is 70 m. long. The Fiora, Palidoro, and Amiseno, which fall into the Mediterranean, and the Po, Montone, Savio, Uso (believed by some to be the ancient Rubicon), Ohienti, Metauro (Metaurus), Tenna, and Tronto, which fall into the Adriatic, are the principal other rivers. The lake of Perugia, or Trasimeno (Thrasymenus), is celebrated for Hannibal's victory over the Romans, 217 B. C. Beside the lakes of Bolsena (Vulsinius), Bracciano (Sabatinus), Albano, and Nemi, the chief inland bodies of water are the lakes of Fogliana, Monaco, Crapolace, and Sarsa in the Pontine marshes, and the Valli di Omacchio, in the N. E. part near the delta of the Po, which is properly a vast swamp flooded by the sea.—The soil of the greater part of the Papal States is extremely fertile. Some of the higher mountain lands are nearly or quite barren, and others are adapted rather to pasturage than tillage; these latter are generally occupied by large flocks and herds. About one third of the entire surface is under cultivation. Some of the marshes have been rendered fruitful by draining, especially the Pontine marshes, which were partially reclaimed by Pius VI. No labor of drainage or cultivation, however, has succeeded in making them healthy, and their malarious influence extends even to the neighboring dry country. Fevers and agues are very prevalent here, as well as in the valley of the Po, and on the plain of Rimini. (See *MARITIME*.) The climate is mild in the S. districts, being tempered by sea breezes, and nothing but the deadly atmosphere prevents the Campagna from being one of the most beautiful regions in the world. Violent siroccos, however, are sometimes felt on the coast. The northern provinces, lying beyond the Apennines, and exposed to the influence of the snow-covered Alps, experience very cold winters, and the Apennines themselves are covered with snow from October to April. At Rome the mean temperature of the year is 60.4° F.; of the hottest month 76°, and of the coldest month 45°. The geological features of the Papal States are not particularly interesting. The whole N. E. portion consists of low flats, forming a continuation of the plains of Lombardy. S. of Rimini, as far as the Neapolitan territory, a belt of tertiary strata, composed principally of travertine, sandstones, and marls, extends along the Adriatic. W. of it lies a belt of upper secondary rocks, such as chalk and other calcareous formations, and W. of this again occurs a large deposit of Jura limestone. Separated from this

tract by a narrow tertiary zone is the volcanic region which stretches from Acquapendente in the N. to the S. of Velletri, and in some places extends as far W. as the Mediterranean. Basalt, tufa, and trachyte are the rocks chiefly found in this district. In the S. part of the Mediterranean coast the Jura limestone again appears, and sedimentary and cretaceous rocks, tertiary and travertine marls, or diluvial and alluvial deposits prevail in other places. No minerals have been found in any considerable quantities except iron and alum. Sulphur, saltpetre, rock salt, marbles, pozzuolana, bitumen, alabaster, gypsum, chalk, coal, fullers' earth, potters' clay, garnets, and rock crystals are the other most important mineral products. Sulphur springs and various kinds of mineral springs are abundant. The vegetable productions are wheat, maize, pulse, hemp, oats, barley, rye, rice, wine, oil, tobacco, sugar, indigo, and cotton, beside the orange, citron, pomegranate, and other fruits. The most valuable trees are the mulberry, which is cultivated with considerable care, the olive, oak, ash, elm, pine, and cork. Chestnuts are important articles of food. The forests are chiefly on the Apennines. Horned cattle, including buffaloes, are very numerous and particularly fine. Horses, sheep, pigs, and goats are abundant, and wild boars range in great numbers through the Pontine marshes. The lakes and rivers contain excellent fish, and there are valuable fisheries also in the Adriatic, but they are not prosecuted with industry.—The inhabitants, with the exception of about 10,000 Jews found chiefly at Rome and Ancona, are principally descendants of the ancient Romans, but they have few of the characteristics of the conquerors of the world. They are generally gay, cheerful, handsome, and well proportioned. Even the lowest classes display none of that rudeness and stupidity which are so often noticed in persons of the same rank elsewhere. They have quick understandings and a lively fancy. Keenly sensible of the beautiful or grand, they make pleasure the business of their lives, and delight in music and the other fine arts. Their vices are such as naturally spring from a warm temperament and a susceptibility to æsthetic enjoyments. They are irritable, passionate, jealous, and revengeful. An irresistible propensity to idleness seems to pervade all classes, and the beggars are notorious for their multitude and perseverance.—Agriculture is pursued with little skill and less industry. The lands are generally owned by great proprietors, and either farmed in large estates or leased in small parcels to the peasantry. The present pope has done much for the improvement of agriculture by insisting upon the duty of land owners to give employment to as many laborers as can profitably work their estates. Agricultural societies, with exhibitions and prizes, have been established in many cities, and that of Bologna publishes its transactions. The government also supports professorships of agriculture in the university of

Bologna and other places. The extent of arable land lying uncultivated was ascertained a few years ago to be about $\frac{1}{5}$ of the entire surface. Five sevenths of the inhabitants depend upon agriculture for their subsistence. The manufactures are not of much importance. Woollens, chiefly for domestic use, are made at various towns; silks of the finest quality at Rome and Bologna; there is an extensive production of leather at Ancona, Bologna, Pesaro, and Sinigaglia; smelting furnaces are in operation at Bracciano, Canino, and Conca; plate glass is made at Poggio Mirteto, rope in the N. provinces, and cotton to some extent at Rome. The refining of sulphur is an important branch of industry. Among the other manufactures are paper, alum, vitriol, artificial flowers, wax candles, soap, hats, catgut, licorice, refined sugar, and stone ware. The exports consist of most of the articles above named, with the addition of works of art, antiquities, grain, rice, wool, hemp, animals, timber, &c. The exports of hemp in 1856 amounted to \$8,203,851, and in 1857 to \$2,897,582, and those of raw silk in 1856 to \$1,298,198, and in 1857 to \$962,150. The principal imports are cotton, woollen, silk, and linen manufactures, wheat, buckwheat, maize, coffee, sugar, salted fish, and tobacco. The principal commercial port is Ancona on the Adriatic. The following table shows the values of imports and exports for the years 1856, 1857, and 1858, expressed in scudi, the scudo being equal to \$1.04.6:

Years.	Imports.	Exports.	Total.
1856.....	9,797,892	9,685,253	19,483,105
1857.....	12,027,483	11,635,835	24,352,737
1858.....	18,510,148	11,690,258	25,200,401

The movements of shipping for the same period were as follows:

Years.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1856.....	7,597	594,988	6,586	594,624
1857.....	8,863	683,900	8,487	694,290
1858.....	7,976	673,967	7,906	672,184

In 1859 the arrivals and departures were as follows:

Ports.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Adriatic.....	2,194	169,658	2,145	169,685
Mediterranean.....	2,205	358,169	2,315	357,785
Total.....	5,499	527,827	5,460	527,450

The imports in the same year were \$10,080,000 and the exports \$9,864,000. The shipping belonging to the Papal States on Jan. 1, 1860, amounted to 1,969 vessels with an aggregate burden of 87,125 tons. Of these, 1,671 (tonnage 82,467) were owned at ports on the Adriatic, and 298 (tonnage 4,658) at ports on the Mediterranean. The crews numbered 10,666 men. The trade of the Papal States is chiefly with Austria, Great Britain, France, Norway, and the various parts of Italy; there is very little with the United States.—The most im-

portant public works recently undertaken by the government are the enlarging and deepening of a number of ports, the establishment of telegraphic communication between Rome and its N. and S. frontiers, and the commencement of a system of railways. The line from Rome to Frascati, which is now open, is designed to connect at Ceprano with one extending to Naples. Another from Rome to Civita Vecchia is completed, and a third, from Rome to Bologna, is building. Lines from Civita Vecchia to the frontiers of Tuscany, from Bologna to Ferrara, from Bologna to the Tuscan boundary, and from Forli to Ravenna, have been projected. There are many excellent common roads, the most remarkable of which is the Via Flaminia Lauretana along the Adriatic, supported by immense works and crossing the Metauro by a long and splendid bridge. The magnificent viaducts between Albano and Genzano are also deserving of mention. The marshes of Ostia and the Ferrarese valleys have been thoroughly drained by steam power, and the great Appian way has been cleared.—The education of the lower classes in the Roman states is imperfect, though in each commune there is an elementary free school for boys under the superintendence of the parish priest, and in every city or town a free gymnasium or lyceum. Free communal schools for girls are conducted by religious sisterhoods, and the higher branches of female education are generally taught in convents. In Rome and the other principal cities the means of cheap or gratuitous education are abundant. The ratio of educated persons in Rome is estimated at 1 in 6 of the whole population. In England in 1851 it was 1 in 8 $\frac{1}{2}$, which is generally regarded as a satisfactory proportion. For higher studies there are 7 universities, viz.: at Rome, Ferrara, Bologna, Urbino, Macerata, Camerino, and Perugia, having all the usual faculties. Admission to these institutions is free, the only charge made to students being on taking out degrees; the average charge for each degree is \$20, and this is generally remitted in whole or in part when the student is too poor to pay it. Degrees are also given gratuitously as rewards of merit. The number of students attending the universities and higher seminaries is about 29,000.—The established religion is the Roman Catholic, and other creeds are barely tolerated. According to the last census the Jews numbered 2,237, and other non-Catholics 263. The clergy are very numerous. The highest place after the papacy is held by the cardinals, who rank as princes. Their established number is 70, but there are always several vacancies. They do not all reside in the Papal States. (See CARDINAL.) There are 9 archbishops, 52 bishops, 16,905 secular clergy, and 21,415 men belonging to various religious orders. The number of monasteries is about 1,800, of nunneries 600, and of nuns 8,000. Many of the secular priests are extremely poor, but the convents frequently possess valuable property.—The

government of the Papal States is an absolute elective monarchy. The pope for the time being is the supreme head of the state. He is chosen by the college of cardinals, a vote of $\frac{2}{3}$ being required to elect; but until the time of Nicholas II. (1059) he was elected by the whole clergy and people. He is assisted by a council of ministers, composed of the heads of the departments of state, the interior, commerce, finance, and war, the director-general of police, and the advocate-general of fiscal matters. These ministers may be either ecclesiastics or laymen. At the present time the secretary of state and president of the council is Cardinal Antonelli, and all the others except one (Baron Baldini) have the title of "prelate" (*Monsignore*), which gives them clerical rank so long as they retain office, though they may not be in orders. Measures proposed in the council of ministers are afterward referred to the council of state, which is composed of a cardinal president, 3 prelates, and 9 laymen. In many cases relating to administration their jurisdiction is absolute, but in matters of legislation their vote requires the sanction of the pope. Financial concerns are regulated by a third council called the *consulta* of state for the finances, and consisting of a cardinal president, a prelate for vice-president, 2 prelates and 8 laymen appointed by the pope, and 23 laymen selected by the pope from a list of candidates chosen by the provincial councils. Each province is governed by a president, who is assisted by a board of 4 lay councillors, having a decisive vote in matters of local finance and taxes, and by a provincial chamber of representatives. The presidents are appointed at Rome, and may be either prelates or laymen. The provincial councillors are nominated by the municipal or communal councils, and these are chosen by the electoral body, which consists of the most highly taxed inhabitants of the commune, with the addition of those who have acquired the higher degrees at the universities. The communal council appoints the local magistrates, all the other officers and servants of the commune, the communal attorney, receiver, and schoolmaster, the surgeon and apothecary, who is obliged to attend the poor gratis, the local police, &c. The administration of justice is conducted according to the civil and canon law, together with the *Motu Proprio* of Gregory XVI., 1831. The judges are appointed by the pope and removable at pleasure. The principal tribunal is the *corte della segnatura* at Rome, which resembles the French court of cassation. There are courts of appeal in all the chief cities, civil and criminal courts in every province, tribunals of commerce at Ancona and other places, magistrates' courts in the communes, and bishops' courts for trials between ecclesiastics. The proceedings are public in all tribunals except the *consulta* instituted for the examination of political offences. In this the testimony is shown to the accused in writing, and he is not confronted

with the witnesses. The most serious defects of the judicial system are vexatious delays and the frequency of arrest on suspicion. Capital punishment is extremely rare. The usual penalties are imprisonment with or without hard labor, and for many political offences banishment. In 1855 the whole number of laymen holding office under government was 6,854, with salaries amounting to 1,499,729 scudi; and the number of ecclesiastics, including 179 chaplains of prisons, was 292, with salaries amounting to 127,857 scudi. The military force, June 30, 1860, amounted to 24,279 men, viz.: 20,265 infantry, 1,330 cavalry, 2,510 artillery, engineers, invalids, &c., and 174 attached to the ministry, staff, &c. This includes the Irish brigade (950 infantry and a battery of artillery), which has since been disbanded, but does not include 3,400 men belonging to the corps of the duke of Modena, who were received into the papal service in Aug. 1860. The French army of occupation maintained in the Papal States for the protection of the holy see amounted in 1860 to about 12,000 men of all arms. The navy comprises only 5 vessels, with an aggregate armament of 25 guns. The budget for 1860 represents the revenue and expenditure as follows:

Branches.	Revenue, scudi.	Expenditure, scudi.
Direct taxes and domains	2,673,514	556,700
Customs and excise	7,690,930	2,339,591
Stamps and registration	1,045,104	116,453
Post office	574,956	263,632
Lotteries	1,116,957	737,853
Mint	58,513	44,692
Public debt		4,977,476
Licenses	321,596	
Ministry of the interior	44,650	1,508,349
" of commerce	139,444	741,366
" of war	12,940	2,345,455
Census		86,541
Miscellaneous	\$10	1,344,575
Total	14,453,325	15,019,346

The sum of 100,000 scudi is kept back every year as a sinking fund, so that the total deficit for 1860 is 666,021 scudi. The revenue up to 1830 had been for some years considerably more than the expenditure. The revolution of 1831 produced a large annual deficit, which was gradually reduced to 350,000 scudi in 1847. The revolution of the next two years raised the deficiency to 6,600,000 scudi, and it was again reduced until it amounted to 1,101,495 in 1855, 777,660 in 1856, and 552,302 in 1857. There was a surplus of 42,066 in 1858 and 83,507 in 1859. The public debt amounted to 65,006,193 scudi in 1855, 64,233,749 in 1857, 66,471,274 in 1858, and about 77,000,000 in 1859. Of the debt in 1858, 28,875,000 scudi consisted of foreign loans, 34,201,240 of the permanent interior debt at 5 per cent., and the remainder of floating liabilities. The average rate of taxation, reckoning all sources of revenue, is about \$4.73 to each inhabitant; in the United States it is less than \$3, in France nearly \$10, and in Great Britain \$11.70.—The origin of the temporal sovereignty of the pope is involved in

considerable obscurity, but it seems probable that it grew up imperceptibly out of his spiritual authority, and was confirmed by, if not based upon, the free choice of his subjects. About the time of Constantine some landed possessions seem to have been attached to the see of Rome which partook of the nature of principalities. By the time of Leo the Iconoclast and Gregory II. (726) the power of the popes, who occupied a dangerous station among the barbarians of the West, while the emperors, to whom they still professed subjection, held their court at Constantinople, had acquired no slight importance. "Their popular election," says Gibbon, "endeared them to the Romans; the public and private indigence was relieved by their ample revenue; and the weakness or neglect of the emperors compelled them to consult, both in peace and war, the temporal safety of the city." The invasion of the Lombards, who, after capturing Ravenna, the seat of the exarch or imperial viceroy, finally laid siege to Rome itself in 741, and the neglect of the Byzantine emperors to take any measures for the protection of their Italian subjects, compelled the pope to look elsewhere for help. Gregory III. accordingly sent an embassy to Charles Martel, offering him in the name of the Roman senate and people the dignity of patrician, and imploring his assistance. Charles was preparing to cross the Alps with an army when he was cut off by death, and the pope died in the same year; but his successor Zachary succeeded in keeping back the invaders, reestablishing the exarch, and obtaining the restoration of the captured cities. On his death the Lombards made a fresh invasion, the exarchate was again overthrown, Rome was again attacked, and Pope Stephen III. called in the assistance of Pepin. The Frankish ruler marched into Italy, defeated the Lombard king Astolphus, and obliged him to give up to the pope the greater part of the exarchate of Ravenna, comprising the 5 cities of Rimini, Pesaro, Fano, Sinigaglia, and Ancona, called the Pentapolis, and 17 other towns situated chiefly on the Adriatic. From this time the popes in all their proceedings assumed the style of temporal sovereigns. Their authority, however, was little more than nominal until Charlemagne, having completed his father's work by the total destruction of the Lombard monarchy in 774, secured to the Roman pontiffs the exarchate of Ravenna, the island of Corsica, the provinces of Parma, Mantua, Venice, and Istria, and the duchies of Spoleto and Benevento. But with this new order of things arose a new source of dispute. Charlemagne was crowned by Pope Leo III. in 800 "emperor of the Romans," and for many years his successors continued to assert an imperial authority over Italy, which was retained in name by the German emperors down to the close of the 18th century. In the mean time, under cover of papal grants of territory to lay barons, a number of powerful families had

grown up in Rome and other dominions of the church, who considered themselves and acted as politically independent. Thus, between the pretensions of suzerainty of the emperors on the one hand, and the turbulence of factions and insubordination of petty princes on the other, the popes of the middle ages were incessantly involved in quarrels. Many of them were exiled, imprisoned, or put to death. Whatever party became for the time dominant raised its own favorite to the pontificate, and not unfrequently there were two or more claimants for the sacerdotal crown. Gregory VII. (Hildebrand), who reigned from 1073 to 1085, made the humiliation of the emperors the great aim of his pontificate; but his famous struggle with Henry IV. resulted in no accession of independence to the Roman states, though during his time an important addition was made to their extent by the countess Matilda of Tuscany, Parma, Modena, and Mantua, who granted all her territories to the pope, renewing the grant afterward to Paschal II. The emperors refused to acknowledge the papal claims, as Matilda being a vassal of the empire could not alienate her rights of sovereignty; and when Innocent III. came to the throne in 1198 he found the emperor real or nominal master of the whole of Italy, while the donations of Matilda were divided as fiefs among his generals. Innocent was the first pope who made his states really independent. After the death of Henry VI., being appointed guardian of that monarch's infant son Frederic II., and knowing that the people were ready to rebel against the oppressive administration of the German feudatories, he sent his legates to many of the principal cities and towns, and the inhabitants joyfully threw open their gates, took the oaths of allegiance, and received full guaranties of their municipal rights. Otho IV. afterward ceded to him the disputed territory of the countess Matilda, but having seized several of the pope's cities was excommunicated in 1210 and deposed. The enemies whom Innocent had now chiefly to fear were his own subjects. The feudal rights of the nobles and the municipal rights of the cities left him little direct authority; and in Rome especially, where the old democratic spirit showed itself in a system of government composed of a senate, consuls, popular assemblies, and a prefect for the administration of justice, his power was closely circumscribed. The senate was abolished about this time by the Romans themselves, and in its place a single officer was elected with the title of senator, and with control of the militia and judiciary. Innocent contrived to have an oath imposed upon this functionary to defend the rights of the Roman pontiff, and took into his own hands the appointment of the prefect, which had previously been exercised by the emperor. But in other parts of Italy the power of his feudatories was little if at all weakened. Bologna, Perugia, and Ancona were virtually republics; and although Pope Nicholas III. in 1278 ob-

tained from Rudolph of Hapsburg a recognition of the papal sovereignty over a certain specified territory, and a renunciation of all rights within the same which might still pertain to the imperial crown, the popes did not thereby acquire any real authority. In 1809 the papal residence was removed to Avignon, and the Roman states were torn by contending factions, of which the Guelphs were supported by the popes and the Ghibellines by the emperors. In the midst of these disorders Cola di Rienzi succeeded in establishing himself at Rome (1347), and with the title of tribune of the people enforced the laws, curbed the license of the barons, and restored peace and prosperity to the commonwealth. His reign, however, was short. Driven from Rome by the citizens, who had become disgusted with his arrogance, he languished several years in prison at Avignon, until the disorders in Italy became so violent that Pope Innocent VI. sent him back with the title of senator in 1354, in company with the legate Cardinal Gil Albornoz. Rienzi was received in triumph at Rome, but was killed in a popular insurrection at the end of 4 months. Albornoz gained several victories in the field, and reduced the Romagna, the Marches, and the Campagna to obedience; but his successes, owing partly to the interference of the Florentines, were only temporary. The confusion was increased soon after by the springing up of a series of anti-popes, who for many years divided with the legitimate pontiffs the obedience of the Christian world, appointed their own cardinals, and were sometimes in possession of Rome, whither the throne was carried back by Urban VI. in 1378. The schism was healed in 1417 by the council of Constance, which awarded the tiara to Martin V., and the Roman states began to enjoy a more regular form of government. Eugenius IV., however (1431-'47), was driven from his capital by a popular insurrection, and a short-lived republic was instituted, which his minister Vitelleschi suppressed with great cruelty. Alexander VI. (1492-1503) subdued the turbulent nobles of the Marches; and a still further advance toward the consolidation of the state was made by the warrior-pontiff Julius II. (1503-'18), who reduced the barons to obedience, joined the league of Cambrai with France, Austria, and Aragon against the Venetians, who had taken possession of Rimini, Ravenna, and other papal cities, and, having secured his objects, then united with Venice to expel the French. At the time of his death the great sources of disturbance in central Italy were the wars of the French and Spaniards in the N. and S. extremities of the peninsula. His successor Leo X. (1518-'21) not only restored peace, but made some additions to his territory, and earned a still better claim to greatness by a just and enlightened government of his own subjects. In many respects his reign may be called the golden age of the papal sovereignty, and from this time the States of the Church acquired a more com-

pact and homogeneous character than they had ever before possessed. Clement VII. (1523-'84) formed a league with Venice, France, and England against the emperor Charles V., which entailed numerous misfortunes upon him. Rome in 1527 was stormed and pillaged by the imperial troops under the famous constable de Bourbon, and the pope himself was 7 months a prisoner. Sixtus V. (1585-'90) was distinguished for his rigorous administration of justice, and was in all respects one of the most remarkable men of his age. He exterminated the outlaws who infested Rome and its environs. Ferrara was annexed to the Papal States during the reign of Clement VIII. (1597), the duchy of Urbino under that of Urban VIII. (1623), and the duchy of Castro and Ronciglione in the time of Innocent X. (1650). Under Clement XI. (1700-'21) the States of the Church were invaded by the Austrian archduke Charles, and Sicily, Sardinia, Parma, and Piacenza, ancient nominal fiefs of the holy see, were transferred to other hands. Clement XIII. (1758-'69) was deprived of Avignon, Benevento, and other places, and involved in contests with nearly every state in Europe on account of his protection of the Jesuits; but Clement XIV. (1769-'74) suppressed the obnoxious order, and recovered what his predecessor had lost. The liberality and virtues of his successor, Pius VI. (1774-'99), were no safeguard against the violence of revolutionary France; and after Bonaparte had wrested from him Bologna, Ferrara, and Ravenna, and added them to the Cisalpine republic, he was dethroned in Feb. 1798, and carried captive to France, where he died in the following year. In the mean time a republic was proclaimed at Rome by the French general Berthier, with a government consisting of consuls, senators, and tribunes; but it came to an end in 1799, when the army by which it was supported was beaten by the allies. In March, 1800, Pius VII. was elected at Venice, Rome being then in a state of anarchy; and in July, 1801, after the peace of Lunéville, he made a concordat with Bonaparte, who had now withdrawn his troops from all parts of the Papal States except the legations; these had been incorporated with the new Italian republic. The refusal of Pius VII. to expel from his dominions the subjects of all those powers who were at war with France led to a fresh invasion; in Feb. 1808, Bonaparte's troops took possession of Rome; in April, Ancona, Macerata, Fermo, and Urbino were united to the "kingdom of Italy;" in May, 1809, Napoleon declared the remainder of the Roman states annexed to the French empire; and soon afterward the pope was carried prisoner to France, and did not return to his capital until after the emperor's abdication (1814). The congress of Vienna restored to him all the territories of the church, and he devoted the rest of his life to reforming the administration after so many years of disorder. The pontificates of Leo XII. (1823-'9) and Pius VIII. (1829-'31) were comparatively tranquil; but Gregory

XVI. had scarcely ascended the throne in Feb. 1831, when an insurrection broke out in Bologna and other places, simultaneously with risings in various parts of Europe. By the assistance of Austrian troops the rebellion was soon suppressed. The present pope, Pius IX., was elected in 1846, and at once inaugurated a series of reforms and concessions which were hailed throughout Italy with the most intense enthusiasm. But the ultra liberals soon found that he was unwilling to go as far as they desired. Enthusiasm gave place to insults, and the revolution which broke out in France and northern Italy produced a powerful effect at Rome. Yielding to the popular movement, the pope in March, 1848, issued a proclamation promising a constitution on a liberal basis, with deliberative chambers, and at the same time formed a new cabinet composed of 10 laymen and only 8 ecclesiastics. Much against his will he was forced to take part with Charles Albert in hostilities against Austria; but the half organized force which marched from Rome to the Mincio cannot be said to have added much strength to the Italian army. In the mean time the people of Rome were rapidly taking all power out of the hands of the government, and in September it became necessary to construct a new ministry. Count Rossi, formerly French ambassador, and a moderate liberal, was intrusted with the department of the interior and finance, and Cardinal Soglia with the ministry of foreign affairs and presidency of the council. This produced for a time a good effect, but on Nov. 15, the day appointed for the opening of the chambers, Rossi was assassinated at the entrance of the legislative halls. With him the whole government fell. The next day the populace, assisted by the civic guard, forced their way into the Quirinal and compelled the pope to accept a radical ministry. Thenceforth he remained a prisoner in his palace, taking no part in the administration, and on the 24th he escaped in disguise to Gaëta in the kingdom of Naples. After some ineffectual negotiating to induce him to return, the chambers at Rome appointed a provisional government of 8 persons; the ministry of Mamiani was replaced by one still more democratic; a constituent assembly was called; the revolutionary party was reinforced by a large part of the Swiss troops in the papal service, and by a body of 8,000 men collected by Garibaldi; and on Feb. 18, 1849, the constituent assembly dethroned the pope and proclaimed a republic. The Roman states now entered heartily into the Italian war of independence, and when the revolutionists were driven from northern Italy by the Austrian arms became an asylum for the refugees. The government was nominally administered by Mazzini, Armellini, and Saffi, but the power was really shared between Mazzini, Garibaldi, and Avezzana. In the mean time, however, the French government had resolved upon restoring Pius IX. to his throne, and in April an army under

Gen. Oudinot landed at Civita Vecchia and immediately marched to Rome. A serious repulse which they experienced before the walls (April 20) was followed by an armistice, during which a Spanish auxiliary corps took possession of the S. provinces. On June 2 the siege was begun in form, and by July 1 the French were complete masters of the city. The pope appointed a council of state to carry on the government, promised further administrative reforms, and published an amnesty, though with many restrictions; but the chambers were not revived, and the pontiff did not return to his capital until April, 1850. The only effect of the revolution was to defeat the hopes of the liberal party, and induce the pope to adopt a much more conservative policy than he had shown in the beginning of his reign. Supported by the French army of occupation and by the Austrians who held the Romagna, the government succeeded in maintaining tranquillity until 1859, when the Italian war gave occasion for fresh symptoms of discontent. The withdrawal of the Austrian garrison from Bologna, June 12, was the signal for a peaceful revolt of the whole Romagna, and the organization of a provisional government, which offered the dictatorship to the king of Sardinia. Victor Emmanuel, without immediately accepting the sovereignty, intrusted the government of the revolted legations to Massimo d'Azeglio, and afterward to Signor Buoncompagni, and in March, 1860, formally declared them annexed to the Sardinian monarchy in accordance with a vote of the inhabitants. They constitute, with Parma and Modena, what are called the "Emilian provinces," from the ancient *Via Æmilia*, which traversed them. The rebellion had extended S. of the Apennines also, and an insurrection at Perugia was quelled by the Swiss troops (June 20) with much bloodshed. At Rome disorders took place March 19, 1860, but were suppressed without much difficulty. The pope enlisted a considerable force of foreign troops, a large number of whom were Irish, and offered the command of his army to the distinguished French general Lamoricière, who accepted the post in April. Early in September, following close upon the successes of Garibaldi in Sicily and Naples, revolt broke out in Urbino e Pesaro, Umbria, and the Marches, and the insurgents on the 11th placed themselves under the protection of Victor Emanuel. Accordingly a Sardinian force under Gen. Fanti took possession of Perugia and Spoleto, while Cialdini with 50,000 men made himself master of Pesaro and Urbino, and marched toward Ancona, where Lamoricière had concentrated the pontifical troops. After a siege of 7 days, the Sardinian fleet cooperating vigorously in the attack, the city capitulated Sept. 29, Lamoricière and the troops then with him becoming prisoners of war. On Oct. 18 the Sardinian legislative chambers passed a bill empowering the king to incorporate the Two Sicilies and the Papal States with his dominions. In No-

vember a vote of the population of the revolted provinces was taken on the subject of annexation to Sardinia, and resulted in an overwhelming majority in favor of that measure. Benevento and Ponte Corvo, being surrounded by Neapolitan territory, have also been dissevered from the Roman states in the course of the revolution in the kingdom of the Two Sicilies, and the hold of the pope upon his remaining provinces, now restricted mainly to those bordering on the Mediterranean, is extremely weak. The emperor Napoleon III. has proposed a voluntary surrender by his holiness of all his temporal dominions except the city of Rome and its immediate neighborhood—a proposition which Pius IX. rejected with considerable warmth.

PAPAGAYO, *GULF* or, an indentation on the Pacific coast of Nicaragua, between the bay of Salinas and Punta Desolada, so called from the baffling, revolving winds which beset it, and which in their course may be supposed to have some fanciful relation to the crooked beak of the parrot, in Spanish *papagayo*. These winds are occasioned by the trade winds from the Caribbean sea, which sweep entirely over the isthmus of Nicaragua, through the valley of the Nicaraguan lakes, where they encounter the sea breezes of the Pacific, producing the phenomenon referred to. The port of San Juan del Sur lies in the bight of this gulf, and hence is only accessible, with difficulty, by sailing vessels.

PAPAW (Fr. *papayer*, a name applied to the *asimina triloba* of Dunal), a North American tree 10 to 20 feet high, belonging to the natural order *anonaceæ* of Jussieu, tropical plants of which one genus alone belongs to the United States. There are several species, either small trees or shrubs, the roots and bark of which possess an extremely nauseous odor; leaves pubescent when young, alternate, destitute of stipules, distinctly articulated with the stem, entire; flowers axillary, mostly solitary; sepals 3 to 4, persistent, often united at the base; petals 6 in 2 rows, hypogynous, coriaceous; stamens indefinite, packed closely together on a hypogynous torus; filaments short; anthers adnate, exserted; ovaries commonly numerous; styles short or none; stigmas simple; ovules solitary or several erect; fruits consisting of dry or succulent carpels with one or many seeds, either distinct or concrete into a fleshy mass; seeds anatropous, testa brittle; embryo minute at the base of a hard ruminated albumen. The common papaw is described by Michaux as having its trunk covered with a silver-gray bark, which is smooth and even polished; the wood is spongy, extremely soft and destitute of strength, and applicable to no use in the mechanical arts; the leaves are borne on short petioles, and are alternate, 5 or 6 inches in length, and of an elongated form, widening from the base to the summit. They are of a fine texture, and the superior surface is smooth and brilliant. The flowers, which are attached

by short peduncles, are pendent and of a purple hue. When the fruit is ripe, it is about 8 inches long and $1\frac{1}{4}$ thick, of a yellowish color and of an oval form, irregular and swelling into inequalities. Its pulp is soft and of an insipid taste, and it contains several large stones. It is never brought into the markets, and is sought in the woods only by children. It is however described by some as esculent and very fragrant; and it is suggested by Dr. Darlington that, as it is said to be much improved by cultivation, it might be well to try what further and careful culture could effect. The common papaw is called by the Canadian French *assimnier*, the generic name given by Adanson being only a change from that. This species is not uncommon on banks of streams in the middle, southern, and western states; and in the rich valleys intersected by the western waters, it forms thickets exclusively occupying several acres. The small-flowered papaw (*A. parviflora*, Michaux's "Flora") is a small shrub rarely exceeding 2 feet in height, with a few branches near the summit; the young branches are clothed with a velvet-like ferruginous pubescence; leaves alternate, obovate, abruptly acute, and slightly acuminate, a little hairy on the upper surface, pubescent underneath, on very short petioles; flowers solitary, nearly sessile; calyx very pubescent, deciduous; corolla greenish purple, stamens shorter than the corolla; fruit about $1\frac{1}{4}$ inches long, irregularly oval. This species grows in sandy pastures along the sea coast of Carolina and Georgia. The *A. obovata* of Torrey and Gray is a shrub 1 to 2 feet high, with oblong-obovate, obtuse leaves, with a ferruginous tomentum beneath. Nuttall describes it as a very low shrub with whitish flowers equal to those of the glaucous magnolia. It occurs in the sandy woods of Georgia and Florida. Another species is the *A. pygmaea* (Mx.), a small shrub 6 to 18 inches high, with nearly sessile, coriaceous, persistent leaves, 4 to 6 inches long, very narrow and reticulate; flowers solitary, axillary, large, on short peduncles; petals reddish brown. It is found in sandy fields of Georgia and Florida.—The *anonaceæ* comprise, beside these comparatively insignificant fruits, the delicious custard apples of the East and West Indies, the cherimoyer of Peru, the sweetsop, &c. Martius in his *Flora Brasiliensis* (Tübingen, 1829-'33) has many interesting particulars concerning the order.

PAPER (Gr. *papyrus*, papyrus), a material prepared in thin sheets from vegetable pulp, and universally employed for writing and printing upon, taking the place of the articles used by the ancients for their writings. (See **PAPYRUS**, and **PARCHMENT**.) In the European countries papyrus, chiefly of Egyptian manufacture, continued in general use for some centuries after the Christian era. In the 5th century the city of Alexandria numbered this among its most profitable branches of manufacture, and it ranked with the chief items in the commerce of the

nations. Several varieties were known to the Romans, of which that most widely esteemed, until the introduction of the Claudian paper, was known as the Augustan paper. It was 13 fingers in breadth, such being the extreme length of the strips of papyrus of which the material was composed. The strips, exceedingly thin and delicate, crossed each other at right angles, and were compressed into one close sheet, being secured by a paste or sizing. The Claudian paper was made much stronger and better adapted for writing upon, by laying and cementing the fine thin strips upon a groundwork of the coarser kind of papyrus. Such paper continued in use down to the 11th century in Italy, and to the 13th in France, and was finally displaced by the *charta bombycina*, or paper made of cotton, the Greek word *βουβύνη* being in ancient times used either for silk or cotton. At what time raw cotton was first applied to this use is not known. Montfaucon mentions having seen a manuscript of this paper of the date of 1050; but it is supposed the European manufacture of paper from the pulp of vegetable fibres may be dated full 50 years earlier than this. It appears to have been introduced into Europe from the East, through the Arabians and Persians. The inhabitants of several Asiatic countries have long manufactured paper from a variety of materials; and the Chinese are said to have varieties peculiar to almost every province, the processes for producing which are no doubt very ancient. They employ the inner bark of different sorts of trees, the pulp made of which they compress into thin sheets. In the province of Se-chuen, it is said, they make paper of linen rags, as it is made in Europe; and in Fo-kien they use the young bamboo. This very fibrous material is cut into pieces several feet long, is well macerated several days in water, then dried under a covering of quicklime, which is watered at the time to cause it to slake. It is then washed, cut into filaments, dried and bleached in the sun, boiled in water, and reduced to a pulp by beating the substance in a wooden mortar. A glutinous vegetable extract is then mixed with the pulp, and being thoroughly incorporated with it by beating in mortars, the mixture is poured into tubs in the condition of a viscid semi-fluid. From this the workmen withdraw enough at a time for a sheet of paper, which is formed and partially dried in a mould, and when removed from this the drying is completed upon the surface of hot air pipes, as the flues from a stove. To prepare it for writing upon, it is sized by dipping it into a solution of alum. The Chinese rice paper is prepared from the inner portion of the stems of the *aschynomene pulidosa* (Roxburgh), a hardy leguminous plant, which grows abundantly on the marshy plains of Bengal, and about the lakes near Calcutta. The stems are rarely more than 2 inches through. They are exported in large quantities from the island of Formosa to China and Calcutta. The stems being cut into proper lengths for the sheets,

the pith is cut spirally around into a thin slice after the manner of cutting cori, an operation requiring a knife with a very keen edge. The sheets, which are sometimes a foot long and 5 inches wide, are spread out and compressed into the form of paper. The material on being wetted swells and retains a raised surface which gives to the drawings made upon it a pleasing effect of relief. The inferior sorts are largely used for making artificial flowers. The paper of the best qualities is chiefly used for paintings of birds, flowers, insects, &c., for which purpose the original sketch is made of a deep black upon other paper, and the rice paper being laid upon this, the paints are applied to its surface. This paper is well adapted for lithographic printing; other silky varieties are equally well suited for steel and copper plates. The Japanese manufacture varieties of paper from the inner-bark of 4 or more species of trees, one of which is the *morus papiifera sativa* or true paper tree. Their processes exhibit great skill and care, and some of the paper they prepare is remarkable for its strength, which is so great that it may be used for many of the purposes of textile fabrics, and indeed resembles silk and woollen stuffs so closely as to be sometimes mistaken for them.—According to Gibbon, the art of manufacturing paper was derived from the manufacturers of Samarcand, where it was introduced from China in the year 651, and thence spread over Europe; and he adds, on the authority of the librarian Casiri, in the *Bibliotheca Arabico-Hispana*, that paper was introduced at Mecca in 707. Linen rags appear to have been used at a somewhat later period than cotton, and in Spain, particularly in the provinces of Valencia and Catalonia, where linen abounded, the manufacture of paper from this material was probably commenced at an early period. The oldest specimen of linen paper in Spain having a date is said to be a treaty of peace between the kings of Aragon and Spain of 1178. As stated in the "Chronology of Paper and Paper Making," by J. Munsell (Albany, 1857), paper mills were in operation at Toledo in Spain in 1085, making paper from rags with the use of moulds for forming the sheets; and in 1151 the best paper was made at Xativa from raw cotton and rags, which were reduced to pulp by stamping them in mills instead of grinding after the Moorish method. In France the manufacture dates as far back as 1814, and about the same time in Germany; and in Italy it was conducted in 1367. Linen paper seems to have been common in Germany in 1824 and afterward. Paper was known in England in the time of Edward II.; but parchment or vellum was the writing material commonly employed. It was manufactured in England as early as the reign of Henry VII.; but the first mill of which there is any particular account is one built in Dartford in Kent, by a German named John Spilman or Spielman, jeweller to Queen Elizabeth. This is celebrated in a poem on paper of the date of 1598. The business

made but slow progress, and during the 17th century the supplies were chiefly from France, which country, with Holland and Genoa, maintained a decided superiority in this production. The qualities of the various papers produced are compared by Fuller in 1661 to those of the people that manufactured them; the French being "light, slight, and slender; the Venetian neat, subtil, and court-like; and the Dutch thick, corpulent, and gross, sucking up the ink with the sponginess thereof." In England great improvements were introduced by the French refugees of 1685; and from this time the business advanced in importance. In 1690 particular attention began to be directed to the production of white paper, almost all that was previously made being brown. The total annual value of the product at the close of the century did not exceed £28,000, and the number of mills in all England was less than 100. In 1721 there were produced about 800,000 reams, which was about $\frac{1}{3}$ of the total consumption; and two years afterward the value of the yearly product was estimated at £780,000. In the middle of the century the importations from Rouen in France had decreased to such an extent, that many of the French paper mills were abandoned or converted to other uses. The celebrated manufacturer James Whatman had his mill in operation at Maidstone in 1760; and from that time to the present its product has been famous for its superior quality. A medal was awarded for it in the great exhibition of 1851 to his successors. About the same period important improvements were made in the manufacture in Holland and Germany. Cylinders armed with steel blades for reducing the pulp were substituted by the Dutch, about the year 1750, for the stampers which were before in use. They were run with far greater ease by their windmills, and proved much more effectual. The French academy of sciences sent an agent in 1768 to Holland to visit the paper mills and investigate the processes in use. The Germans attempted the use of straw in 1756; and in France in 1776 a book was printed upon paper of good white appearance made from the bark of the linden (basswood). The greatest advances in the manufacture were now made by the French. In 1798 Louis Robert, a workman in the establishment of M. Pierre François Didot at Essonne, announced that he had discovered a new way of making, by the labor of one man only, sheets of paper of very large size, even 12 feet wide and 50 feet long. This was by means of an endless web, and the machine as afterward perfected in England became the most important piece of apparatus in the manufacture of paper. Robert obtained a patent right from the French government and an appropriation of 8,000 francs. The Messrs. Fourdrinier, a wealthy firm of stationers and booksellers in London, who purchased the right for Great Britain, expended £60,000 in matters connected with the improvement and manufacture of the machine,

and were made bankrupt before they could realize the dues to which they were entitled for its use. In 1800 good white paper to the amount of 700 reams a week was made for the first time from old waste and written and printed paper, such as had always before been thrown away. This was done in England by Matthias Koops. He also made better paper from straw, wood, and other vegetable matters, without the addition of any other known paper stuff, than had ever before been produced. He obtained a patent for the use of straw, hay, thistles, waste and refuse of hemp and flax, &c.—In the United States the first paper mill of which we have any account was erected in 1714 upon Chester creek in Delaware. It was afterward owned by a Mr. Wilcox, who furnished Franklin with paper from it. The mill is still in operation, belonging to a son of Mr. Wilcox, and paper is made in it by hand on the same process which was in use a century ago. In the colony of Massachusetts Bay, as appears from the statement of Salmon in his "Modern History" (vol. iii. p. 494), a paper mill was set up about the year 1717, and in 1720 was making paper to the value of about £200 per annum. But other authorities give the year 1780 as the date of the first paper mill in Massachusetts, which was built at Milton under the encouragement of the bounty offered by the legislature in 1728. Mr. Daniel Henchman of Boston, who it is supposed built this mill, exhibited a sample of his paper before the general court in 1731. There was in 1728 a paper mill at Elizabethtown, N. J., owned by Mr. William Bradford. The Massachusetts mill appears to have been stopped for some time, as is supposed for want of competent workmen; and in 1760 it was started again by a British soldier stationed at Boston, for whom a furlough had been obtained long enough for this purpose. In 1768 a mill was completed at Norwich, Conn., by Christopher Leffingwell, under official encouragement. Another was in operation in 1776 at East Hartford, belonging to Watson and Ledyard, which supplied about 8,000 sheets weekly for the press at Hartford, and most of the writing paper used in the state and the continental army. There were at this time three small mills in Massachusetts, and one in Rhode Island, and not long after one at Bennington, Vt. The manufacture had made much more rapid progress in Pennsylvania, New Jersey, and Delaware, where in 1770 the total number of paper mills was about 40, and the annual product of paper was worth about £100,000. In New England and New York the supply was far short of the demand; and it was with the greatest difficulty that rags were procured for the mills. The people were not accustomed to preserve them, and though advertisements announced when the bell carts would go round to collect, and urgent appeals in prose and verse were made to the patriotism of the ladies, accompanied with offers of 8d. per pound for clean white cotton or linen rags, and 2d. for white,

blue, brown, and check, the quantities obtained were very meagre. The first paper mill in northern New York was built in 1793 at Troy by Messrs. Websters, Ensign, and Seymour, in which from 5 to 10 reams were made daily. The next year one was constructed at Fairhaven, Vt., by Col. Lyon, and the bark of the basswood was employed in it for making wrapping paper. In New England and New York, mills built for other purposes, as grist mills, began to be converted into paper mills; but the greatest difficulty was experienced in procuring rags. The printing offices could not be furnished with the supplies they required; and in 1804 the American company of booksellers offered premiums to any one who would make the greatest quantity of paper from other materials than cotton and linen rags. In 1810 the number of mills in the United States was estimated at 185, of which 7 were in New Hampshire, 38 in Massachusetts, 4 in Rhode Island, 17 in Connecticut, 9 in Vermont, 28 in New York, 60 in Pennsylvania, 4 in Delaware, 8 in Maryland, 4 in Virginia, 1 in South Carolina, 6 in Kentucky, and 4 in Tennessee. They produced 50,000 reams of paper worth \$3 per ream, weighing about 500 tons; 70,000 reams of book paper at \$3.50, weighing 680 tons; 111,000 reams of writing paper at \$3, about 650 tons; and 100,000 reams of wrapping paper, at 83 cts.; also paper hangings and other articles. At this time rags began to be imported largely into the United States from Europe. Each mill, as ordinarily constructed in Massachusetts, had 2 vats, and made from 2,000 to 3,000 reams of the different sorts of paper. It required a capital of about \$10,000, and employed 12 persons or more. The materials used were chiefly rags, old sails, and junk. Steam power was first applied to this manufacture in the United States at Pittsburg in 1816; the engine was of 16 horse power, and the annual product of paper was worth \$20,000. In 1820 the annual value of the paper manufactures in the United States was rated at \$3,000,000. In 1822 the publication of Rees's "Cyclopædia" in Philadelphia consumed 80,000 reams of paper. This was the largest work in the English language. The most extensive paper mill in the United States in 1825 was that of Messrs. D. and J. Ames at Springfield. In 1828 the consumption of paper for the newspapers throughout the country was estimated at 104,400 reams, costing \$500,000. The total value of the product was nearly \$7,000,000, and of the rags and other materials employed in the manufacture about \$2,000,000. The Fourdrinier machine, imported from England, was in use in a number of mills, Massachusetts in 1829 having 6 of them, or one for every 10 mills. These, and improved methods of cleansing and bleaching, principally by the use of chlorine, gave a great impulse to the business, and rendered the coarser materials available for the manufacture of the better qualities of paper. The importation of rags

continued to increase, their value in 1839 and 1840 exceeding \$560,000 a year; the imports of paper in each of the same years amounted to about \$150,000, and the exports to about \$85,000. In 1850 the value of the rags imported was \$748,707, and of paper \$496,563. Three fourths of the rags were from Italian and Austrian ports, and their cost was \$3.61 for 100 lbs. The capital invested in the manufacture was about \$18,000,000, the annual product of paper about \$17,000,000, and the number of mills about 700. All but two of them were provided with the Fourdrinier machine. The town of Lee in Berkshire co., Mass., became celebrated for its paper mills, having 25 mills in 1851, which produced about 25,000 lbs. of paper daily, and \$2,000,000 worth per annum. The consumption of paper in 1852 equalled in amount that of England and France together. The exports of paper and stationery continued small, but the imports for the year ending June 30, 1853, amounted to \$602,659, and of rags to \$982,887, costing \$4.31 for 100 lbs. The number of mills in active operation in 1854 is stated to have been 750, producing annually about 250,000,000 lbs. of paper, worth \$25,000,000, and consuming 405,000,000 lbs. of rags, which cost about 4 cents a pound. The demand, however, still exceeded the supply, so that the price in 1854 advanced 2½ cts. per pound, causing several of the newspapers in New York and Philadelphia either to increase their rates or reduce their size. Experiments in introducing new materials for the manufacture had proved successful as to basswood; and at Little Falls, N. Y., a large and very superior mill was built by the ligneous paper company to use this material alone. At Norwich, Conn., the mills of the Chelsea manufacturing company were producing in 1856 at the rate of 7 tons of paper in a day. The Pacific mills of Windsor Locks in the same state are about as extensive, and are probably not exceeded in their capacity by any mills in the world. The total amount produced in the United States at this time was about 200,000 tons per annum; in Great Britain 66,000 tons; and in France 70,000 tons. The consumption by the large publishing houses is immense, that of a single newspaper, the "New York Tribune," being about 570,000 sheets or 80 tons a week. This is chiefly supplied by a mill at Niagara falls. The "London Times," using a much heavier paper, consumes 9 tons or 90,000 sheets daily.—The materials suitable for the manufacture of paper are all those vegetable fibres which have a corrugated edge and may be macerated into a pulp with water; and those are to be preferred which, while they can be obtained in the greatest abundance at the least cost, can also be converted with least labor into pulp. Nothing has yet been found better adapted for this manufacture than the fibres of cotton and flax, and these are obtained most cheaply after they have served their original purpose, and in the form of rags are discarded from further service. By reason

of the wear to which the fibres have been subjected, and their washings in alkaline waters, the material is already partially prepared for reduction to pulp. The varieties of white paper employed for printing and writing until within the last 10 years were prepared almost exclusively from rags of cotton and linen; while the cheaper brown and colored wrapping papers were manufactured, as they still are, from coarser materials, such as the waste of rope manufactories and of cotton mills. By recent improvements these are found to be applicable to the manufacture of the finest white paper, and even tissue paper; and such are now produced on a large scale in the paper mills of the United States. The large establishment of Messrs. H. V. Butler and co. at Paterson, N. J., consumes cotton waste, hempen bale ropes, and bagging exclusively, and no works produce paper of superior qualities. The brown papers made in American mills from these materials combined together is unequalled by any similar papers made in Europe. Still coarser papers are made of the fibres of the worn-out India bagging, which in Great Britain especially is obtained in immense quantities, and is there largely appropriated to this use. (See COIR, GUNNY, and JUTE.) Straw is used also to a considerable extent, especially in England, as an auxiliary to rags; and when mixed with them, its fibre gives stiffness to the paper, which is largely used for newspapers. The stalk of the straw contains silica, which must be removed by long boiling in a strong alkaline lye, and thus the cost of the preparation of the material is necessarily greater than that of rags, which require much shorter treatment of this character; and its fibre moreover is short and tender. In the United States the cane or reed of the southern swamps offers itself as a fibrous material that can be procured at little cost in unlimited quantities. Various attempts have been made to convert this into paper, and with some success. At a mill a few miles N. from Baltimore considerable paper has been made from it, and samples have also been exhibited in St. Louis, Mo.; and the success is considered so decided that mills are now in process of construction at Wilmington, N. C., for preparing the fibre upon a large scale for supplying paper mills. The reeds freed from their joints are boiled under pressure in alkaline solutions, and the product is afterward bleached as in the ordinary process. By another American process a singular expedient was adopted for reducing the material to fibres. The long canes were introduced into iron cylinders of great strength so made as to be closed steam-tight. Steam was then forced in under great pressure, and the end of the cylinder corresponding to the muzzle being suddenly opened, the canes were shot out as from a gun and torn into slender filaments. Around the cylinder the silica that constituted a considerable part of the hard outer covering of the canes collected in piles of snow-white and apparently perfectly

pure material. A similar plan has been employed in tearing to pieces logs of bass or white wood, which furnishes a fibre adapted for the production of paper. Prepared in other ways, basswood is now in use in some of the mills of northern New York. Its fibre is however rather weak and short, and tends to fall to powder in its reduction to pulp. Paper made from the wood of the hemlock has recently been introduced to some extent for newspapers.—Numerous other vegetable substances have been carefully subjected to practical tests and converted to some extent into paper, several of which have been named in the account already given of the progress of the manufacture. In the Smithsonian institution there is a copy of a work by Jakob Christian Schäffer on experiments in making paper from other materials than rags (Erlangen, 1772), which is printed on more than 60 varieties of paper made from as many different materials. The works of the marquis de Villette, published in London in 1786 in 24mo., are printed on paper made of marsh mallow; and at the end are single leaves of paper manufactured at Bruges from 20 different species of plants, including the nettle, hops, moss, reed, several kinds of trees, herbs, &c. Mr. Munsell, in his work referred to above, enumerates 108 substances which have been experimented upon. They are chiefly vegetable matters; but among them are some animal and a few mineral substances. The chief dependence of the manufacture, however, is first upon rags; then upon the waste of cotton mills and rope factories; and then upon straw and basswood.—In the manufacture of paper, the first object is to prepare the raw materials for the processes by which they are brought into a pulpy condition. This is effected by various methods, which vary somewhat with the character of the materials. Rags are first cut into narrow strips by women, who sit each at a small table having a wire network surface and furnished with a large vertical knife blade, the back of which is toward the operator. The rags are cut by drawing them across this knife, and all hard substances, as buttons, hooks and eyes, and pieces of woollen and silk, are separated and laid aside, while the rags are thrown according to their characters into the appropriate compartments of a box placed conveniently at hand to receive them. Much dirt and sand falls through the netting. The next process, where the rags are not picked out or "overhauled," is the willowing and dusting. In cylindrical-shaped machines the rags are tossed about and thoroughly tumbled by the long teeth upon the revolving cylinders and against the fixed teeth set in the outer casing, whereby they are freed from the loose dirt and made ready for the boiling process. For this an alkaline solution is used, of variable composition according to the nature of the rags, the more highly colored requiring strong lye. For 100 lbs. of rags from 6 to 10 lbs. of carbonate of soda is used, and half as much

quicklime. The lye reduces the fine hard particles of the vegetable fibre, which if allowed to remain would cause knobby places in the paper, removes much of the dirt that still adheres to the rags, and partially whitens them. The solution is best heated by means of steam pipes, and various plans have been devised of accomplishing the object most efficiently, so as to subject all portions alike to the action of the lye. Large cylindrical iron boilers, set horizontally and made to revolve, were first employed by Mr. H. V. Butler of Paterson, N. J., and in various modifications have since been introduced into the best mills of Europe and the United States. These are provided with compartments perforated with holes for draining off the water, and they are charged at the ends with several hundred weight of rags at a time, when steam is admitted under a pressure of 60 lbs. or more per square inch. By the use of high steam, a saving of the soda introduced to facilitate the cleansing, as well as of much time, is effected. The operation for the full charge is completed in 8 to 10 hours. The rags are then ready for the process by which they are converted into pulp. This used to be effected by allowing the rags to ferment several weeks in stone vats, and then beating them with stamps or pestles in a wooden mortar. The mortar had a cavity in the bottom covered with a thick iron plate grooved on the upper surface, and the under sides of the stamps were also grooved. A hole through the mortar allowed the dirty water to escape from the cavity, while the fibres of the rags were arrested by a hair cloth covering. The machine known as the "engine," invented by the Dutch, took the place of the mortar, and is now in general use. Two kinds are employed, called respectively the washer and the beater, both constructed upon the same plan, the one designed for washing the rags, and the other for rubbing and reducing them to pulp. The latter may be placed below the former, and receive the rags directly from it; but usually they are separated by the bleaching apparatus and process. Each is a trough, it may be 10 feet long by $4\frac{1}{2}$ wide and $2\frac{1}{2}$ deep, cast in one piece of iron with the ends rounded, and provided with a longitudinal vertical partition that reaches within 2 feet of each end. The trough is thus divided into two chambers, which connect together at the ends. Across the middle of the cistern a shaft is set which carries a solid wooden cylinder in one of the divisions, and which can be raised or lowered about an inch by means of a screw at one end of the "lighter" or lever beam upon which the end of the axle rests. This cylinder is armed with about 40 longitudinal steel ribs or bars in a washer, and 60 in a beater, which project about 2 inches from its surface. Under the cylinder another set of steel bars, each of them from $\frac{1}{2}$ to $\frac{3}{4}$ inch thick, arranged in a segment of about 6 inches width, conforming to the curve of the cylinder, is firmly secured in the floor of the cistern. These bars, forming

the "plate," are bent in the middle, so as to make a slight angle with the bars of the roll, by which means the fibre is drawn out and reduced in length by a shearing action. The floor of the cistern rises up toward the cylinder, and behind the plate is continued up so as to form a breasting, the top of which is nearly as high as the centre of the cylinder. From this point it slopes rapidly down to the bottom of the trough, forming what is called the "back fall." The cistern being filled with water sufficiently to immerse the lower bars on the cylinder when this is raised up, the rags are introduced and spread about with the hand, and the cylinder is made to revolve. This causes a current to flow which moves the rags along with it, bringing them under the cylinder, and carrying them around the partition, till they are brought again between the ribs of the cylinder and those of the plate beneath. As the operation goes on, the cylinder is gradually lowered, till toward the last, when the rags have been worn down into the pulpy condition known as half stuff, the space is narrowed till the cylinder almost touches the plate. Before reaching this point, when the rags are coarse and offer considerable resistance in being drawn through the space, the motion, as the cylinder revolves with great rapidity, is very rough and jerking; but in the course of 3 or 4 hours it becomes steady, indicating a thorough reduction of the material to pulp. A box cover is constructed over the cylinder to prevent its throwing out the contents of the trough by the rapidity of its revolution. During the operation fresh water, which should be perfectly clean and pure, is continually admitted, and the dirty water is removed by some one of the several contrivances that have been devised to take it up and leave all the fibre behind. That in general use consists of hollow cylinders covered with very fine wire cloth, and made to revolve slowly in the current of pulp, as it passes through the other compartment after leaving that occupied by the washing cylinder. Inside the cylinder the water is caught in buckets, and being raised up in them is discharged into a tube which passes through the axis of the cylinder, and thus it escapes from the machine. In this process much importance is attached to the condition of the bars on the cylinders and plates, care being taken that they are adapted to the particular work, and are kept in good order, so that the rags are rubbed rather than cut into pulp. Only by giving plenty of time to the operation is the material brought into the proper consistency, incorporating with it sufficient water. If the work is not done in this manner, good paper cannot be produced from the pulp. The time expended in properly washing a charge of from one to two cwt. of rags should be from 3 to 4 hours; but the operation is often completed in less time, to the detriment of the paper. The number of engines in a paper mill is commonly referred to as indicating its capacity. The power

required for running each cylinder toward the close of the process, when the space between its under surface and the plate is narrowest, is about equal to that of 7 horses. From this machine the half stuff is allowed to flow out by a large pipe in the bottom to the draining chest, where, being freed from much of the water it contains, it next enters the stone cisterns in which the bleaching is effected. In these a solution of chloride of lime, prepared with about one pound of the salt to 2 gallons of water, is employed. The liquor drains off through plates of zinc in the bottom, which are perforated with minute holes, and is then pumped up again and used with additions of strong fresh liquor. By 24 hours' steeping the pulp is converted to a nearly pure white color; and it is then removed sometimes to a strong iron box, in which it is subjected to the action of a hydraulic press for the purpose of forcing out most of the chlorine water, or goes directly to the beating engine, like the washing engine already described. In this the stuff is first run for half an hour or more with the cylinder raised, so as not to rub the pulp. The action is hence merely that of washing, and the effect is to remove the chlorine, which if allowed to remain would render the paper brittle and liable to soon crumble to dust. The salt hyposulphite of soda, technically termed "antichlor," is of late advantageously introduced to neutralize the chlorine and expedite its removal. Suitable mixtures are then added for sizing, according to the quality of paper to be made; and also any coloring matter. The ordinary size is a combination of soda and rosin to form a soap from which the rosin is precipitated upon the pulp by the subsequent addition of alum. The cylinder is then lowered and the pulp is ground by its action to a much finer consistency, its quality depending upon the judicious management of the cylinder, as not letting it down too fast nor too much at once. The beating is completed in $3\frac{1}{2}$ to 4 hours; and the stuff is then discharged into a large receiving vat. An improvement upon the Dutch engine has been invented by Mr. Joseph Kingsland of New Jersey, which is in successful use in this country and in England. It consists in a revolving grinder placed between two stationary grinders, the pulp being made to flow first through the space on one side and then through that on the other side of the revolving grinder, after which it is discharged in a constant stream. The revolving grinder makes about 200 revolutions in a minute, and the spaces are adjusted by screws for coarse or fine pulp as may be required.—The pulp being collected in stone vats, from which it is to be taken out for converting into sheets, is agitated by a stirrer to keep it of uniform consistency. By the old process of hand making, which is not yet entirely abandoned, it is then dipped out and moulded by a workman, called the vatman. The mould which he uses, holding it in both hands, is a shallow mahogany box some-

what larger than the sheet of paper, covered with parallel wires placed near together, and crossed by a few others.* A loose frame called a deckle, of the exact size of the mould, is held down upon its upper surface, serving as a margin to the wires, and determines the size of the sheet. A proper quantity of pulp being dipped up and shaken with a peculiar motion acquired by experience, the fibre is spread evenly over the wires and the water in great part flows through. The vatman then slips off and retains the deckle as he slides the mould along the edges of the vat to another workman called the coucher, and taking another mould to which he adjusts the deckle, he repeats the operation. The coucher meantime sets the mould on its edge to drain while he arranges on the table close by a sheet of felt cloth on which he lays the sheet of fibre by overturning the mould. This is returned to the vatman, who passes along another mould and sheet, and this is laid upon another felt with which the first sheet is covered. About 180 sheets are thus piled up alternately with as many felts, and the whole pile is then slipped under a press, by the action of which much water is squeezed out and the sheets acquire tenacity. These are then separated and piled up by themselves, and again pressed; and being again separated, or parted, they are piled and pressed a third time. Thus the marks of the felts are removed, and the paper is in good condition for drying, which is effected by hanging the sheets on hair lines in lofts or rooms specially devoted to this purpose. In favorable weather the drying may be completed in 24 hours, after which the paper is sized by dipping it several times in a preparation of glue and alum. The sheets are again pressed to remove the superfluous size, and are returned to the drying rooms, where they are suspended upon the lines and dried much more gradually than before, several days' time being requisite for the size to become well incorporated with the paper. The finishing is effected by passing the sheets laid alternately with glazed paper boards with some hot metal plates interspersed through the piles. This gives the name of "hot-pressed." It may instead be rolled with smooth copper plates between the sheets. By this method it was often 8 weeks before the paper was finally finished from the first treatment of the rags, and for every vat, from which about 150 lbs. of paper might be made in a day, there were employed 8 men and about as many women. The "water mark" upon paper, used to designate the peculiar kinds, is produced by coarse wires of the required figures attached to the moulds, so as to cause the layer of fibre to be somewhat thinner on their lines. Various devices formerly made use of in this way gave names to the sorts of paper to which they were applied, and the papers have retained these names. Thus "cap" or

* With the wires thus arranged, the paper produced is called "laid paper;" but with a woven wire cloth the product is known as "wove paper."

"foolscap paper" was so called from the water mark representing a fool's cap and bells; post paper, from the design of a postman's horn. What was called "pot paper" had the design of a pot or jug, and "hand paper" was distinguished by the figure of a hand. Water marks upon commercial papers, as bank notes, checks, &c., serve a useful purpose in rendering forgeries more difficult.—The Fourdrinier machine introduced extraordinary improvements over the old hand method of making paper. By means of it the capacity of production is immensely multiplied at greatly reduced cost. Paper is made in sheets of any desired size and of uniform thickness. Light tissue papers are produced by it which could not have been made by hand. The processes of sorting, trimming, and hanging up the sheets to dry, and the waste attending these handlings of the paper, are avoided; and what required weeks to effect is now accomplished in as many minutes. The cast-off rags of the poorest of the poor, as stated by Richard Herring in his "Paper and Paper Making" (London, 1856), may be forwarded after sunrise many miles, and be returned before sunset converted into sheets of the most perfect paper. But this wonderful rapidity in the manufacture is unfavorable to the production of paper of the greatest strength and durability. This is attained only by conducting each one of the numerous processes, from the trituration of the rags to the calendering, slowly and thoroughly. Mr. Herring exhibits among the samples in his work one specimen of paper thus carefully prepared, not much thicker than ordinary printing paper, which is almost as tough and durable as parchment, and capable of sustaining by a strip not wider than a bank note a weight of 200 lbs. It is impossible to convey a clear idea of the machine without drawings. At its head is placed a receiving vat into which the pulp is constantly supplied, and in which it is kept of uniform consistency by continual stirring. From the vat it flows out through a stopcock regulated to supply the quantity suited to the thickness of paper to be made; or the delivery is controlled either by pumps or by pulp meters contrived to supply equal quantities in equal times. Flowing then upon a lifter wheel, the pulp is diluted with water drained from the web of paper in advance of this part of the apparatus and brought back to the lifter wheel. By this wheel the mixture is delivered into the trough called the sand trap, which is 20 to 40 feet long and 4 or 5 inches deep. In this any particles of sand present settle, and the pulp passes through the strainer, which is arranged along one side of the trough. This is a box made of brass plates, those forming the bottom being perforated by fine slits, or the bottom is made of polished bars of brass, which are set almost in contact. The passage of the pulp through the narrow openings is facilitated either by a rapid jarring movement communicated to the strainer, or by an exhaust apparatus kept in opera-

tion beneath it. Knots, and any foreign hard substances that may be present, are caught on the strainer. Formerly such matters were picked out from the paper by hand while it was undergoing the drying process; this caused much damage to the sheets, and the knobby points that escaped notice seriously injured the paper, especially for the use of engravers. The pulp flows from the strainer into a vat which is as long as the width of the sheet to be produced, and along the whole length of one side of this vat it passes out over an apron upon the "wire"—an endless web of wire cloth, having from 3,500 to 5,000 holes to the square inch. It is supported by rollers, upon which it is carried constantly round at the rate of 25 to 60 or 70 feet per minute. The upper surface upon which the pulp is delivered is perfectly level, and may be 15 feet in length. A lateral jarring motion is communicated to the web, which shakes the fibres of the pulp together, and the water with some fibre dust passing through is caught in the "save-all" trough and returned to the lifter wheel. The width the pulp occupies on the wire is controlled by flexible straps or decks, one on each side, which, being adjusted to the width of the paper to be made, move along with the upper surface of the wire and return above it by an independent set of rollers. These decks are made of several layers of linen or cotton gummed, or of vulcanized rubber. The sheet of pulp as it becomes freed from water acquires consistency, and this is increased by the weight of a cylinder under which it passes, called the dandy roll. The friction causes this roll to revolve, and any designs for water mark or lines, made of fine wire and sewed upon its surface, are transferred to the sheet. For making laid paper the wires are laid longitudinally and very close together. The impressions are made more permanent through the action of suction boxes placed under the web at this point, which suddenly extract much of the water in the pulp and give to the sheet consistency enough to admit of its retaining the marks impressed upon it. Passing the suction boxes, the web reaches the couch rolls. These are rollers covered with felt, the under one carrying the wire, and the upper directly over it pressing down upon the web of paper and wire. The wire cloth going round the lower roller and passing beneath the save-all trough on its return to the supply trough, the web now leaves it, being taken on the surface of an endless blanket or felt, when, still in a very wet state, it is passed, with the felt on which it is supported, between a pair of heavy cast iron or brass rollers, by which it is compressed and freed from most of the water it has retained. In order to remove the impression left by the felt, the web is conducted away from this one and round a roller, having now sufficient tenacity to support itself; and being turned completely over, what was the upper side is received upon another revolving felt, and both

are carried between another pair of press rolls, the face of the upper one coming in direct contact with that surface of the paper which before rested upon the felt. The sheet goes next upon the drying cylinders. These are hollow, made of cast iron, and are heated by steam introduced into their interior. Their number and arrangement vary at the different mills, some employing as many as 20 of them. The first which receives the paper is moderately warm, and the heat increases with each one. By thus gradually drying the paper, it acquires greater strength than it would have if passed over a few hot cylinders. From these cylinders the sheet is wound directly upon a reel, or it may be passed through several sets of calender rolls by which its surface is smoothed and finished. The sizing for printing paper is usually produced by mixing the materials in the pulp as already described; but the finest writing papers are now sized almost altogether in the web, this being passed through a solution of gelatine and alum kept at a temperature of about 100° F., and dried immediately by running it over a series of open-work drums, through the centre of each of which a revolving fan creates a rapid movement of the air against the paper, causing, in a temperature kept at about 80°, a rapid drying. The old-fashioned way of drying writing papers in the loft is not abandoned in many of the best mills. The sheets are cut off for this purpose immediately after sizing. Paper thus dried is stronger, the straining effect of drying upon machines being avoided. The sheet is usually made about 54 inches wide, and it is run off by the machine at the rate it may be of 600 yards an hour, or a mile every 8 hours. It is cut into small sheets by different contrivances, applied to the paper either as it comes from the machine, or as it is wound off from the reels. It is cut lengthwise by pairs of circular knives, which revolve, one knife below and a larger one above the sheet, as it moves between them, and their cutting action is like that of scissors. To cut it across, two knives, one fixed and one movable, are made to work together like scissors blades at the instant when the right length of paper is brought forward by a drum and held fast by two long blocks being brought together and pressing the paper between them. The drum at the same instant retrogrades to take forward the length for the next sheet. The slack of the web, which is necessary in this interrupted movement, is kept up by what is called a dancing roll. The glazed surface given to the highly finished writing papers is produced by rolling the sheets placed in a pile with polished sheets of copper, with which they alternate. The operation is repeated many times to produce the best effect. Beside the cost of the process in the extra labor, a considerable loss is incurred by unavoidable damage to more or less of the paper, and by bringing strongly out defects which would escape notice in ordinary

paper.—The varieties of paper are numerous. They may be classed in general as writing (including drawing), printing, and wrapping; and beside these are the filtering and blotting papers, which differ from the other kinds in an admixture of woollen rags, by which the product is rendered absorbent. Cartridge paper is a thick variety of white paper used for making cartridges. Bank note paper is a very strong, flexible, and thin paper, made of the best linen rags; and tissue paper is a thin transparent paper used chiefly for tracing drawings, &c. The distinctions of the varieties of writing paper are based on the paper being wove or laid, and on the shades of color and degree of finish. The cream laid and cream wove are of a slightly yellowish white, and are now regarded as the choicest varieties. Papers of a bluish tint are prepared by mixing ultramarine with the pulp. A very small amount of ultramarine counteracts the natural yellow color, and produces the nearest approach to white. The light buff color is produced by oxide of iron of a low degree of oxidation, and paper of this shade has been recommended as more grateful to the eye than the glaring surface of the white varieties. As it is in reading and writing that injury most frequently comes to the eye, this suggestion seems not to have received the consideration it merits.—The trade names of the different sorts of paper designate the different sizes furnished from the mills. The smaller sheets of letter and note paper are prepared from the commercial sheets by the stationers. The smallest sheets furnished by the mills, termed pot paper, measure 12½ by 15 inches; foolscap, the next size, 18½ by 17; post, 15½ by 18½; copy, 16 by 20; large post, 16½ by 20½; medium post, 18 by 23; sheet and third foolscap, 18½ by 23; sheet and half foolscap, 18½ by 24½; double foolscap, 17 by 27; double pot, 25 by 30; double post, 19 by 30½; double crown, 20 by 30; double medium, 24 by 38; demy, 15½ by 20; ditto printing, 17½ by 22½; medium, 17½ by 22; ditto printing, 18½ by 23; royal, 19 by 24; ditto printing, 20 by 25; superroyal, 19 by 27; ditto printing, 21 by 27; imperial, 22 by 30; elephant, 28 by 28; atlas, 26 by 34; columbier, 23½ by 34½; double elephant, 26½ by 40; antiquarian, 31 by 53.—Beside the uses of paper already referred to, it is extensively applied to the production of pasteboard, paper boxes, paper hangings, sheathing for vessels, the outside covers of books, &c.

PAPER HANGINGS. See WALL PAPER.

PAPHLAGONIA, in ancient geography, a country in the N. of Asia Minor. According to the legendary account, the name was derived from Paphlagon, the son of Phineus. It was bounded N. by the Euxine sea; E. by Pontus, from which it was separated by the river Halys (the modern Kizil Irmak); S. by Galatia, separated by the Olgassys (now Uğaz) mountains; and W. by Bithynia, separated by the river Parthenius (now the Bartan-sn). The boundaries however varied at different periods. The

chief city was Sinope, situated on the coast and founded by a Greek colony. Beside this, there were Cytorus and Amastris on the Euxine, and Pompeiopolis and Gangra in the interior. With the exception of the Haly and Parthenius, and the Amnias (Kara-su), a tributary of the Haly, there are no rivers of importance. The Olgassys mountains in the centre, an extension of the chain running from Armenia to the Hellespont, send up to the northern part of the country numerous branches. Generally the surface is mountainous and rugged, but more especially in the southern portion, the northern containing many wide and fertile valleys, not inferior to the rest of Asia Minor in productiveness. Paphlagonia was celebrated for its horses, being spoken of on this account as early as the days of Homer. It also produced mules and antelopes, and in some parts sheep breeding was a common business, while the vast forests in the south afforded an ample supply of timber. A kind of red ochre was also obtained from a mountain called Sandaracurgium in the neighborhood of Pompeiopolis. The Paphlagonians appear to have been a Syrian race, and are spoken of as a rude and superstitious people. The chase was a favorite pursuit in peace, and their cavalry was celebrated in war. According to Herodotus (vii. 72), their armor consisted of a plaited helmet, small shields, and spears, javelins, and daggers.—Paphlagonia was originally governed by native princes, but was made a part of the Lydian dominions by Croesus; and after the conquest of the Lydian kingdom by Cyrus, it formed a portion of the third satrapy of the Persian empire. Yet various satraps made themselves independent kings of that country. After the death of Alexander, Paphlagonia fell into the hands of Eumenes, but after his fall was again independent until it became a portion of the dominions of Mithridates, king of Pontus. When the Romans had conquered that monarch, they united the coast districts with Bithynia, and subsequently embraced all of the country under their rule. In this condition it constituted a portion of the province of Galatia, and so remained until the time of Constantine, when it was erected into a separate province. Paphlagonia is now a part of the Turkish empire, and is included in the eyalet of Kastamuni.

PAPHOS, the name of two ancient towns, situated in the S. W. part of Cyprus, one of which was called Old Paphos, the other New Paphos, the former being the one denoted usually by the poets, the latter the one denoted by the prose writers; but as the same term was applied to both indiscriminately, much confusion has been the consequence. Old Paphos, the seat of the worship of Venus, and the goddess here, according to fable, she landed having risen out of the sea, was situated some distance from the shore, and owes its legendary name to Cinyras, the father of Adonis, whose peculiar seat of the goddess; here the temple was early established, the

grove and temple of Venus being mentioned in the Odyssey. The huge foundations of the latter are still visible. New Paphos, the modern Baffa, was situated between 7 and 8 m. N. W. of the old city, and was founded, according to the legend, by Agapenor, chief of the Arcadians at the siege of Troy, who was driven by the storm which separated the Greeks into its harbor. It was also remarkable for the worship paid to Venus, although it never rivalled in this respect the ancient city. It was here that St. Paul struck Elymas the sorcerer with blindness, and from the account in Acts the town would appear to have been the residence of the Roman governor.

PAPIAS, an early Christian writer, bishop of Hierapolis in Phrygia. Irenæus calls him a "hearer of John and a companion of Polycarp;" and it has been disputed whether the John referred to was the evangelist or the elder, who belonged to the church at Ephesus. He wrote a work in 5 books, entitled "Explication of the Speeches of the Lord," of which only a few fragments have been preserved. He was a millenarian in belief, and entertained the idea that there will be for 1,000 years after the resurrection from the dead a bodily reign of Christ on earth; and from him millenarians were sometimes called Papianists. According to the Alexandrian chronicle, he suffered martyrdom in Pergamus in A. D. 163, and Feb. 22 has been set apart by the Roman Catholic church for his commemoration. The best collection of the fragments of his writings is to be found in the *Reliquia Sacra* of Routh (8vo., Oxford, 1814). According to Eusebius, he was a man "of small understanding," as appeared from his works.

PAPIER MACHÉ, the pulp of paper mixed with glue or gum arabic, moulded and dried, or paper pasted in sheets upon models. The cheaper articles of papier maché are made of white or brown paper mashed in water and pressed in oiled moulds. The better articles are produced by pasting or glueing together sheets of paper, which, when a proper degree of thickness is attained, are powerfully pressed and dried. While moist the preparation may be moulded into any required form, and when dry it may be planed and rasped to shape. Several coats of varnish are next applied, and the inequalities are rubbed down with pumice stone. It is ornamented with gold, bronze powder, or colors, when a varnish of shell lac is applied, dried at a temperature of 280°, and a brilliant surface is obtained by polishing with rotten stone and oil, and by hand rubbing. For architectural ornaments, the sheets of paper prepared in layers with glue are pressed into metal moulds of the required form. When removed, a composition of paper pulp mixed with rosin and glue is put into the moulds, and the paper impressions being again inserted, the composition adheres to them permanently. *Carton-pierre* ornaments are similarly prepared, whitening being used in place of rosin, and are lighter and more durable than plaster of Paris. Pa-

pier maché is rendered to a great extent water-proof by mixing with the pulp a preparation of sulphate of iron and glue, and nearly fire-proof by adding to this borax and phosphate of soda. A "Treatise on the Decorative Use of Papier Maché" was published by Bielefeld (London, 1840).

PAPIN, DENIS, a French physicist and machinist, born in Blois in 1647, died in Germany about 1710. He received the degree of M.D. at Paris, and practised medicine there for some time; but having turned his attention to mechanics, he became the assistant of Huyghens, who had been attracted to France by the liberality of Louis XIV. He visited England in 1680, helped Boyle in several of his experiments, and was elected a fellow of the royal society. It was probably during his stay there that he prepared his *Dissertation sur la manière d'amollir les os, et de faire cuire toutes sortes de viandes en fort peu de temps et à peu de frais, avec la description de la machine* (Paris, 1682). In this work he explained his *digesteur* or *marmite*, a contrivance for softening bones, with which until lately his name has been chiefly associated; but recent investigations have shown that Papin has a better claim to celebrity as a forerunner of Watt and Fulton. Having removed to Germany on account of the persecution to which he was exposed in France as a Protestant, he was appointed in 1687 professor of mathematics in the university of Marburg, and there devoted his leisure to researches upon the use of steam. As early as 1690 he published the results of his labors in the *Acta Eruditorum* of Leipzig, proposing steam as a universal motive power, and describing a steam engine and even a rude paddle steamer. It appears from documents discovered by Prof. Kuhlmann in 1852 in the public library at Hanover, that in 1707 he had a vessel built in conformity with his invention, and tried it on the Fulda. His last published work was a Latin "Essay upon a new System for raising Water by the Action of Fire" (Frankfort, 1707).

PAPINEAU, LOUIS JOSEPH, a Canadian political leader, born near Montreal in 1787. His father, who was a notary public and held a seat in the first legislative assembly of Lower Canada after the establishment of the constitution of 1791, had him educated at Quebec with great care. He studied law and was admitted to the bar, but never practised. At the age of 23 he entered the Canadian parliament, succeeded his father in 1814 as one of the deputies of Montreal, and in 1815 was elected to the speakership of the house. He had already taken the lead of the radical party, and in order to neutralize his growing influence, Lord Dalhousie, when governor-general of Canada, appointed him one of the executive council; but he never appeared at any of its sittings, and continued his opposition to the government. In 1823, when the English party aimed at the union of the two provinces of Canada, Papineau, in conjunction with Neil-

son, was sent on a mission to London to remonstrate against that measure. In 1827 he was reelected to the house and rechosen speaker. Rather than sanction this choice, Lord Dalhousie adjourned the parliament, and it was not until 1828, when Sir James Kempt had succeeded to the governorship, that Papineau could take his seat. He now assumed an attitude of defiance toward the imperial government, which, however distasteful to some of his former adherents, was upheld by a majority of the people in Lower Canada. He prepared a list of the demands and grievances of his countrymen, which was introduced to the house in 1834 by M. Bédard, and known afterward as the 92 resolutions. He supported them energetically in the house, and at the close of the session went through the country urging a constitutional resistance to the imperial government, and recommending commercial non-intercourse with England as a means of bringing her to terms. He advised the colonists not to vote subsidies for more than 6 months, and this measure was carried out in the session of 1836; but the new governor, Lord Gosford, vetoed it, and decided upon administering the province without the assistance of the colonial parliament. This brought matters to a crisis. While the other provinces were conciliated by concessions and favors, Lower Canada was threatened with harsh measures; and this was seized upon by Papineau as a favorable opportunity to give a new impulse to agitation. He spoke with great effect in many of the parishes, and in several of them the governor was burned in effigy. The sudden prorogation of the colonial parliament added fuel to the fire, and the liberal party took up arms. This however Papineau did not approve, and in a great popular meeting, Oct. 23, 1837, he tried to bring his party to more sober resolutions, insisting that constitutional and peaceful resistance would alone be of avail to Canada. His advice was not heeded, and the final result of the meeting was a flaming "Appeal to the People." Thus reluctantly carried far beyond his anticipations, he remained among the rebels, although taking no active share in their military operations. A warrant for his arrest had been issued on a charge of high treason. After the engagements of St. Denis, St. Charles, and St. Eustache, in November and December, 1837, had demonstrated the futility of armed resistance, he took refuge in the United States, and afterward repaired to France, where he lived for several years, engaged in literary pursuits. After the passing of the bill for the union of the two Canadas in 1840, a general amnesty for political offences was granted by the home government, and he was allowed to return to his native country. His popularity was still strong enough to secure his election to the Canadian parliament; but he has since taken no prominent part in political affairs.

PAPINIANUS, EMILIUS, a Roman born about A. D. 170, put to death

He succeeded Septimius Severus as *advocatus flecti*, and, when his predecessor in that office became emperor, was appointed by him *libellorum magister*, and subsequently *praefectus praetorio*. It is probable that he accompanied Severus in his expedition to Britain, and the emperor on his deathbed is said to have commended his sons to his care. But in the second year of the reign of Caracalla, he was beheaded by order and in the presence of that tyrant. Papinian was one of the most eminent of the Roman jurists. Among his scholars were Ulpian, Paulus, Pomponius, Africanus, Florentinus, Modestinus, and others; and in the Digests are 595 extracts from his works. So high an opinion was entertained of his merits, that Oujas, the great French interpreter of civil law, declared that Papinian was the first of all lawyers who have been or are to be, that no one ever surpassed him in legal knowledge, and that no one will ever equal him.

PAPIRIUS, JUVENUS, a Roman jurist, who lived in the time of the Antonines, and compiled 20 books of constitutions. In the Digest there are 16 fragments from the first 8 books of this work. The constitutions are all rescripts of the Antonines, either of Marcus alone, or of Marcus and Verus jointly. Nothing is known of the collector save that he must have lived in the time specified, as the Antonines are named without the epithet Divus.

PAPIRIUS, SEXRUS, or PUBLIUS, the supposed collector of the old *Leges Curiatae*, or *Leges Regiae*, which were enacted at Rome during the reign of the kings. He is said to have been pontifex maximus, and to have lived under Tarquinius Superbus. The collection is mentioned under the name of *Jus Civile Papirianum*, and sometimes *Lex Papiria*, not because he contributed any thing, but because he arranged the laws in their order. Although much has been written in regard to this compilation, nothing certain is known. The few and doubtful fragments still extant are contained in Hoffmann, *Historia Juris Romano-Justinianei*, vol. ii. p. 1 (Leipsic, 1726).

PAPPENHEIM, GOTTFRIED HEINRICH VON, count, an imperial general in the 80 years' war, born May 29, 1594, killed at the battle of Lützen, Nov. 16, 1632. Descended from a noble and ancient family, he received a liberal education at Altdorf and Tübingen, and travelled over various countries of Europe. The military spirit of the times and his fiery zeal for the Roman Catholic faith led him soon to adopt the profession of arms, and he became a captain of cavalry in the regiment of his stepfather, the count of Herberstorff. At Lintz he joined the imperial army, and soon became lieutenant. At the battle of Prague, in 1620, he repulsed the Swedes, and was left for dead on the field, but recovered by his own men returned to the ranks of the enemy. In 1623 he was appointed him commander of a regiment, which became celebrated as the Pappenheimers. He

fought in Lombardy until 1625, when he was recalled to put down an insurrection of Protestant peasants in Upper Austria, who had resorted to arms to defend their faith. This rebellion, in which 40,000 peasants perished, he crushed in the space of a month; the history of it he himself wrote. Afterward he assisted Tilly in his campaign in northern Germany against Christian IV. of Denmark, and bore a leading part in the storming of Magdeburg (May, 1631). In the sack of this city his troops acted with the most terrible ferocity. In the defeat which his commander suffered at Leipa, Pappenheim received 7 wounds, and owed his life to a peasant. After the death of Tilly he joined Wallenstein, and in the battle of Lützen received a mortal wound; but hearing that Gustavus Adolphus had also fallen, he exclaimed: "Let the duke of Friedland (Wallenstein) know that I am mortally wounded; but I depart with joy, as I know that the implacable enemy of my faith has fallen with me on the same day." Pappenheim was especially distinguished for his daring and his fiery courage; but these qualities, which made him invaluable in a subordinate position, rendered him unfit for holding responsible commands.

PAPPUS, ALEXANDRINUS, a Greek geometer, who flourished, according to Suidas, in the latter part of the 4th century of our era; by some modern critics he has been placed in the latter half of the 2d century. Nothing is known of his personal history. He wrote several works, all of which have perished except the "Mathematical Collections," of which the last 6 out of 8 books are now extant. The first 3 it has been conjectured were taken up with the science of arithmetic; the 8d treats of linear and solid geometrical problems; the 4th of various propositions in pure geometry; the 5th of isoperimetrical figures; the 6th of the geometry of the sphere; the 7th of ancient analysis; and the 8th of mechanics. The lost works of Pappus are a "Commentary upon Ptolemy's Almagest," a "Universal Chorography," a "Description of the Rivers of Libya," and a treatise on the interpretation of dreams. There is no edition of the Greek text of the "Mathematical Collections," but two have been printed of the Latin version by Commandine (Pissauri, 1588 and 1602); a portion of the Greek text of the 2d book (wanting in Commandine's MS.) was printed by Dr. Wallis (London, 1688).

PAPUA. See NEW GUINEA.

PAPYRUS, a genus of plants belonging to the natural order *cyperaceae*, or sedge family—plants that frequent marshy places, and some of which are aquatic. The common bulrush, the pith of which is used by the poorer classes of England as a substitute for candle wicks, and the troublesome nut grass of the southern states, are familiar examples of this order. The papyrus plant, which was used by the ancient Egyptians for making their paper, is the *cyperus papyrus*, or *papyrus antiquorum* of some botanists. It grows on the marshy

banks of rivers in Abyssinia, Syria, and Sicily, and formerly abounded on the banks of the Nile; but it is questionable whether the plant now exists in Egypt. According to Sir Gardner Wilkinson ("Ancient Egyptians," vol. ii. pp. 97 and 100), it would seem to have disappeared there entirely; and, as he states, the remarkable prophecy of Isaiah (xix. 7) has come to pass: "The paper reeds by the brooks, by the mouth of the brooks, . . . shall wither, be driven away, and be no more." Its names however are perpetuated, one in the Bible or Book, so called from *byblus*, and the other, *papyrus*, in paper. The papyrus plant has a triangular smooth stem, from 5 to 25 feet high, bearing long grassy leaves springing from near the ground. The flowers form small flattened spikes, of 6 to 8 flowers each, which are clustered in great numbers, 300 to 400, in a compound head, 15 to 20 inches long, supported at its base by a many-leaved involucre. The cultivation of the plant received great attention in Egypt, where it was in ancient times highly valued, not merely for the manufacture of paper, but also as a medicine, being applied to the cure of fistulas and ulcers. It was also made into torches and candles, boats, sails, ropes, mats, garments, coverlets, shoes for the priests, &c.; and the roots, which grow as large as a man's arm, were used as fuel, and for making cups and other utensils. The head with its grass-like filaments was used to crown the statues of the gods and adorn the temples in Egypt. Pliny, who gives the chief part of this account, also states that the plant was used as food, being chewed raw, boiled, or roasted, and the sweet juice only being swallowed. The method of preparing the paper, according to the same authority, consisted in dividing the stem (probably the inner cuticle) by means of a kind of needle into thin plates or laminae, each as large as the plant would admit. These were placed upon a table, which was continually moistened with Nile water, to which Pliny attributed a peculiar alimy or adhesive quality, that specially adapted it for this use, a virtue more probably however derived from the plant itself. A layer of the papyrus being spread over the table the whole length of the slips, it was overlaid by another placed transversely, and these were afterward subjected to pressure. The sheets thus formed were then hung in the sun to dry, and were afterward joined together. A single stem sometimes produced 20 slips. The sheet when made of the desired length was rolled on a wooden roller, the ends of which projecting beyond the papyrus were carefully finished and ornamented with balls. At one time the use of the plants was monopolized by the government, and little could be used for other purposes than for paper, and on account of its scarcity even then only for the most important documents. Paper of papyrus was largely manufactured in Alexandria during several centuries of the Christian era, and was an important article in the com-

merce of the countries of the Mediterranean. The time of its final disappearance is unknown; but it was gradually going out of use, and paper from cotton and linen taking its place, in the 11th and 12th centuries. In the "American Journal of Science," vol. xxvii. pp. 81, 82, is a description of the papyrus plant as seen by the writer in 1884 on the banks of a small stream near Syracuse in Sicily. For the gratification of the curious, a Syracusan gentleman, Mr. Politi, at that time made and disposed of specimens of papyrus paper, using the pith of the plant; and the writer supposes this is the only portion that could be applied to this use. The outer integument resembles very much that of Indian corn.—When papyrus was first used for paper is unknown. Pliny says, but evidently very incorrectly, after the time of Alexander the Great. It was common in the time of Oheops, the builder of the great pyramid, many centuries before Alexander conquered Egypt. Its use no doubt became more general out of Egypt after the conquest. The material in modern times first came into notice in Europe when the history and antiquities of Egypt were developed by the French expedition. Papyrus rolls have since that time been collected by numerous travellers in Egypt. They were also brought to light among the ruins of Herculaneum. These were Greek manuscripts, unfortunately so injured as to be almost entirely illegible. They were of various textures and colors, and for the most part the sheets were matted together, so that only by the utmost care, patience, and ingenuity, could they be opened and deciphered. Even when the labor was attended with success, the importance of the documents was far from repaying the trouble. Some of the Egyptian papyrus manuscripts are written in Greek, and among these was found a valuable fragment of Homer. The funereal papyri, in hieroglyphic and other characters, seem to have been regarded by the Egyptians as a sort of passport after death to another world, and in the mummy cases they are found deposited about the persons of the occupants. These, though numerous, seem all to be copies with some variations from one original. The historical Egyptian papyri have thrown much light upon the manners and customs of the people, and have elucidated many points of Egyptian chronology and history. The papyri relating to judicial and civil affairs, though less interesting in most of their details, afford some curious information concerning the domestic life of the Egyptians. The most remarkable modern discovery of them has been the recent finding by M. Mariette of 150 papyri in the Serapeum at Memphis, of the greatest value for the civil and religious history of lower Egypt.—The papyrus is alluded to by many ancient writers, as Dioscorides and ophrastus. Under the name of *βυσσος* it is also treated by Herodotus, & Lucan. It is probably the rush.

Job, viii. 11; and it is supposed to have been the material of the "ark of bulrushes daubed with slime and pitch" in which Moses was found.

PARA, a Turkish coin of copper, silver, or mixed metals, very small and light. It is the fortieth part of a piaster, which varies greatly in value owing to the debased and complicated state of the Turkish coinage, but may be rated at about 4 cents of U. S. money; the para will therefore be worth 1 mill.

PARA, or **GRÃO PARA**, a province of Brazil, bounded N. by Guiana and the Atlantic ocean, E. by the provinces of Maranhão and Goyaz, S. by Matto Grosso, and W. by Alto Amazonas; extreme length 1,800 m., breadth 950 m.; area, 582,000 sq. m.; pop. in 1856, 207,400. The Amazon flows through Para in an easterly direction, and receives several tributaries of great size; the most important are the Tocantins, Chingua, Tapajós, and Madeira, the last of which forms the W. boundary line of the province for more than 500 m. The country rises gradually from both sides of the Amazon, and becomes mountainous on the frontier next Guiana, but in the opposite direction it does not reach any great elevation. The general features of the province may be described as immense plains intersected by great rivers. The tracts lying between the rivers are generally covered with primeval forests; but in places there are vast alluvial plains covered with rich verdure. The climate is warm, but not unhealthy. Gold, quicksilver, iron, diamonds, copper, coal, and salt are all found, but hitherto they have been much neglected. Much of the timber is of excellent quality; and some of the shrubs and plants which grow spontaneously are very valuable. But little of the surface has been brought under cultivation, and the principal crops raised are mandioc, rice, millet, coffee, cotton, and sugar cane.—The capital, **PARA**, or **BELEM**, is situated on the river Guama, which flows into the estuary of Para, about 70 m. from the Atlantic, in lat. $1^{\circ} 34' S.$, long. $48^{\circ} 50' W.$; pop. 28,000, about $\frac{1}{4}$ of whom are slaves. The streets are well laid out and paved. The houses are not generally high, but they are substantially and some of them elegantly built. There are a handsome cathedral and several churches, a governor's palace, a college, schools, hospitals, a botanic garden, a theatre, and a law court. The anchorage is safe and roomy, and, with the exception of two shoals at the entrance of the river, is easy of access. The approach to the town is commanded by a small

* The principal exports consist of cocoa, rubber, rice, nuts, and hides. In 1856, 1,950,048 lbs. of India rubber were exported. The value of the exports during the year 1856 was \$1,950,048, 42 per cent. of which was sent to the United States. The imports for the same year were valued at \$1,400,000, and consisted of manufactures, sugar, &c.

—applied to the Amazon, and applied to the arm of

that river which is separated from the mouth of the Amazon proper by Navajo or Joannes island. It is about 200 m. long, and the breadth varies from 40 m. at its mouth to 12 m. at its head, where it receives the river Anapa. The Tocantins is by far the largest and most important river which flows into it. At spring tides the bore rushes in with great force in a wave 15 feet high.

PARABLE (Gr. *παραβολή*, a comparison), a narration in which something is implied bearing a similitude to what is told. In the Bible the word is sometimes used as synonymous with a comparison, proverb, or sententious manner of speaking. The prophets of the Old Testament frequently spoke in parables. It was by a parable that Nathan reproached David, and Jesus Christ generally taught in the same manner.

PARABOLA, one of the conic sections, a curve formed by the intersection of a plane with a right cone having a circular base, the plane being parallel to one of the sides of the cone. The axis is the line drawn from the vertex dividing the figure into 2 equal and symmetrical parts; as the curve does not return upon itself, this line is infinite. This is the curve astronomers employ to represent the paths of comets, though these bodies probably move not in a parabola, but in a very eccentric ellipse.

PARACELSUS (**PHILIPPUS AUREOLUS THEOPHRASTUS BOMBASTUS VON HOHENHEIM**), a Swiss alchemist and empiric, born at Einsiedeln near Zürich in 1493, died in Salzburg, Sept. 23, 1541. He was the son of a physician, and received an irregular education, the defects of which he managed to conceal or supply by his remarkable self-possession and assurance and ceaseless curiosity. Having made himself master of the arts of conjuring, juggling, and alchemy, he travelled on foot through the principal cities of Europe, picking up scraps of knowledge and acquiring the rudiments of chemistry and medicine. He visited Constantinople in the suite of a Tartar prince to learn from a Greek the secret of the elixir of Trismegistus, and, having become acquainted with some remedies not in common use among the faculty, returned to Switzerland, where he performed several remarkable cures. On the recommendation of Ecolampadius, he was appointed professor of physic and surgery in the university of Basel in 1526. He proclaimed himself the sole monarch of physic, publicly burned the works of Galen and Avicenna, and professed to know the art of prolonging life and curing all diseases, and to hold more learning in the hairs of his beard than was possessed by all the universities and medical writers united. To the four elements of Aristotle he opposed the three compound principles of salt, sulphur, and mercury. The soul, according to him, was united to the body by an animal fluid. Man was an image of the Trinity, his intellect representing God, his body the world, and the fluid the stars. He recognized a mysterious

harmony between the body and the earth and salt, between the soul and water and mercury, and between the intellect and the air and sulphur. His lectures were delivered, not as was usual in Latin, but in the vulgar tongue, and attracted at first very large audiences. Erasmus consulted him for the stone, and the correspondence between the quack and the philosopher has been preserved. In his personal habits as well as his language, Paracelsus affected oddity. He slept in his clothes. He spent his nights carousing in low taverns. He rarely lectured that he was not drunk; he was drunk when he visited his patients, and drunk when he wrote his books. After the first year his lectures were deserted. At last, about the end of 1527, he was compelled to leave Basel on account of having abused a magistrate, and after wandering through Germany for several years obtained a temporary success in Moravia. The death of some of his most illustrious patients soon compromised him here, and he next visited successively Vienna, Villach, Mindelheim, and Salzburg, where he closed his life in abject poverty. He published a few works, and left in manuscript a number of others, which were printed after his death. There are several collected editions of his writings, one of the latest of which is in Latin in 8 vols. fol. (Geneva, 1658). With all his absurdities, he taught some true principles with regard to the uses of opium, mercury, sulphur, antimony, and arsenic, and was the first to introduce chemical remedies into the pharmacopœia.

PARACHUTE. See **BALLOON**.

PARADISE (Sans. *pardesaka*; Heb. *pardes*; Armenian, *pardes*; Arab. *firdaus*; Gr. *παράδεισος*), literally, a garden or pleasure ground planted with trees and flowers, whence the term is used metaphorically to express the abstract idea of perfect felicity and heavenly blessedness. In the Septuagint it is employed to express the Hebrew "garden of Eden." (See **EDEN**.) Another metaphorical use of the word is to express the happiness of the righteous in a future state, an application adopted by the later Jews, and the general idea of which is to be found in the mythologies of various races. The mediæval rabbinical literature contains fanciful descriptions of an earthly and a heavenly paradise, the latter, which excels the former "as much as darkness does light," being reserved for the final abode of the souls of the blessed. Each of them contains seven divisions or chambers, and each of these chambers extends 120,000 miles on every side. A column ascends from the terrestrial to the celestial paradise for the convenience of the souls of the blessed who are entitled to ascend thither, and a wall of partition separates the whole from hell. The location of the terrestrial paradise is somewhere under the equator. The celestial paradise is generally regarded as identical with heaven, or the place of future bliss according to the Christian dispensation; but biblical critics have differed as

to the signification to be given to the term in Luke xxiii. 43, where Christ says to the penitent thief: "To-day shalt thou be with me in paradise;" some considering the existence of a distinct abode for the reception of the blessed previous to the last judgment to be indicated, while others have found a stumbling block in the statement elsewhere made in Scripture that between his death and resurrection the Saviour descended into hell. The paradise of the Mohammedans, termed in the Koran *Gannah*, or the happy gardens, is a place of infinite sensual delights conceived with all the warmth of oriental fancy, where devout followers of the prophet are received after death.

PARADISE, BIRD OF. See **BIRD OF PARADISE**.

PARADOX, MECHANICAL. See **GYROSCOPE**, vol. viii. p. 618.

PARAFFINE (Lat. *parum affinis*, having little affinity for other bodies), one of the hydrocarbons discovered in 1880 by Reichenbach as products of the destructive distillation of organic bodies. He found it first in wood tar, and also separated it in the treatment of flesh and of the coal oils. Christison of Edinburgh, not knowing of Reichenbach's discovery, found it in 1881 in Rangoon petroleum, and named it petrolin. In its appearance and properties it resembles spermaceti and white wax. It is of crystalline texture, solid at ordinary temperatures, and melting when pure at 130° F.; if at 110°, as commonly represented, it is not freed from the oil associated with it. On melting it forms a transparent, colorless, oleaginous fluid, which by increase of temperature first boils, and then evaporates in white vapors, leaving no residue, unless the heat is insufficient to decompose it. In the fluid condition it is absorbed by a wick, and burns like spermaceti. At ordinary temperatures it does not produce spots, as grease does, upon other substances. Its density is 0.87. Paraffine is remarkable for its indisposition to unite with other bodies, and for its power of resisting their action. The acids and alkalies, the latter even in a caustic state, have no effect upon it, nor does it mix when melted with sulphur, phosphorus, &c. With substances, however, which it most nearly resembles, as spermaceti, wax, stearine, and others; it mixes freely; and it is dissolved by many of the vegetable oils and by ether. Alcohol when cold dissolves very little of it, and this is precipitated by adding water; boiling absolute alcohol takes up about 8.45 per cent. of it. Its natural solvents are the hydrocarbon oils which are obtained with it by the distillation of bituminous substances, or which form with the paraffine the natural rock oil or petroleum. For the method of obtaining it, see **PETROLEUM**. It is obtained in larger proportion from the oils of the Boghead canal than from the heavier western oils, natural and extracted from the coals; and it is supposed that some portions of these oils

are isomeric with paraffine, but they do not assume its solid consistence.—Paraffine was produced by Selligie in France, and made into candles, which, with other products of the distillation of bituminous substances, were exhibited in the Parisian industrial exhibition of 1889. "The purified mineral wax," as it was called, "was beautifully white, but the candles made of it had a soiled appearance." This appears to have been owing to its tendency to split as it cools, and thus form cracks that radiate from the wick. A mottled or clouded appearance is thus produced, which for some time it was difficult to prevent. Several methods of moulding, however, have been devised by which this difficulty is avoided. By one process, described in the *Technologist* of 1859, and adopted in the United States, the mould is made in two parts, one for the body of the candle, and the other a short piece for the tip, which has a conical depression for forming the point of the candle. This piece fits in the other like a piston, so that when pushed in it forces the candle out of the other end. The moulds, being brought up to the temperature of boiling water, are filled and immediately plunged into water but little above the freezing point. After remaining about 5 minutes, in which time the paraffine becomes solid next the moulds, they are taken out and kept in a current of cold air for about 20 minutes. These candles are in no respect inferior to spermaceti. Their manufacture is now introduced into several of the mineral oil factories, and must, in view of the very rapid increase of these works in the United States, soon become of great importance. In Europe paraffine has been produced from peat (see *PEAT*), wood, and other combustible organic substances. But it will not probably be found profitable to extract it from other substances than the natural bitumens.

PARAGUAY, a name formerly denoting a large portion of South America, stretching from the sources of the river Paraguay in the N. to the straits of Magellan in the S., and from the Portuguese captaincy of St. Vincent and the shores of the Atlantic on the E. to the Andes on the W. It is now applied only to the republic of Paraguay, lying in the inland peninsula enclosed by the rivers Paraguay and Parana, between lat. 22° and 27° 40' S., and long. 54° and 58° 40' W.; length N. and S. 400 m., breadth from 170 to 210 m.; area about 75,000 sq. m. Its exact northern limit is still undetermined, Paraguay claiming to the N. as far as the Rio Blanco, and Brazil placing its boundary to the S. as far as the rivers Ipane and Jeju. Meanwhile, by the tacit consent of the nations, a generally recognized frontier has been established, and is formed by the Rio Corrientes, a tributary of the Rio Jeju, and the Yaguarey, a branch of the Rio Parana, flowing N. and E. by Brazil, S. by Paraguay, and W. by the unsettled region between the Great Chaco, to a portion of

which Paraguay lays claim. The republic is divided into 81 *partidos*, or districts, each having a government commissioner at its head. Of these, 56 are inhabited by whites or mestizos, 28, including 8 Jesuit *pueblos* or missions, by Indians, and 2 by mulattoes. The capital is Assumption or Asuncion, situated on the Paraguay, and having a population of somewhat over 12,000. There are 10 *villas* or towns, which may in a measure be considered as provincial centres. They are Villa Rica, 108 m. S. E. of Assumption, near the head waters of the Tebiquary; Curuguaty, 50 m. N. E. of the capital; San Pedro, on the Jeju; Rosario, near the mouth of a small stream called the Quaripoty; Carmen, in the S. near the Parana; Villa del Pilar (formerly Neembucu), Villa Franca, Oliva, Concepcion, and San Salvador, on the Paraguay. The population of these *villas* ranges from 1,000 to 4,000. The total population has been variously estimated, but the most probable computation places it at 600,000, of which scarcely 1,000 are slaves of African descent.—The Paraguay and Parana are a part of the great fluvial system of the river La Plata. The former, which is subject to regular periods of rise and fall, is navigable to a considerable distance beyond the northern confines of Paraguay, and along the line of the republic the depth of the channel is nowhere less than 12 feet at the most unfavorable seasons. The latter is more irregular in its changes, and appears to be easily navigable for river steamers about 200 m. above the point where it is joined by the Paraguay, its upper course being greatly interrupted by rapids and cataracts. The affluents of the Paraguay, on the eastern or Paraguayan side, are the Apa or Corrientes in the N., and then, proceeding S., the Aquidaban or Aquidabanigry, rising in the Sierra de Amambay and flowing N. E. and S. W.; the Ipane, the Jeju, the Salado, and the Tebiquary in the S. The last is the most important, taking its rise in the elevated plateaus of the E. and affording to vessels of light draft 80 leagues of navigation through a fertile and populous region. The chief Paraguayan tributaries of the Parana are the Amambay, the Ygatimi, and the Yaguarey. The lakes are few and insignificant. The largest is the Ypoa, 15 m. in length, surrounded by an extensive morass, and pouring its waters into the Tebiquary; the next in size is the Ypacarahy, a short distance N. E. of Assumption, about 12 m. in length by 8 in breadth, and discharging its waters, by means of the little river Salado, into the Paraguay. In the low lands numerous extensive *esteros* or marshy jungles exist, of which the estero of Neembucu in the extreme S. E., and that of Aguachy in the N., are the best known.—A range of mountains of moderate elevation enters Paraguay at the N., where it is styled the Sierra de Amambay, proceeds southward, and is known in its central and highest portions as the Sierra de Maracayn, and finally terminates near the southern frontier in the lofty hills of Caaguazu.

In lat. 24° it sends off a branch to the E., which, crossing the Parana, forms the cascade of Salto Grande. Between lat. 25° and 26° a lesser branch runs to the W. The average width of the range is about a degree, and it forms a watershed between the streams which flow on its eastern side into the Parana, and on its western into the Paraguay. Paraguay is to be regarded, to a certain extent, as a transition land between the uneven and mountainous region of Brazil and the vast country of the pampas. The surface is divided between the central and eastern mountains, the wooded, outcropping hills of the sierras, and the *campos queltrados* or undulating plains of the S. E. A line drawn from Assumption on the Paraguay to Encarnacion on the Parana would, with those rivers, form a delta enclosing these fertile plains. They are composed of a ferruginous sand and clay, with vast depressions filled with rich alluvial deposits of a modern date. In many parts their soil derives from the oxide of iron a peculiar tinge, which led the Jesuits to give it the name of "red earth." The *campos* are interrupted by *lamos*, curious hills of a hemispherical shape, covered with grass. Toward the N. they increase in size and are wooded. The entire geological structure of Paraguay belongs to the tertiary system.—The climate is tropical, but the heat is greatly modified by the peculiar character of the country and other influences. At Assumption the mean annual temperature is about 85°. Rains do not occur periodically as in the countries nearer the equator, nor are the seasons well defined as in more temperate regions. June, July, and August are the coldest months, but even then the mercury rarely falls to the freezing point. The hottest period is in December, January, and February. Hail storms and thunder storms are of very frequent occurrence, but earthquakes are almost unknown. The nights are serene and cool. The *virazon* is a refreshing and regular east wind. Another wind, coming from the north-east over the humid plains of the tropics, is hot and heavily charged with moisture; it depresses the spirits, is a frequent cause of disease, and affects both vegetable and animal life. The *pampero* is from the south-east; it comes dry and chill from the pampas, sometimes causing the mercury to fall 18° in a single hour, and its violence often spends itself in hurricanes and tempests, resulting in great destruction of property.—Little attention has been given to the mineral wealth of Paraguay. Gold and silver are said to have been found in small quantities, and an iron mine is profitably worked at Cerro San Miguel. A few saline plains in various parts yield nearly enough salt for home consumption. The vegetable products are of immense value and endless variety. The mountains and hills are covered with forests of trees whose woods, bark, gums, and fruit are used in many of the arts. The commonest genus appears to be the mimosa, but the cedars, palms, laurels, quassia, brignonia, and ilex

are widely spread. The *lapacho*, *quebracho*, *tatane*, and *urunday* almost rival the metals in hardness and durability; while the fine and firm fixture of the *morosimo*, *palo amarillo*, and *palo de rosa* peculiarly adapt them to the purposes of the cabinet maker. The fruits of the *arahan*, *nangapare*, *algaroba*, and *yayuma* are pleasant and nutritious. The caoutchouc or *seringar* yields the India rubber gum, and the *palo santo* produces the gum guaiacum. One species of cactus furnishes the food of the cochineal insect. From a parasite, the *guembe*, and from an aloe, the *curuguaty*, ropes and cables are manufactured, exceeding in strength those made of hemp. The varieties of the bamboo are numerous. The flora produces also many important medicinal drugs, as copaiba, rhubarb, sassafras, jalap, sarsaparilla, nux vomica, dragon's blood, and licorice, and many dye stuffs. But the most important vegetable production is the *yerba maté*, or Paraguay tea (*ilex Paraguensis*), which yields the favorite beverage of a large portion of South America. It grows from the vicinity of Rio Janeiro to the base of the Bolivian Andes, but nowhere in greater abundance than in Paraguay, where large quantities are consumed and exported. It is found wild in the extensive *yerbales*, as they are styled, on the hills of the interior, and is gathered and cured by government, or by contractors who have purchased the rights of certain *yerbales* from the president. The plant has the size and appearance of the orange tree, and its clusters of white flowers closely resemble those of our elder. Among the flowering plants, the parasitic orchids and the *mais del agua*, nearly the same as the *Victoria regia*, are the most remarkable. The cultivated plants are the sugar cane, tobacco, mandioca, rice, maize, cotton, indigo, and some of the cereals. The principal indigenous mammalia are the jaguar, cougar, wild boar, deer, ocelot, monkey, tatou, peccary, tapir, aguara, and ant-eater. The rivers and estuaries abound in alligators, capibaras or river hogs, cavies, and others. Bats are numerous. Boas and one or two very poisonous serpents occur, but the rattlesnake is less common than in Brazil. The ornithology of Paraguay comprises the vulture, which is not now so often seen as formerly, the buzzard, many species of parrots, the American ostrich, the toucan, the partridge, the *pato real* or wild duck, the *bigua bay*, the teal, and numerous songsters. A species of ant deposits nodules of wax upon the twigs of the *guayara blanca*, which are gathered and made into candles. The mosquitoes are a source of great annoyance, and the locusts sometimes devastate large districts. The favorite edible fish are the *pacu*, not unlike our turbot, *dorado*, and *palo-meta*.—There are no traces in Paraguay either of remote or present volcanic action. Meteoric stones are a phenomenon of not uncommon occurrence. The Salto Grande, or cataract of Guayra, on the Parana in lat. 24°, is the most striking natural curiosity. The river, which

general mountainous, and between the mountains there are extensive valleys, which for the most part have a dry sandy soil. Near the rivers there are tracts of good ground, where rice and sugar cane are raised; and on the slopes of the hills cotton, tobacco, and mandioc thrive well. The forests afford excellent timber, gums, resins, and other products. The chief exports are cotton, sugar, and timber. There are several schools in the province; and it sends 2 senators and 5 deputies to the imperial legislature.—The capital, PARAHIBA, is situated on the Parahiba river, about 16 m. from the sea, and 65 m. N. from Pernambuco; pop. 15,000. There are several public buildings and churches, a number of religious houses belonging to the Carmelites and other orders, a college, and 2 primary schools.

PARAHIBA DO SUL, a river of Brazil, which has its source in the E. part of the province of São Paulo, on the N. side of the Serra do Mar, enters the province of Rio de Janeiro, and after a tortuous course of more than 500 m. falls into the Atlantic at São João da Praya, in lat. $21^{\circ} 38' S$.

PARALLAX, the apparent displacement of a heavenly body arising from a change of the observer's position. The angle subtended at the body by the line joining the two stations is the measure of the parallax. As the positions of the heavenly bodies have reference in practical astronomy to the earth's centre, a correction for parallax is necessary in every observation, except when the body is in the zenith, where the parallax vanishes. It is greatest in the horizon, and is there termed horizontal parallax. Annual parallax is the variation of a star's place by being observed from opposite points of the earth's orbit. This is extremely minute, notwithstanding the great length of the base line, and is so difficult of determination that it long defied the endeavors of astronomers to detect it. (See ASTRONOMY.) The apparent absence of stellar parallax was considered by Tycho Brahe fatal to the Copernican doctrine of the earth's orbital motion. Galileo suggested a mode of investigating the problem by observations on two stars of different magnitudes situated close together. This mode has been successfully applied by modern observers. Hooke was the first to use the telescope in this investigation, but he failed. The aberration of light had not then been discovered, and the result he announced as parallax was probably due to this cause. The same is to be said of Flamsteed. The attempts of astronomers to determine parallax led to two signal discoveries, the aberration of light by Bradley (1725), and the systems of double stars by the Herschels (1781). The earliest approximate successful researches on this problem were made by the elder Struve, begun in 1835 and continued till 1840, though his conclusions were not received with entire confidence by astronomers. The first unequivocal success was achieved shortly afterward by Bessel at Königs-

berg on the star 61 Cygni, and by Henderson at the Cape of Good Hope on the star α Centauri.—The problem of the parallax of the fixed stars is precisely the same in kind as that of the distance of an inaccessible object upon the earth's surface. When an object is near, a small change in the point of view will displace the object sensibly. Even the two eyes do not see a near object in the same position; thus by looking at it first with one eye closed and then with the other closed, its place, as referred to an object behind it, is made to shift to and fro. This is called binocular or two-eyed parallax, and is the well known principle of the stereoscope.

PARALYSIS, or PALSEY (Gr. *παράλυσις*, relaxation), loss of the function of motion or sensation, from an interruption or destruction of the nervous influence necessary to those acts. This may occur either in the brain, the seat of sensation and volition, in the course of the nervous connection (spinal marrow and nerves) by which sensation and volition are conveyed to and from the brain, or, in some instances at all events, in the peripheral termination of the nerves. The nerves of special sense are sometimes affected with paralysis; thus we have arising from this cause amaurosis (blindness), cophosis (deafness), anosmia (loss of smell), and agustia (loss of taste). Anæsthesia, loss of the sense of touch or feeling, is rarely observed except as connected with loss of motion; and it is to this latter affection, attended with more or less anæsthesia, that the term paralysis is commonly applied.—Paralysis of motion is mainly of three kinds: hemiplegia, depending on apoplexy (see APOPLEXY) or softening of the brain; paraplegia, depending commonly on congestion, softening of, or hæmorrhage into the spinal marrow (see SPINAL MARROW, DISEASES OF); and partial paralysis, when from pressure at the root or in the course of a nerve, arising from a tumor, morbid growth, &c., from mechanical injury, or often from some unknown cause, the parts supplied by a particular nerve are paralyzed. The paralysis of the muscles of one side of the face, arising from an affection of the *portio dura* of the 7th pair, is a familiar example of this variety of paralysis. Again, certain mineral poisons, particularly the preparations of lead and arsenic, cause paralysis both of sensation and motion, and the paralysis in these cases is commonly attended by peculiar symptoms by which its nature can be recognized. It will thus be seen that paralysis is a symptom rather than a disease, and occurs in complaints differing widely in their seat and their causes. As diseases of the brain and spinal marrow produce by far the most numerous and most serious cases of paralysis, and as it is these cases that principally interest the physician, the reader is referred to the articles on those organs for the further elucidation of the subject.

PARAMARIBO, the capital of Dutch Guiana, on the river Surinam, about 5 m. from its

mouth, in lat. $5^{\circ} 49' N.$, long. $55^{\circ} 38' W.$; pop. 15,000, 9,000 of whom are blacks. It is intersected by 8 canals, and the streets generally lie at right angles to each other. It contains several churches, 2 synagogues, and some charitable institutions, and is the centre of the Dutch West India trade. Sugar, coffee, cotton, and indigo are the chief exports; and provisions and manufactured goods are imported.

PARAMATTA, a town of New South Wales, situated on a small river of the same name near the W. extremity of Port Jackson, in lat. $38^{\circ} 48' S.$, long. $151^{\circ} 1' E.$, 16 m. W. N. W. from Sydney; pop. about 5,000. The streets are wide and regularly laid out, but badly paved, and the main avenue is about a mile long. There are several churches and schools, an orphan asylum, a lunatic asylum, and a prison; but the town has lost a great deal of its importance since New South Wales ceased to be a penal colony. The observatory was removed to Sydney in 1858. Woollen cloths called "colonial tweed" and "Paramatta cloth" are manufactured, and salt is made in the vicinity. Paramatta is connected with Sydney by railway, and small steamers ply between them at short intervals throughout the day.

PARANA, a S. province of Brazil, bounded N. by São Paulo, E. by the Atlantic ocean, S. E. by Santa Catarina, S. by Rio Grande do Sul, and W. by Uruguay and Paraguay; extreme length 460 m., breadth 850 m.; area, 115,000 sq. m.; pop. in 1856, 72,400. It was set off about 1853 from the province of São Paulo, of which it formerly constituted the *comarca* of Curitiba. Curitiba is the capital, and Paranaguá the chief port. The sea coast is indented by several bays, and many small islands lie at short distances from the shore. A range of mountains runs in an E. N. E. and W. S. W. direction about 80 m. from the sea coast, and several offsets extend from it toward the interior of the country. The province is watered by numerous rivers, the most important being the Parana, which flows along the greater part of the W. frontier, and receives nearly the whole of the drainage of the province through its tributaries the Paranapanema, Iray, Piquere, Yunasan, and Uruguay. The climate is remarkably healthy. The soil is fertile, and the inhabitants are chiefly occupied in agricultural pursuits, and in rearing cattle and swine. Large quantities of *maté*, or Paraguay tea, are exported, but the general trade is inconsiderable. A European colony was established near the centre of the province between 1851 and 1855, upon part of an extensive tract of land which the prince de Joinville received as a marriage portion with Dona Francisca, sister of Dom Pedro II. It is called the Colonia Dona Francisca, and in 1857 the immigrants and their children numbered about 1,500, chiefly Swiss, with some French and Germans.

PARANA, a river of South America, which has its sources in the province of Minas Geraes, Brazil, about 100 m. N. W. from Rio de Ja-

neiro, near lat. $20^{\circ} 30' S.$ and long. $43^{\circ} 30' W.$, and, after receiving many tributaries, flows into the estuary called the Rio de la Plata by several mouths, between lat. $38^{\circ} 45'$ and $34^{\circ} 30' S.$, after a course of about 2,040 m. It flows at first in a W. direction for 500 m., till it is joined by the Parnahiba, when it turns S. S. W. to the boundary of Brazil and Paraguay, near which, about lat. $24^{\circ} 30' S.$, it forms the cataract called Salto de Sette Quedas, and then runs S. and for about 120 m. forms the dividing line between Brazil and Paraguay. It continues in a southerly direction for 60 m., and then turns S. W. and afterward W. till it is joined by the river Paraguay a little above Corrientes. Thence it pursues a S. course to Santa Fé, where it separates, forming several islands, and flows S. E. till it unites with the Uruguay to form the Rio de la Plata. Its principal tributaries are the Paraguay (which is larger and longer than the stream in which its name is lost), the Yunasan, Iray, Paranapanema, Pardo, Tiete, Parnahiba (which next after the Paraguay is the most important), and Mujiassu. It is navigable to Corrientes for vessels drawing $7\frac{1}{2}$ feet, and for smaller craft to Candelaria, 150 m. further, where rapids occur.

PARAPHERNALIA (Gr. *παρά, beside, and φερνῃ, dowry*), in law, all the personal apparel and ornaments of the wife, which she possesses, and which are suitable to her condition in life. The word was borrowed from the Roman law. The *dos*, or dowry, of a Roman wife was that portion which was contributed by her, or in her behalf, toward bearing the expense of the household (*ad sustinenda matrimonii onera*). That part of her property, over and above her *dos*, which she withheld, constituted her *bona paraphernalia* (*bona quæ præter dotem uxor habet*). This property generally remained in the hands of her father or tutor (guardian), and the husband had no rights over it, except those which were expressly given him by the wife. If she brought any chattels of her paraphernalia into her husband's house, he had the use of them; but, for the assurance of her title, the wife made an inventory of the chattels and the husband signed it. The paraphernal estate might consist of any kind and any amount of property. The husband had no interest in it, and the wife might dispose of it, or bring an action in respect of it, without his authority or consent. These, and the other rules of the Roman code upon the topic, remain without material modification in the modern civil law of Europe.—In the English law, paraphernalia acquired a meaning widely diverse from that which it bore in the Roman law. Yet in its earliest use it was no doubt applied with a regard to its etymology, and is therefore as correctly used in our own as in the civil law. Thus, the old authors Cowel and Blount define paraphernalia as "those goods which a wife brings to her husband, besides her dower and jointure, is all she has after her husband's death," thus allowed to the wife are, as

the personal apparel and ornaments which she possesses, and which are suitable to her rank and condition in life. It is essential that these things came to her from the husband, for articles given to the wife by any other, as by her father or other relation, or even by a stranger, are absolute gifts to her, and are secured to her separate use. But the paraphernalia are gifts *sub modo*. During his lifetime, the husband may dispose of all of them but her necessary apparel, and, with the same exception, they are subject after the husband's death to the claims of his creditors. Nothing however but insolvency, or complete alienation or sale by the husband, will defeat the wife's right of ownership. Pledge of the goods will not suffice. Her right cannot be defeated by the husband's will bequeathing the paraphernalia. If they were in her possession at the time of her husband's death, she will hold them against his executors or personal representatives.—Paraphernalia is quite an obsolete title in American law, the common law rules on the subject being generally superseded by the provisions of state statutes.

PARASANG (Gr. *παράσαγγος*), a measure of length among the ancient Persians, which appears to have varied considerably, being from 80 stadia (8½ m.), which is the measurement of Herodotus, to 60 stadia. According to Rawlinson, it was originally a measure of time (an hour), not of distance, and in passing from the one meaning to the other it came to mark a different length in different places according to the nature of the country traversed. The modern Persian *farsakh* varies from 3½ to 4 m.

PARASITE. See ENTOMOZOA, and EPIZOA.

PARCÆ (Gr. *Μοῖραι*), or **FATES**, in Grecian and Roman mythology, daughters of Erebus and Night or of Jupiter and Themis. They had control over the universe, and particularly human destinies, presided over all great events in the lives of men, executed the decrees of nature with inexorable decision, and punished criminals through their ministers the Furies, whose sisters they were sometimes said to be. In Homer *μοῖρα* is fate personified, and is almost invariably mentioned in the singular; but Hesiod describes 3 fates: Clotho or the spinner, who spun out the thread of human life; Lachesis, the disposer of destinies, who twirled the spindle while Clotho held the distaff; and Atropos the inevitable, who cut the thread when it had reached its proper length. They are sometimes regarded simply as the goddesses of the duration of human life, in which case they are but two in number, one presiding over birth and the other over death. They were depicted by the poets as hideous old women, cruel, and sometimes lame. They had many parts of Greece.

PARCHMENT (Lat. *pergamena*), the skins of other animals, so prepared in such a manner as to be fit for being written upon. It is known at a very early period, and its nature of it is no doubt

an eastern invention, which is said to have been improved if not originated by Eumenes II., king of Pergamus (who reigned 197–159 B. C.), whence its name. Herodotus states that the ancient Ionians wrote on skins many ages before that time. Wilkinson in his "Ancient Egyptians" says: "The use of parchment, or of prepared skins, for writing upon, was not however first suggested at Pergamus; it had been known ages before in Egypt; and records kept in the temple are mentioned in the time of the 18th dynasty, 1,800 years before Eumenes, written upon skins called *Thr* or *Takar*—a name which, as Mr. Birch thinks, resembles the Chaldee *Tzar*. Rolls of leather are also found in the tombs, buried with the deceased in lieu of papyrus, which are of a very early period, and were adopted in consequence of the high price of the papyrus paper." The early Arabs inscribed their poetry and compositions on the shoulder bones of sheep; and after their conquests in Asia and Africa these people so speedily profited by the inventions of the nations they subdued, that parchment was manufactured in Syria, Arabia, and Egypt, which in color and delicacy might vie with our modern paper. The ancients generally wrote only on one side of their parchment; but so valuable was it, that they not unfrequently erased the writing and used it a second time. Up to the present day, notwithstanding it has been superseded to a very great extent by the introduction of paper, no substitute for it has been found in a variety of purposes to which it is applied. The finer sorts of parchment called vellum, used for important writings, as deeds, wills, &c., are manufactured from the skins of calves, kids, and still-born lambs. The heavier parchment for drum heads is made from the skins of asses, older calves, wolves, and goats. The skins of most animals are suitable for parchment, but the better sorts being in demand for leather, the inferior kinds are chiefly taken for the former material. All these are similarly prepared. The skin, being freed from the hair, is placed in a lime pit for the purpose of cleansing it from fat. The pelt is then stretched upon a frame fixed against the wall of the building, formed of 4 wooden bars perforated with holes, in each of which is a peg or screw. A number of cords are tied firmly to the edges of the skin and passed through holes in the screws, which by being twisted bring the skin to the required tightness. Great care must be taken that the surface be perfectly free from wrinkles. The skinner then with a semicircular knife, called a half-moon knife, pares away all the fleshy excrescences from the one side, and turning the frame over scrapes off the dirt, slime, and moisture from the other. The surface is next ground by scattering sifted chalk or slaked lime on the flesh side, and rubbing it with fine pumice stone, the lime taking up still more of the moisture. The grain side is then rubbed with the pumice alone. The skin is dried gradually, and in the winter care must be

taken to secure it against frost. In summer it must be occasionally moistened to prevent its drying too suddenly. Whenever this is done, it requires immediate tightening. The woolly side of lambskin is used for removing the chalk and lime. Should any traces of grease be discovered, the skin is again soaked in a lime pit for 8 or 10 days, when it is again stretched and dried. This process being completed, it is cut all round, taken out of the machine, and fastened with cords upon a piece of calf skin which is extended on a frame, and reduced to about half its thickness by being pared with a sharp knife. This operation requires considerable skill and a steady hand. Such irregularities as remain are easily removed from the skin, which is laid upon a cushioned bench and then rubbed with pumice. Should any small holes appear in the parchment, they are neatly mended by paring down their edges, and pasting on small pieces with gum water. The green color is given to parchment by a solution made with 80 parts crystallized acetate of copper and 8 of bitartrate of potassa in 500 of distilled water, 4 parts of nitric acid being added when the mixture is cold. The parchment being moistened, this preparation is applied with a brush, and the polish is given by white of egg or mucilage of gum arabic.

PARDOE, JULIA, an English authoress, born in Beverley, Yorkshire, in 1812. She is the daughter of an officer in the British army, and early manifested a great fondness for literature, producing a volume of poems when she was only 13 years old. The first of her works which gave her any celebrity was "Traits and Traditions of Portugal" (2 vols. 8vo., 1838), which country she had visited for the benefit of her health. In 1835 she went to Constantinople, and upon her return published "The City of the Sultan" (3 vols. 8vo., 1836), and furnished the letter-press for "The Romance of the Harem" (8 vols. 8vo., 1839), and "The Beauties of the Bosphorus" (3 vols. 4to.). On returning from a trip to Hungary, she wrote a work upon the institutions of that country, entitled "The City of the Magyar" (3 vols. 8vo., 1840), which was followed by the novel of "The Hungarian Castle" (3 vols. 8vo.). Turning her attention to French history, she produced one of the best known of her works, "Louis the Fourteenth, and the Court of France in the Seventeenth Century" (3 vols. 8vo., 1847), and after a short interval the "Court and Reign of Francis I" (3 vols. 8vo.), and the "Life of Mary de Medicis" (3 vols. 8vo.). Among Miss Pardoe's numerous other works may be mentioned "The Confessions of a Pretty Woman," "The Rival Beauties," "Reginald Lyle," "The Jealous Wife," "Thousand and One Days" (1857), a collection of oriental tales, and "Pilgrimages in Paris" (1858). In 1859 she received from the crown a pension of £100.

PARDON, in its proper sense, the act of grace by which the sovereign declares that the guilty shall be regarded as innocent. In hu-

man political societies, this effect is accomplished, not by absolving the moral guilt of the criminal, but by removing or withholding those penal consequences which the law attaches to crime, and which indeed among men alone distinguish the guilty from the innocent. Complete pardon therefore involves remission of all the penalties which the law has inflicted on the offender; not the fine or imprisonment only, or whatever else may have been the physical form of punishment, but also all the infamy and all the incapacities which infamy imposes. Full pardon completely restores the civil status of the criminal. The remission of part of the penalties, when that is an act of clemency purely, may be called a partial pardon. From pardon, whether complete or partial, in this its proper sense, is to be distinguished that mere remission of penalties which, though popularly and perhaps conveniently called pardon, is nevertheless not so, because it is an act of justice and not of grace. A slight examination of the elements of pardon will show that this use of the word is incorrect, and that an observance of the distinction is material. Before proceeding to this, it will be well to repeat here the definition of pardon which was given by Chief Justice Marshall. It may not be altogether exact, but it is often quoted in our law books, and expresses the usual acceptation of the word. "A pardon," said Marshall, "is an act of grace, which, proceeding from the power intrusted with the execution of the laws, exempts the individual on whom it is bestowed from the punishment which the law inflicts for a crime which he has committed." A pardon is then an act not of justice, but of grace. Pardon necessarily implies punishment; and punishment, in all well ordered states at least, supposes guilt, ascertained in the due course of law, and justly visited with a penalty. For, as in the state it must be the theory, to say the least, that the courts have the monopoly of doing justice—that is, if the impartial and exact application of laws, which are intended and supposed to dispense justice, does in fact accomplish that end—so, theoretically, it must be assumed, and generally it will be rightly assumed, that he is guilty whom the courts declare to be so, and that the penalty inflicted is justly inflicted. If the punishment of such a one be but an act of justice, the remission of it, or a pardon, must be an act of clemency or grace. But it is the chief end of punishment to advance the public welfare. When then the commonwealth will derive more or as much advantage, or even will suffer nothing, from the remission of the punishment, this may well be remitted; and this consideration ought to be the measure and guide of the pardoning power. Forgiveness must come of course from the one who is injured, and that, in all states, is the sovereign. Clemency, says Montesquieu, is the distinctive quality of the monarch. The ultimate power, the real sovereignty, whether it reside in a king or in the people, as it is the

source of the law, so must it be the source of grace to him who breaks the law. In the forms of government which have most prevailed, the crowned prince has been regarded as the sovereign, and pardon has always been his prerogative. In democratic states, the people is sovereign; but in imitation of monarchies, and fitly enough, though not for any necessary reason, they have generally delegated the power of pardon to him who is placed at the head of the state; that is, to the chief executive magistrate. The constitution of the United States gives the power to the president alone. In some of the states it is to be exercised with the advice and consent of the council. Sometimes it is reserved to the legislature, and the governor can only relieve temporarily. Now, a pardon presupposes guilt and just condemnation, and works a suspension of a just sentence, and defeats and annuls, so far, the law which pronounced it. But it is the first principle of the best forms of government, that the law must be supreme; and it is at least inconsistent with this principle to suffer the enforcement or suspension of the laws to depend on the election of one man or of a body of men. When guilt is evident, the pardoning power can, as we have seen, be well exercised only when it is clear that the general welfare will suffer no detriment from the indulgence shown to the criminal. There are many and obvious reasons why this power may prove in its use prejudicial to the state. Indeed, those who are most conversant with the matter assure us, that in this country especially it is sometimes injudiciously and mischievously exercised. Yet, as we have already intimated, there is a power, generally called a pardoning power, though inaccurately so, because it is an act of justice, not of grace, which, if used discreetly, is only beneficial; and it is one which ought to exist in every state, in order to protect men from the accidental injustice which the laws must sometimes do. Owing to the imperfection of the laws themselves, or to the imperfect application of good laws, an innocent man may be condemned to punishment; or, at least, a slight offence may be visited with too severe a penalty. But remission of the sentence in these cases, whole or partial, according as the sentence is wholly or partially unjust, though regarded as an act of clemency, is, in the one class of cases, only that very justice which the courts in the particular case sought to do, and would have done if at the trial the proofs of innocence had been as clear as they now are; and in other cases, it is an equitable indulgence to those who, though within the letter of the law, yet, could their cases have been foreseen, would have been perhaps excepted from its general rules, or who ought to have been excepted but could never be, because of the necessary imperfection of legislation. But even in these cases, when justice alone is intended to be done, where the innocent, not the guilty, is to be relieved from penalties, it is hardly possible that the so called

pardoning power shall always be judiciously exercised. There must be one law for all the citizens of the state; and though it is very probable that the same law will not apply with equal fairness to all cases, yet it would be highly inexpedient to set any man or body of men over the courts, with discretionary power to revise their sentences, or to reform them, according to what he or they might consider the exact merits of each case. In short, in either view of the power of pardon, whether we regard it as it is exercised for the guilty or the innocent, its administration may easily become detrimental to the public. And as from the nature of the thing it cannot well be constitutionally or otherwise in terms limited, but must remain quite discretionary, the people, that is, the sovereignty which has delegated this power, ought jealously to scrutinize the exercise of it. —The indulgence of pardon extends only to crimes already committed. In no well governed state will the sovereign grant dispensation to crimes to be committed in the future; and in republics, unless the people, which is the sovereign, have expressly delegated such an authority, the executive, which is usually invested with the power of pardon, has no such right of dispensation. Further, as pardon is measured by and regards only the public welfare, it cannot intrude on private rights. Therefore a pardon which takes away other penalties cannot divest a private citizen's right in a forfeiture under a penal statute, or his share in the penalty which such statutes secure to the informer. On the principle that the greater power includes the less, it is well established, though it has been sometimes questioned, that the power of pardoning absolutely includes that of pardoning conditionally. Any conditions, therefore, precedent or subsequent, may be annexed to the offer of a pardon; and on the performance of these the validity of the grant may be made to depend. —In regard to the legal effect of a pardon, it may be observed that pardon in its proper sense completely rehabilitates the criminal; but usually the executive clemency consists only in a remission of part of the sentence. Now, if the judgment which the law passed upon the offender consisted exclusively in fine or imprisonment, remission of these does, in fact, restore him to full enjoyment of all his civil rights. But when infamy attaches by particular laws to the conviction, as it does in the case of felonies, forgiveness of the fine or imprisonment only by no means makes the pardoned equal with the innocent; in short, the pardon is partial, or it were perhaps better to say, it is no pardon at all. It must be remarked, however, that this distinction is not invariably recognized; yet the denial of it seems to have introduced a discordance into the decisions of the courts. Thus, in a Pennsylvania case, where the president of the United States had "remitted" to the party offered as a witness "the remainder of his sentence," it was held by the court that the par-

don, as it was called, removed the sentence and also the infamy which attended the crime, and therefore restored the competency of the witness. But in Massachusetts, in a precisely similar case, where, namely, the pardon "remitted the residue of the sentence," the court took the plain and just distinction between pardon and the mere annulling of a sentence of imprisonment, holding that the latter could not remove infamy and the consequent incapacity, because that could be effected only by an express forgiveness of the offence, that is, by words which distinctly imported a restoration to all civil rights, and showed the willingness of the pardoning authority to regard the criminal as entirely innocent. Quoting the language of an approved author on criminal practice, the court said the pardon, or rather remission of the punishment only, does not remove the blemish of character, and so does not revive competency. There must be full and free pardon of the offence, before these can be removed or revived. So the English law held that when attainder wrought corruption of blood, the party was not completely reinstated by the king's charter of pardon; and generally it has been laid down in this country, that commutation to a shorter period of a life term to the state prison (which in the American law generally works the civil death of the criminal) does not restore marital rights, or entitle the party to the guardianship of his children. Where these disabilities remain, the pardon is not complete. The distinction which we are stating is partially illustrated by the law of Rhode Island. In that state, persons who have been guilty of infamous crimes are deprived of their franchise of voting; and the constitution expressly declares that the governor's pardon shall not reinvest them with the forfeited right, but that they shall be enfranchised only by act of the general assembly. In other words, the power of pardon in these cases is so far reserved to the sovereign people, that it can be exercised only by a special act of the legislature. The executive can only remit penalties.—A pardon is regarded as a deed; and delivery and acceptance of it are essential to its validity in all cases, whether of capital offences or of misdemeanors.

PARÉ, AMBROISE, a French surgeon, born at Bourg-Hersent, near Laval, in 1509, died in Paris, Dec. 20, 1590. His parents were too poor to afford him a good education, but having learned Latin from a benevolent priest, he repaired to Paris in his 17th year with the resolution of becoming a surgeon. His progress in study was so rapid that in 1536 the captain-general of French infantry, René de Montéjan, appointed him surgeon to his troops and took him to Italy. On his return to Paris, he became a member of the college of surgery, of which a little later he was elected provost. His fame spread at home and abroad; in 1552 he was appointed surgeon to Henry II., and afterward attached in the same capacity to Francis II., Charles IX., and Henry III. Brantôme

relates that this last prince took good care to shield his surgeon, who was suspected of being a Huguenot, from the dangers of the St. Bartholomew's night, "keeping him in his own room and motioning him not to move therefrom." The fact, however, has been denied by Paré's latest biographer. However it may be, Paré commanded general esteem and admiration for his goodness as well as his professional skill. He is still considered as the father of French surgery, and his works are held of the highest authority, particularly on the subject of gunshot wounds. The first edition of his complete works appeared at Lyons in 1562, and the last, edited by Dr. Malgaigne, with historical and critical notes, at Paris in 1840-'41 (3 vols. 8vo.). They were translated into English by T. Johnson (fol., London, 1684).

PAREGORIC ELIXIR, or camphorated tincture of opium, a preparation of opium and benzoic acid, each 1 drachm; oil of anise, 1 fluid drachm; honey, 2 ounces; camphor, 2 scruples; diluted alcohol, 2 pints; macerated for 14 days and filtered through paper. This is a popular medicine, used as an anodyne and antispasmodic. It allays cough in cases of asthma and catarrh, relieves slight pains in the stomach and bowels, and has been extensively given to young children to induce quiet sleep.

PAREJA, JUAN DE, a Spanish artist, born in the West Indies in 1610, or according to Oean Bermudez in Seville, of parents who were slaves, in 1606, died in Madrid in 1670. The generally received opinion of his origin is that his mother was an Indian woman and his father a Spaniard. He appears at an early age to have become the slave of the painter Velasquez, who employed him about his studio, where, from frequent observation of the labors of his master, he imbibed a predilection for painting. Fearing to acquaint Velasquez with a taste which seemed so incompatible with his servile condition, he labored in secret to acquire a knowledge of the processes employed in painting, and almost denied himself sleep and rest in the attainment of this object. When he conceived that he had sufficiently mastered his art, he took advantage of a visit of the king to the studio of Velasquez to place one of his own pictures with its face against the wall. The king, as was his custom, asked to see the pictures so placed, and upon expressing surprise and pleasure with that of Pareja, the latter fell on his knees and implored the royal clemency for having presumed to practise painting without the permission of Velasquez. The king willingly interceded for him, and Velasquez not only forgave the transgression, but emancipated Pareja, who testified his gratitude by voluntarily serving his master during the remainder of his life. He was an excellent painter of portraits, imitating the style of Velasquez so exactly that their works of this class are scarcely to be distinguished, and also executed some historical pieces of merit.

PARENT AND CHILD. See INFANT.

PARENT DU CHÂTELET, ALEXANDRE JEAN BAPTISTE, a French physician, born in Paris in 1790, died March 7, 1886. He was graduated M.D. in 1814, practised medicine for some years, published in 1821 his *Recherches sur l'inflammation de l'arachnoïde cérébrale et spinale*, and, encouraged by Professor Hallé, then made public hygiene the main object of his labors. The results of 8 years' experience were embodied in his *Essai sur les cloaques ou égouts de la ville de Paris, envisagés sous le rapport de l'hygiène publique et de la topographie médicale de cette ville* (8vo., Paris, 1824). In another paper, drawn up in conjunction with D'Arcet the chemist, he discussed the influence of tobacco upon the health of the workmen employed in its preparation, maintaining that it was not deleterious. His last and most important work is entitled *De la prostitution dans la ville de Paris, considérée sous le rapport de la morale, de l'hygiène publique et de l'administration* (3 vols. 8vo., 2d ed., Paris, 1837).

PARHELIA. See HALOS.

PARIAHS, or **PARIARS**, a name employed among the Hindoos to designate the lowest class of the population. They are not properly a caste, being considered more impure than even the Soodras or servile caste, and are held in great abhorrence by the other natives. They act as scavengers, porters, and hostlers, and generally sell themselves with their wives and children to the farmers, who use them with extreme severity. A Hindoo who loses caste is ranked with the Pariahs, a penalty accounted worse than death. The Pariahs are supposed to be descendants of aboriginal tribes conquered ages ago, and are computed to comprise $\frac{1}{4}$ of the total population of Hindostan.

PARIAN CHRONICLES. See ARUNDelian MARBLES.

PARINACOCNAS, a lake of Peru, in a province of the same name, department of Ayacucho. It is about 20 m. in length, and lies in a depression between high mountains at an elevation of 10,000 feet above the sea. The river Pansa flows through it.

PARINI, GIUSEPPE, an Italian poet, born in Bosisio, near Milan, May 22, 1729, died Aug. 15, 1799. He was of humble parentage, and at first supported himself by copying. He published in 1753 a volume of poems under the name of *Riparo Eupilino*, which was so successful that he was admitted as a member of the *accademia dei trasformati* at Milan, and of the academy of Arcadians at Rome. The work on which his poetical reputation chiefly rests is entitled *Il giorno*, a didactic and dramatic satire. When Milan was occupied by French troops, he became an eager advocate of republican principles. His collected works, edited by Reina, appeared in 6 vols. 8vo. (Milan, 1801-'4), and in 2 vols. 8vo. (1825).

PARIS, the capital of France, and of the department of the Seine, built on both banks and on two islands of the Seine, 111 m. from the mouth of that stream; lat. of the observatory,

48° 50' 19" N., long. 2° 20' 23" E. of Greenwich; pop. in 1856, including a garrison of 25,000 soldiers, 1,525,942. In 1858 there were 37,451 births, of which 19,073 were male, 18,378 female, 11,757 illegitimate, and 2,899 still-born; 32,362 deaths, of which 19,845 were in private houses, 12,066 in the hospitals, and more than 600 suicides. The population in 1860 was estimated at 1,700,000. The city lies in a nearly level plain 190 feet above the sea, broken on the right bank of the Seine by a range of hills. As it gives its name to that series of geological formations which have become so interesting and well known to the scientific world through the investigations of Cuvier and Brongniart, so it has largely drawn the materials of its architectural rise and beauty from two of the strata of the Paris basin. This has for its base the great chalk formation, upon which rest the following layers in ascending order: plastic clay, marine limestone (of which Paris is chiefly built), silicious (fresh water) limestone, gypsum (the plaster of Paris of commerce) alternating with marls abounding in fossil remains and fresh water shells, sands, beds of millstone, and gravel and clay. It is estimated that 324,000,000 cubic feet of stone have been taken from the immense quarries that underlie nearly $\frac{1}{4}$ of the surface of Paris. Having furnished materials for the houses of the living, they began to be used as a receptacle for the bones of the dead, removed from the old cemeteries, in 1784, and took their present name of catacombs.—The climate is variable, but not unhealthy, moist rather than dry, with an average annual fall, in 105 rainy days, of 22 inches of water. Falls of snow are rare and slight. The mean temperature is 51° F., limited by the summer and winter extremes of 96° above and 1° below zero.—The first authentic recorded notices of Paris are found in the writings of Julius Cæsar. Upon an island in the Seine he found a town of huts, the stronghold of one of the 64 confederate Gallic tribes. Much ingenious conjecture has failed to clear away the obscurity that involves the etymology of its name, Lutetia, and the origin of its inhabitants, the Parisii. The former may be a Latinized corruption from three Celtic words, *Luth*, *Thonax*, *y*, or from two, *Louton* *Hesi*, signifying "a dwelling in the waters;" and the latter are thought to have been an offshoot from the Belgæ. They were a fierce race of hunters and warriors of the druidic faith. They burned their town rather than it should fall into the hands of the invaders in 55 B. C. When, soon after, physical resistance was overcome, they were still slow to yield to Roman laws and customs. The Parisian spirit of opposition to imposed authority is of old date. An insurrection broke out in 286, and its two leaders, upborne upon shields, were declared emperors by the people assembled near where the Hôtel de Ville now stands. About 360 the emperor Julian, who resided here for a time and has recorded his attachment to the place and its people in his *Misopogon*,

granted new privileges to the town, which rose to the dignity of a city and took the name of Parisia. It was for centuries the seat of a Roman prefect. Its trade was in the hands of a corporation, called the *nauta Parisiaci*, which long outlived the Roman dominion, contained the germs of a municipal government, and has left its symbolic mark, a galley with oars and sails, in the arms of modern Paris. The *palais des thermes*, considerable remains of which are still to be seen under and adjoining the hôtel de Cluny, was occupied by several Roman emperors when they visited the capital of the Gauls, which they made their head-quarters while their legions were endeavoring to repel the irruptions of the barbarians. As the vitality of the overgrown empire, diseased at heart, grew faint and fainter in its extreme members, Paris suffered greatly from these irruptions. It was stormed by Childeric in 465, and was saved from Attila's invasion in 451 only through the courage and wisdom of St. Geneviève, the noble precursor of Joan of Arc. (See *ГЕНЕВИЕВЪ*.) Near the close of the century, Clovis, the grandson of Meroveus, a Frankish heathen chief, took possession of Paris, embraced Christianity, espoused Clotilda, and built a church dedicated to St. Peter and St. Paul, which was soon after placed under the invocation of his wife's friend, St. Geneviève, who died in his reign and remains to this day the patron saint of Paris. He broke the last weakened bonds of Roman domination, and under him Paris became independently Frank. Under his feeble successors of the Merovingian dynasty, which lasted for 2½ centuries, Roman civilization died away. Meantime the church rose to the possession of wealth, political power, and social influence. According to a not improbable legend, Christianity was first preached at Paris, in the middle of the 8d century, by St. Denis; in the place and manner of whose death, on a hill far north of the limits of the town in those days, the faithful love to find the origin of the name of Montmartre, which other etymologists deduce from a temple of Mars that once stood on that mount. A chapel, dedicated to the true God and St. Stephen, was erected in the reign of Valentinian I., on the site of an earlier altar to Jupiter, now covered by the cathedral of Notre Dame. In the middle of the 7th century, St. Landry, bishop of Paris, founded what has since come, through great, beneficent changes, to be the hospital of Hôtel Dieu. The Carolingian monarchs, like their predecessors of the Merovingian line, rarely inhabited Paris. Doubtful legend and conjecture ascribe to Charlemagne the merit of having originated the university of Paris. The Normans repeatedly attacked the city in the 9th century, retiring down the Seine, now with rich plunder from its wealthy churches and convents, now with large ransoms paid by timid priests and citizens, in either case with stimulants to new incursions. The hardly pressed Parisians finally appealed for aid to

Eudes or Otto, count of Paris, whom, after he had repelled the invaders, they proclaimed king in 885. His successor 100 years later, of his blood but not his direct heir, was Hugues or Hugh Capet, the first king of France properly so called, from whom directly or indirectly descended all French monarchs down to Louis XVI. Paris now waxed in honors, privileges, wealth, influence, and population. The schools of Paris, illustrated by such teachers as Peter Lombard and Abelard, were resorted to by the youth of all Europe. The powerful order of the templars erected a fortress on the ground where the Marché du Temple, with its 2,000 dealers in old clothes and in every other conceivable second-hand article of economy—one of the most curious of the curiosities of modern Paris—now stands. The foundations of the cathedral of Notre Dame were laid. The city was to other cities of that time much what it is to-day to other European cities, if we may trust to the enthusiasm of John of Salisbury, who visited it in 1176 and wrote as follows: "When I saw the abundance of provisions, the gayety of the people, the good condition of the clergy, the majesty and glory of all the church, the diverse occupations of men admitted to the study of philosophy, I seemed to see that Jacob's ladder whose summit reached heaven, and on which the angels ascended and descended. I must needs confess that truly the Lord was in this place. This passage of a poet also came to my mind: 'Happy is he to whom this place is given as an exile.'" Philip Augustus (1180–1223) recognized the university as a corporation, and granted to its officers a jurisdiction, independent of the royal courts, over the quarter of the city to which it gave its name. He caused a new wall to be built about the town enclosing 625 acres; by a formal act he gave all the refuse straw of the royal apartments for the benefit of the patients of the Maison Dieu; he established two covered markets, and even ordered pavements for the streets. Louis IX. greatly promoted the welfare of Paris by important reforms of customs, laws, and police; by the establishment of many commercial, religious, and beneficent institutions, among which last were a hospital for the blind and a school of surgery. His chaplain, Robert de Sorbon, founded in 1250 a school of theology, the origin of the famous Sorbonne, in the quarter of the university still known as the Quartier Latin or Pays Latin. While King John, taken prisoner by the Black Prince, was held captive in England, the city was governed for a time by Étienne Marcel, the provost of the merchants, independently of the general state. For centuries before as for centuries after the brief reign of this popular leader, Paris was often disturbed by insurrections and popular tumults, and fierce quarrels between great lords and the king, or among themselves, with accompaniment of bloody fights and judicial massacres; its streets, despite royal reforms and new regulations of police

in frequent succession, were until modern times unsafe for honest citizens after nightfall. Under Philip IV. there were brilliant public fêtes, for which Paris seems thus early to have been distinguished, and "mysteries" were performed on stages set up in the open air, the first dramatic representations in Paris. Charles V. built a new palace, then called the Hostel de St. Pol, afterward famous in history, with change of destination and name, as the Bastille. The basement only of most private houses in those days was of stone; on this rested one or more stories of timbers filled between with mortar; when the proprietor's wealth permitted, the façade was covered with slates, and the projecting cornices and corner posts were adorned with carvings, representing foliage, fantastic animals, the heads of angels, and biblical personages. Chariots and even four-wheeled carriages, and disorders of swelling luxury, excess of gambling among the rest, are spoken of in contemporary documents. The city had overgrown its old limits, and the monarch caused a new fortified wall to be built, enclosing now 1,084 acres, to protect it against the incursions of the English; who, however, at the end of the sad reign of his insane successor, marked in the annals of Paris by pest, famine, and all the horrors of bloody faction, entered Paris amid Te Deum chants and great fêtes, and proclaimed Henry of Lancaster king of France and England. The enthusiasm of the occasion was only surpassed by that which greeted the entrance of Charles VII. after the expulsion of the English in 1436. About this date Greek was first taught in the university, which then numbered 25,000 students. In 1438 there were 5,000 deaths at the Hôtel Dieu, and in all the city 45,000; wolves prowled through its streets, desolated by war, plague, and famine. In 1466 malefactors and vagabonds of all countries were invited to fill up the broken ranks of its population, which numbered 800,000 souls before 1483, the close of the reign of Louis XI. This astute ruler favored trade and commerce of all kinds, protected against violent opposition the new art of printing and its connected industries, confirmed the privileges of the citizens, endowed the capital with its first special school of medicine, favored the first attempt at lighting its streets, and inaugurated the first rude postal system, putting it in communication with all parts of France. Under Francis I. (1515-'47) the advance of Paris in material prosperity, in arts and letters, in the refinements and in the vices of civilization, received a fresh impulse. The grim castle of the Louvre, commenced by Dagobert and repeatedly enlarged and strengthened by succeeding monarchs, was swept away, and the palace of the old Louvre as we now admire it begun upon its site; the Hôtel de Ville was commenced, new streets were opened, old quarters rebuilt, and a royal free college founded. The origin of the chateau and garden of the Tuileries, the endowment of the college of St.

Barbe, now one of the first high schools of Paris, and the effective constitution of what is now the imperial library, date from the reign of Henry II., in despite of whom a Protestant church also was established. The disasters of the so called wars of religion, culminating in the horrors of the St. Bartholomew massacre, fell heavily upon Paris, barring and repelling its progress in all directions. It revived under the rule of Henry IV. The palaces of the Tuileries and the Louvre were greatly enlarged, the Place Royale formed, and the Pont Neuf built. Under the reign of Louis XIII., or rather of his minister Richelieu, the Palais Cardinal, now Palais Royal, was begun. The Luxembourg palace, several fine quays and bridges, and numerous magnificent private hotels in the faubourg St. Germain, date from this period; as do also the *académie Française*, the *jardin des plantes*, and the college that afterward took the name of Louis le Grand. More than 80 new streets were laid out and many of the old ones improved in the long reign of Louis XIV., from which date also the academies, with the exception of the *académie Française*, the observatory, the opera, and the *comédie Française*, the Hôtel des Invalides, the eastern colonnade of the Louvre, the triumphal arches of St. Denis and St. Martin built on the site of ancient city gates, the laying out of the boulevards as promenades, the planting of the Champs Élysées, the enlargement of the Tuileries and the arrangement of its garden nearly as they now are, the forming of the Place Vendôme and the Place des Victoires, 38 churches, a founding hospital, the hospice of the Salpêtrière, the Gobelins tapestry manufactory, the first city post, the lighting of the thoroughfares with "lanterns placed from distance to distance" (which was commemorated by a medal bearing the legend: *Urbis securitas et nitior*), the rudiments of the modern omnibus (an unsuccessful invention of Blaise Pascal, in the shape of 7 coaches in which "even women took their places," for 5 sous, but from which soldiers and all persons in livery were excluded), and finally, to close the imperfect catalogue of innovations, the first coffee house in Paris. At the accession of Louis XV. Paris occupied a space of 3,919 acres, and counted 500 grand thoroughfares, 9 faubourgs, 100 squares and open places, 9 bridges, 22,000 private houses, of which 4,000 had carriage entrances (*portes cochères*), and over 500,000 inhabitants. The capital of science, art, literature, taste, and pleasure, not only for France but for Europe, it was the favorite abode and resort of philosophers, students, intelligent travellers, wearied idlers, of seekers of the most refined and of the grossest enjoyments, of adventurers of all sorts and degrees and nations and tongues. Paris was the laboratory where the great revolution was fermenting. But the political history of Paris belongs to the history of France, and is treated of elsewhere in its appropriate article. The growth of the city

had gone on in all ways during this period. The duke of Orleans, better known in history as Philippe Egalité, enclosed the spacious gardens of the Palais Royal with a continuous quadrangle of uniform architecture, whose galleries, furnished with shops of every kind, and coffee rooms, gambling rooms, and wine rooms, became one brilliant bazaar. The famous orgies of the regency in the palace proper were followed by revolutionary orgies in its gardens. It was, up to the first quarter of the present century, the central stage and sink of what was brightest and foulest in Paris. Toward the close of the reign of Louis XVI. the farmers-general of the city customs erected about the enlarged city an *octroi* or customs wall, enclosing an area of 8,124 acres, containing more than 50,000 houses, 987 lighted streets, 46 parish and 20 other churches, 11 abbeys, 138 monasteries and religious houses, 15 seminaries, 10 colleges, 26 hospitals and asylums, 60 fountains, and 12 markets. In the first years of the revolution many monuments of the middle ages were demolished or mutilated; the fine arts generally were neglected in the fierce struggle about more essential things; material growth was checked and the population diminished. But the ground was cleared for future improvements, and many of the institutions of which Paris to-day has best reason to boast date their origin from the revolutionary period; such, among others, are the museums of the Louvre, the bureau of longitudes, the conservatory of arts and trades, the polytechnic school, and the national industrial exhibitions held in Paris, to which are to be added radical vivifying reforms applied to existing establishments of art, science, literature, and charity. In the political order, the revolution completed the work on which Louis XI. and Richelieu and Louis XIV. had unconsciously labored; it swept away the last obstacles that impeded the French tendency to centralization. Out from its chaos was developed that centralizing political and administrative system, whose active sovereign control now extends to the remotest corners of France, vivifying and strengthening the nation and weakening individual action and capacity for action in equal proportion, and exalting the capital as it depresses the country at large. Although under Napoleon more than 100,000,000 francs were expended upon public works, many of them of public utility as well as ornament, several of the grander edifices begun by him were left to be completed by his successors. Under the restoration and Louis Philippe the growth of the city took a rapid extension. Encouraged by peace, private enterprise vied with government in enlarging and adorning the city. Better drainage and paving and lighting of the streets, and increased attention to comfort in domestic architecture, mark this period. The fertility of the intellectual movement was not yet exhausted, and material prosperity seemed at its height at the close of the reign of Louis

Philippe. The immediate effect of the revolution of 1848 was to check both. It is, however, from the republic that is to be dated the origin of the changes which, since reduced to a system, are now in course of execution on a scale unparalleled for extent in the material history of modern cities.—Old Paris, with its narrow, crooked streets, so favorable to disease and insurrection, so picturesque and so crowded with historical associations, is rapidly disappearing. The provisional government decreed that the Louvre should be finished, and the legislative assembly passed a law for the prolongation of the rue Rivoli; but little more than the preparation for these works was commenced before 1852. The republic was virtually suppressed by the *coup d'état* of Dec. 1851, and its name abolished when a year later Louis Napoleon had himself proclaimed emperor. It is perhaps natural that the only monarch of France born in Paris should surpass his predecessors in zeal for the embellishing of his birthplace. One of his early acts was to order to be done what Louis XIV. and Napoleon I. had labored at, the government of Louis Philippe had talked of, and the provisional government decreed, namely, the final completion of the Louvre, and its union with the Tuileries. The work was executed in 5 years, at a somewhat greater outlay of money than of taste; the ornamentation, for the style of architecture, is carried to excess. This is but an item of a stupendous plan of public works whose progress under the feverish impulse of the general government, together with an extraordinary activity of private enterprise, will in 10 years have transformed Paris almost past the recognition of those who only know it as it was 10 years ago. The limits of this article preclude a detailed description of this plan. Some indicative features of its nature and extent must be noticed. It aims at public utility as well as fine appearance, and to make of new Paris the most salubrious, convenient, and magnificent city of Europe, a monument of Louis Napoleon's reign, and a fortress for his dynasty. The central market is as grand in its kind as the new Louvre. While that palace was in progress the palace of industry was built. The new rue Rivoli was cut through a tangled labyrinth of narrow lanes, letting light and air into, and facilitating the circulation of business men and government troops through, a traditional stronghold of disease and insurrection. A grand new sewer runs under the new street. On the line of the street is the fine old Gothic tower of St. Jacques, about which, in place of the church long ago destroyed, were clustered tall houses disgracing and hiding its beauty. These were swept away to make room for a prettily planted garden square. At the end of the street is the Hôtel de Ville; the high buildings toppling over crooked lanes that formerly surrounded it were swept away, leaving it in a spacious open place, on one side of which palatial military barracks have been erected. Miles

of other broad avenues facilitating communication between all parts of the town; several other great barracks; the laying out of the parks of the Bois de Boulogne and the Bois de Vincennes; numerous gardens, squares, and fountains newly made or newly ornamented, in the most populous as well as in the fashionable quarters; 12 churches completed or in course of building, among which the Gothic structure of St. Clotilde is the most remarkable; 7 bridges; a connected network of sewers underrunning the city on both sides of the Seine, which discharge their contents into the river at Asnières through a grand trunk sewer 19 feet broad, 14½ feet high, and 2½ m. long; these are among the distinctive features of the public works urged forward by the emperor. The average yearly cost of their execution to the city treasury has been about \$2,800,000, from 1852 to 1859 inclusive. During that period, within the then limits of the city, 4,849 private houses were demolished and 9,617 constructed. The constructions are the result of private enterprise. The annual expenditure for carrying on the plan of public works for the 10 years following 1859 has been fixed by law at 18,000,000 francs, of which the state pays 5,000,000. This is entirely apart from the ordinary expenses of the city and the extraordinary expenses necessitated by the recent enlargement of its boundary. In 1859 the aggregate length of paved and macadamized streets was, in round numbers, 300 m., of which more than 200 m. were bordered with trees, gardens, or planted squares; of asphaltum or stone-paved sidewalks, 240 m. The streets were lighted with 15,160 gas lights and 487 oil lamps; they were cleaned and watered at a cost of \$844,000. The aggregate length of sewers was 122 m. On Jan. 1, 1860, the limits of the city were extended to the fortifications, incorporating the suburban towns and villages grouped about the old octroi wall, and a considerable expanse of open fields and gardens. The fortifications were constructed in the reign of Louis Philippe. They consist of a bastioned and terraced wall with 84 feet of escarpment faced with masonry, presenting 94 angular fronts, and a continuous ditch 22 m. in circuit and embracing both banks of the Seine. The system of defence is completed by 17 detached forts, each in itself a strong fortress. Within the fortifications is a continuous carriage road, and within that a railroad which connects with the 5 grand lines of railway that radiate from Paris to the boundaries of France. Paris now has an area of 18,315 acres.—The government of Paris is administered by the prefect of the Seine, assisted by a municipal council of 60 members, and by the prefect of police. All these officers are appointed by the emperor. For certain details of the civil service, the city is divided into 20 districts, each of which has a mayor and two deputy mayors subordinate to the prefect of the Seine. These districts are again divided into quarters, in each of which is a resident

commissaire de police, an inferior magistrate under the prefect of police. All sanitary regulations and measures for the preservation of public order are under the control of the prefect of police. Under his orders, composing the municipal police, are 4,590 agents, of whom 8,700 are *sergens de ville* or ordinary policemen. The sum of the yearly salaries of officers and men is \$1,266,000. Auxiliary to these are about 4,000 gendarmes, and the regiment of the *garde de Paris*, numbering 2,900 men. To meet emergencies, when this thoroughly organized force is unequal to the preservation of order, and always serving the prefect as a sort of base of operations, are 40,000 troops in Paris and its immediate confines. The barracks, the ministries of war and of the interior, the bureaux of the prefecture, and the imperial palaces are connected by telegraphic wires. A military corps of 1,800 officers and men, specially trained for the purpose, effectually perform firemen's duty for the city. On every article of consumption, on building materials, fuel, oil, &c., there is an octroi duty. The sum of these entrance duties in 1860 is estimated at \$18,400,000, which is shared between the treasuries of the city and of the state. The whole revenue of the city for 1860 is estimated by the prefect in round numbers at \$20,700,000, of which sum \$60,000 is raised by a "poll tax" of \$3 on 80,000 Parisian dogs; the amount of the city debt is \$26,482,000.—The prisons of Paris are 8 in number. They are regulated as far as possible in accordance with the bodily and spiritual wants of their inmates, who are furnished with decently healthful and clean food and lodging, with work, books, and priestly counsel. One of them, in the Boulevard Mazas, for persons awaiting trial, especially deserves its name of *prison modèle*, on account of its excellent construction and arrangement. To its other name, *la nouvelle Force*, it earned a new claim in Dec. 1851, when it became the temporary depot of Thiers, Lamoricière, and other distinguished victims of the *coup d'état*. Beside inferior courts and tribunals, there sit at Paris a court of assize, one of the 27 French courts of appeal; the court of cassation, a supreme court of appeal on points of law only; the *cour des comptes*, whose jurisdiction extends over all public receipts and expenditures, and safeguards the national treasury from loss by peculation or official negligence; and the high court of justice, which may judge, without appeal, charges of conspiracy against the government or of attacks upon the person of the emperor, by virtue of whose special decree alone its action commences.—The prevalent religion in Paris is the Roman Catholic. Beside 70 places of worship connected with public establishments, religious communities, &c., there are 72 parish churches served by 555 priests. The whole number of secular clergy is about 900. There are 19 religious communities of men and 53 of women, whose members are for the most part actively engaged in preaching, teaching, or in works of

charity. For worshippers of other creeds, there are 2 Jewish synagogues and 5 French Protestant temples established by government, with 10 Protestant chapels for foreign residents, 2 of which are supported by American contributions, and a church of the Greek rite. Many of the churches of Paris are remarkable for their architecture, or for their interior decorations, or for their historical associations. The cathedral of Notre Dame is a splendid cruciform edifice in the "early pointed" style of so called Gothic architecture; its greatest length is 390 feet, width of transepts 144, height of vaulting 102, width of western front 128, flanked by two massive towers 204 feet in height. Near by springs heavenward the arrowy subtle spire of *la sainte chapelle*, a gem of florid Gothic. St. Germain des Prés is a venerable specimen of the Romanesque style; that of the renaissance is grandly illustrated in St. Eustache and curiously in St. Étienne du Mont. St. Geneviève, an immense pile better known by its unconsecrated name of Pantheon, is distinguished for its Corinthian portico of columns 60 feet high, supporting a sculptured pediment. Its building was commenced by Louis XV. at the suggestion of Mme. de Pompadour. Beneath its pavement rest the remains of Voltaire and Rousseau. St. Germain l'Auxerrois, apart from its varied and rich ornamentation, claims attention because from its belfry was given the signal of the St. Bartholomew massacre; St. Vincent de Paul and Notre Dame de Lorette for their porticos and interior decorations; St. Gervais for its singularly beautiful chapel. St. Sulpice, St. Roch, and St. Otilde are among the noteworthy churches of Paris. The church of the Madeleine is a singularly grand and beautiful reproduction of pure antique forms. It stands on a raised platform 328 feet long by 188 broad, which is ascended at either end by a flight of 28 steps. A surrounding colonnade of 52 Corinthian pillars, each 49 feet high, supporting a richly sculptured frieze and cornice, intercolumnar niches in the side walls filled with colossal statues of saints, the largest sculptured pediment in the world, crowning the noblest portico the world has seen since the Parthenon, are some of the exterior features of this magnificent Christianized Grecian temple.—The charitable institutions of Paris are remarkable for their number, extent, and excellent administration. There are 23 civil, general, and special hospitals, 19 public *hospices*, 27 asylums or almshouses, and 8 military hospitals. The medical service is performed by the most eminent physicians of the capital; the gentler nursing, in large part, by sisters of some of the religious orders. The number of patients admitted to the civil hospitals in 1857 was 93,239, to the public *hospices* 9,877. In the prefect's report on the city budget for 1860, the appropriation for the beneficent establishments is \$2,000,000, which goes toward the support of nearly 18,000 beds. The city supports 1,600 insane persons in provincial

asylums, and furnishes outdoor aid or medical attendance to more than 124,000 poor. The number of persons employed by the city in the service of the poor, including 88 clergymen, 321 physicians, 42 surgeons, and 97 midwives, but exclusive of the religious sisters, is 3,682. —In the matter of common schools Paris is inferior to most large towns in the United States; but for educational institutions of a higher order it is deservedly distinguished. Nearly all of them where instruction is imparted by lectures are as freely open to all comers, native or foreign, as the public museums, libraries, and gardens. The 5 combined schools or faculties of the *académie universitaire*, the much changed descendant of the famous old university of Paris, are served by professors ordinary and extraordinary as follows: 21 of theology, 25 of law, 26 of medicine, 19 of letters, and 18 of the sciences. Their lectures are attended by between 7,000 and 8,000 professed students. The college of France has 28 professors of letters, philosophy, and science. The quality of instruction imparted may be guessed from the names of the lecturers, among which have been those of Ouvrier and Geoffroy St. Hilaire, Royer-Collard, Cousin, Jouffroy, Guizot, Michelet, and Villemain. Of the special schools peculiarly worthy of mention are: the *école polytechnique*, corresponding somewhat to the American military academy at West Point; the *école des ponts et chaussées*, for instruction in all branches of civil engineering; the *école des mines*, for a thorough instruction in every branch of art and science bearing upon mining operations; the *école centrale*, for the education of civil engineers, architects, and directors of manufacturing establishments; the *école d'état major*, for the education of staff officers for the army; the *école normale*, with 18 professors, for the education of teachers of the higher class; the *école des chartes*, where gratuitous lectures are given by a corps of learned professors on all branches of the curious art and science of palæography; the school of living eastern languages; the school of pharmacy, with a botanical garden and laboratory; the free school of design, mathematics, and ornamental sculpture; the free school of drawing for young women under the direction of Rosa Bonheur; the school of the fine arts, where gratuitous lectures are given by 21 first class professors and practisers of all departments of the plastic arts; the conservatory or academy of music and declamation, with 600 pupils, whose teachers are the best artists of the Parisian stage; the conservatory of arts and trades, the gratuitous courses of whose 17 eminent professors, treating of the application of science to the useful arts, are frequented by studious audiences of intelligent mechanics; 6 schools for the education of Roman Catholic priests, of which the seminary of St. Sulpice with 14, and that of Notre Dame des Champs with 17 directors and teachers, are the principal; and a seminary for the educa-

tion of Israelite pastors. The 5 imperial lycœums of Louis le Grand, Charlemagne, St. Louis, Napoleon, and Bonaparte, combine in the course of instruction many of the best features of American high schools and colleges. The colleges of St. Barbe and St. Stanislas are high schools organized on a grand scale. The colleges Rollin and Chaptal, as well as the *école Turgot*, are municipal establishments, where the course of study is shaped with special reference to the future career of the scholars in the ordinary paths of civil life. There are 30 large public libraries in Paris, 8 of which are daily open to all comers. The *bibliothèque impériale* is the largest library in the world. It contains more than 1,000,000 printed volumes, 300,000 pamphlets, 150,000 manuscripts, 300,000 maps, charts, and topographical views, 1,300,000 engravings, and a cabinet of coins and medals numbering 150,000 specimens. This invaluable collection is constantly increased by gifts and purchases, and by the action of a law as old as the time of Henry II. (1556), which requires the deposit of a copy of every new work printed in France. The libraries next in importance for their number of printed volumes and manuscripts are those of the arsenal, of the Louvre, the Mazarin, the city of Paris, of the Sorbonne, and St. Geneviève. The large libraries belonging to the schools, to the ministries of state, to the senate and legislative body, are rich in special departments of literature. They are not freely open to the public, but every reasonable application for access to them is granted in that spirit of courtesy and liberality which distinguishes the management of all public Parisian institutions. For an account of the celebrated academies composing the *institut de France*, see ACADEMY. The observatory of Paris has been described as the "head-quarters of astronomic science, a rendezvous of the learned, who seek for or discover planets, calculate eclipses and tides, and edit the *Annuaire du bureau des longitudes*." Its present director is Leverrier, who succeeded Arago. In its amphitheatre the latter delivered his admirable popular lectures on astronomy.—Beside its public establishments, some of the more important of which are mentioned above, there are in Paris about 60 charitable, literary, scientific, and artistic societies. The museums of Paris are among its distinctive features. Those of natural history connected with the *jardin des plantes*, which is the common name for a large zoological as well as botanical garden, are unrivalled in their kind; the scientific museums of morbid anatomy and comparative anatomy belonging to the medical school are remarkable for their extent and completeness; the museum in the Hôtel de Cluny (itself a curious specimen of the architecture of the middle ages, constructed partly upon the foundations of a Roman imperial palace) is consecrated to furniture, arms, and works of art of the middle ages and of the renaissance, and to some earlier Gallo-Roman antiquities; that

of the conservatory of arts and trades contains models of old and newly patented machines and tools, together with specimens of mechanical and chemical products, and of natural materials within the domain of industrial processes; in the museum of artillery is a collection of ancient and modern arms of defence and offence, from Indian hatchets to rifled cannon; the mineralogy of France, geographically arranged by her departments, is exhibited at the museum of the school of mines; the numismatic museum at the mint displays the coins and medals struck in France from Charlemagne's time to the present; the typographic museum, at the imperial printing house, contains a curious variety of ancient and modern printing, not the least remarkable of which are the productions of the imperial press, such as the Lord's Prayer in 150 different languages, and copies of *L'imitation de Christ* that seem the perfection of typographic art. The museums of the Louvre, worthily occupying all of that magnificent palace that had been completed by the labors of successive French monarchs from Francis I. to the great Napoleon, are 12 in number; of these the most notable are those of painting, of drawings and engravings, ancient sculpture, modern sculpture, Assyrian antiquities, Egyptian antiquities, and Etruscan antiquities, to which are to be added large collections of rare specimens of the ceramic art, of exquisite carved work in wood and ivory, of jewels, &c. The picture galleries contain 1,300 paintings. Other European galleries are richer in the works of certain masters and of special schools, but none of them offers to the practical student, the connoisseur, and the simple lover of art, so comprehensive and instructive a view of all the schools. The galleries of the Luxembourg, occupying a small part of the palace of that name, are hung with 200 paintings by living French masters, by no means a complete exemplification of the present French school of art. The conditions of admission to all these museums are of the most liberal nature. Those of the Louvre and of the Luxembourg are freely open to all comers 6 days, and to artist copyists 5 days in the week. On Sundays and holidays they are thronged by all classes of the population. That taste which seems instinctive with Parisians is thus constantly cultivated. A certain artistic sense of form and color is common to all, and reveals itself on every hand—in the arrangement of goods in the shop windows, in the dress of females of every social class, in most articles of furniture whether for use or ornament, in the decoration of the brilliant coffee houses and restaurants, in the minor external details of domestic architecture (wanting as that of the present day is in the larger features of a beautiful or, indeed, of any distinctive style), in the laying out of the gardens, and in the purely scenic effects at the theatres. It is by the material revelations of this artistic sense that the attractive charm which Paris

exercises upon all strangers is to be explained. There are no means of arriving at an accurate census of the painters and sculptors of Paris; an indication of their number may be found in the fact that of some 1,800 painters whose works were offered and admitted to the biennial Paris *salon* or exhibition of fine arts in 1859, more than 1,000 resided in the capital. It is hardly necessary to add, in view of the conditions of admission to the *salon*, that these were but a fraction of the whole number of unsuccessful applicants and non-applicants for that honor. —There are 28 theatres in Paris, 5 of which are musical, viz.: the grand opera, famous for its ballet and magnificent scenic effects; the *opéra comique*, which is properly the opera of the French; the Italian opera; the *théâtre lyrique*, subordinate to the grand opera; and the *bouffes Parisiennes*, devoted to musical broad farce. At the *comédie Française*, the French theatre *par excellence*, elocution, gesture, historical accuracy of costume, picturesque combination of stage groups, and whatever else contributes to the perfection of histrionic art, are exhibited in unrivalled completeness. This theatre also fills now the place of the ancient royal court, as the model school of French accent and pronunciation. To help to support this and 3 or 4 other theatres, the state makes an annual appropriation of about \$300,000. The total receipts of the 19 first theatres of Paris in the year closing with the month of April, 1860, an exceptionally bad year for Paris theatres, amounted in round numbers to \$2,070,000. The legally taxed "right of authors," in addition to any sums paid them by virtue of private bargains with the managers, amounted for the same period to \$213,000. New works by 234 dramatic authors and 40 musical composers were brought out in the course of that period. The theatres of Paris can, and of a rainy Sunday night do, seat about 30,000 auditors; in the orchestras are 680 musicians, and on the stages are more than 2,000 performers, 700 of whom more or less fitly fill the parts of actors proper, while the rest are choristers and walking characters. Paris offers 150 other roofed or at least laterally enclosed places of amusement, circuses, concerts, café concerts, concert gardens, ball rooms, dancing gardens, and others, with an average daily or nightly attendance of 24,000 persons. —Yet more frequented by the Parisians, one of whose chief pleasures is to meet with more Parisians, and be admired by strangers, are the public squares, gardens, and promenades. A remarkable series of these begins with the exterior gardens of the Louvre, whence lofty colonnaded arched ways give entrance to the grandly beautiful palace court; beyond is the garden of the Place Napoléon, surrounded by the excessively ornate inner façades of the new wings of the Louvre, except on one side, which opens on the Place du Carrousel; this is an immense palace court, whose principal ornament is a triumphal arch, designed after the arch of Septimius Severus at

Rome, adorned by 8 Corinthian columns of red marble with bronze bases and capitals, and surmounted by a triumphal car and 4 bronze horses, modelled from the horses of the piazza of St. Mark in Venice. The W. side of this court is enclosed by the main body of the palace of the Tuileries, whose western front, 1,000 feet long, looks on the gardens of the same name, with their flowers, fountains, statuary, orange trees, and groves of horse chestnut trees. Next to these is the finest square in Paris, originally named Place de Louis XV., then baptized as the Place de la Révolution in blood flowing from the guillotine set up there in the reign of terror, and now called Place de la Concorde. It is adorned with balustrades and rostral columns and 8 pavilions surmounted with allegorical figures of the principal towns of France. In the middle of the square, between two magnificent fountains, rises the obelisk of Luxor, a monolith 72 feet in height, first set up in front of the great temple of Thebes 84 centuries ago by the great Sesostris. On the N. side of the place are two fine edifices, each 288 feet in length, with colonnaded fronts resting on a basement of arcades; they are separated by the rue Royale, 90 feet wide, which opens a view of the portico of the Madeleine. To the south and on the left bank of the Seine, crossed here by a noble bridge, are the palaces of the legislative body and of the ministry of foreign affairs, behind which are seen the gilded dome of the Invalides and the spires of St. Clotilde. On the W. side, between two groups in white marble by Coustou, each representing an impatient horse restrained by an attendant, is the entrance to the grand avenue of the Champs Élysées, which is a mile and a quarter in length. The Champs Élysées are planted with trees and laid out in *parterres* profuse with flowering plants and shrubs. Here are cafés, open air concerts, marionette theatres, apparatus for children's games, and a hundred tasteful booths stored with playthings and toothsome refreshments, and on all pleasant days and evenings in the mild season a multitude of old and young, strolling or sporting under the trees, or sitting on the rows of chairs along the sidewalks watching the carriages and horsemen that throng the avenue. For other tastes there are a circus and a panorama; and in close proximity the most brilliant and notorious of Paris dancing gardens, Mabille and the *château des fleurs*. On the Champs Élysées also is the *palais de l'industrie*, originally built for the exhibition of arts and industrial products in 1855, whose ample spaces are now used for the national exhibitions of industry, horticulture, agriculture, and the fine arts, some one or more of which is held there yearly. Midway in its course the avenue spreads into a circular place called the *rond point*, adorned by a large fountain, and thence continues, bordered now by stately houses, to the Place de l'Étoile. Here is the triumphal arch, commenced by the first Napoleon as a monument

to himself and the *grande armée*, but only finished by that peace-loving monarch, Louis Philippe. It is the grandest structure of the kind in the world, rising in harmonious proportions from a base of 147 by 78 feet to a height of 162 feet. Its central archway is 45 feet broad and 90 feet high. Its inner walls are inscribed with the names of 384 generals and 96 victories. Its most striking sculptured ornaments are 4 groups of colossal figures in high relief, one of which by Rude, allegorizing the departure of the army in 1792, seems inspired with all the force and passion of that time. Radiating from the Place de l'Étoile are 10 streets and great avenues. One of these is the Avenue de l'Impératrice, which consists of a carriage way, foot walks, and a bridle road, nearly a mile long, and in all 800 feet wide, bordered by continuous gardens, outside of which on either hand is again a carriage road, and yet beyond are gardens and villas. It leads to the Bois de Boulogne, an extensive park just outside the fortifications, laid out since 1852 in the modern style of landscape gardening. Its winding roads, mazy paths, and shaded groves are the resort of the high, fashionable, and doubtful worlds, in fine equipages and on blood horses, and of all the other worlds of leisure of Paris, in *voitures de place*, on hired hacks, and on foot. Its largest artificial lake is $\frac{1}{2}$ of a mile in length. A fine race course and the zoological and botanical garden of the society of acclimation are embraced within its limits. At the opposite extremity of Paris is the Bois de Vincennes, recently embellished with new plantations and artificial lakes and streams, for the use of the inhabitants of the eastern quarters of the town. It is noticed of Paris, as of London and several other large cities, that its wealth and fashion tend westward; the faubourg St. Germain, the quarter of the aristocracy of ancient birth, on the left bank, and the faubourg St. Honoré and the Chaussée d'Antin, the quarters of the newer nobility and of the aristocracy of wealth, on the right bank of the Seine, are on the western side of the town.—The cemeteries of Paris are outside the octroi wall, the interment of the dead being prohibited within the city. The principal are those of Père la Chaise, covering about 100 acres on the E. side of the city, beautifully laid out, and planted with cypress trees (see CEMETERY); Mont Parnasse, to the W. of the observatory, in which are buried the remains of many persons executed for political offences; and Montmartre, on the slope of the eminence from which it receives its name.—The most attractive and peculiarly Parisian promenade is the *boulevard intérieur*. It is a continuous street, divided only by name into 12 parts, that follows for 8 m. the irregular line of what were once the fortifications, *boulevards* or bulwarks, on the northern side of the ancient city. The 4 westernmost and finest portions of this magnificent and incomparable street are the Boulevards de Montmartre, des

Italiens, des Capucines, and de la Madeleine. On them, or close at hand in the streets opening upon them, such as the rue Royale, the rue de la Paix, the Chaussée d'Antin, rue Lafitte, the rues de Vivienne and de Richelieu, are shops with the costliest silks, rarest jewels, and finest works of art, tastefully arranged; restaurants with the dishes most provocative of appetite and cafés wainscoted with mirrors; the great banking houses; the principal opera houses and the best theatres; the most fashionable churches, equipages, and pedestrian loungers of the town. "France is the centre of civilized nations, Paris is the centre of France, and the Boulevard des Italiens is the centre of Paris!" says an enthusiastic Parisian. The Boulevard Sébastopol is a broad business avenue and air channel 8 m. long, crossing the Seine and the island of the Cité in its straight course from north to south. The somewhat monotonous lines of its 6-storied, balconied, light-colored new stone houses are frequently relieved by gardens, fountains, places, monumental façades of public buildings, and ancient edifices of a higher architectural style. The *boulevards extérieurs* are an uninterrupted series of broad streets planted with trees of an aggregate length of 17 m., following the line of the old octroi wall and surrounding the city as its limits existed up to 1860. The *passages* are great resorts for loungers. They are galleries with glazed roofs and marble pavements, lined with shops and cafés. The most elegant of them, as the passages des Panoramas, Jouffroy, Vivienne, de l'Opéra, Choiseul, Colbert, du Saumon, &c., are, especially at night, among the most cheerfully brilliant of Paris phenomena.—Paris is eminent among modern cities for its monumental edifices. The municipality alone has at its charge the preservation and embellishment of more than 700. Any thing like a detailed description even of the most remarkable of them is precluded by the limits of this article. To convey a notion merely of the extent of the united palaces of the Louvre and the Tuileries, it will be enough to say that the greatest width of this immense pile of building is 1,008 feet; that the distance from the eastern colonnade to the western front is half a mile; that its roofs cover, beside the museums of art mentioned above, a library of 80,000 volumes, quarters for several regiments of troops beside the *cent gardes*, the offices and private apartments of the minister of state, the private and state apartments of the emperor and his household, the imperial chapel and theatre, and palatial stables for imperial horses. The Élysée Napoléon, now an imperial palace, was built early in the 18th century by a private nobleman; was then purchased and for a time occupied by Mme. de Pompadour, who added to its pleasant garden a part of the Champs Élysées; was afterward the residence of ambassadors extraordinary sent to the court of France; then fell into the possession of the famous banker Beaujon, and

passed from him to the duchess of Bourbon; was used as a government printing office during the early years of the revolution, and was next sold to private speculators, who converted it to a place of public amusement; was afterward bought and occupied by Murat, till he left it to become king of Naples, when it fell again into the hands of government, and was a residence at different times of the first Napoleon. It has been inhabited by the duke of Wellington and the Russian czar, Alexander I.; Louis XVIII. gave it to the duke of Berry, after whose assassination it descended to the duke of Bordeaux; after Dec. 1848, it took the name of *Élysée Nationale*, and became the official residence of the president of the republic, who, as he changed his condition, changed the often changed name of this pretty, habitable-looking palace to its present style. It is destined by him to be the residence of the prince imperial. The first Napoleon destined for the residence of the king of Rome the palace of the Quai d'Orsay; Charles X. had work done upon this magnificent edifice, destining it for the place of French national industrial exhibitions; Louis Philippe completed it; the imperial council of state and the imperial court of treasury auditors now occupy it. By its side is the ornate little palace of the legion of honor, built in 1784 by the prince of Salm, who was guillotined in 1794, when the palace was disposed of by lottery, a journeyman hair dresser winning the palatial prize. The Luxembourg palace is remarkable for its combination of beautiful forms with solidity of construction. Beside the admirable but greatly incomplete gallery of the works of living French artists, this palace contains the assembly room, library, and chapel of the senate, a gaudily decorated throne room, and the apartments of the grand referendary of the senate. The gardens belonging to the Luxembourg are not inferior to that of the Tuileries. The hotels of the ministries have the grandeur of palaces; they contain the offices belonging to each department as well as the residences of the ministers. The private palace of Prince Napoleon in the avenue Montaigne is a minutely studied reproduction in architecture and decoration of a Pompeian house. The quays of solid masonry that bank in the river for 5 m. on either side, and the 21 bridges of stone or of iron, some of which are admirable specimens of architecture, are among the notable structures of the city. The prospect commanded from several of the bridges hardly has its equal, for impressive grandeur and beauty, among urban views. The bourse or exchange is a noble edifice, 212 feet in length by 126 feet in width. It is surrounded by a range of 66 Corinthian columns, supporting an entablature and masked attic, and forming a broad covered gallery which is approached by a flight of steps extending across the whole front. These are daily ascended by about 3,500 devotees of Plutus. Near the bourse is the bank of France;

it has branches in the departments and in Algiers, and has the exclusive privilege of issuing bank notes in France. Paris is nearly as much the financial as the political centre of the country. It is the seat of the administrations of the 5 grand railways, which, with the numerous branches they send out on their course from the metropolis to the limits of France, cover the land with a network of iron. The *crédit mobilier*, the *crédit foncier*, and other establishments whose financial or industrial operations are carried on in all parts of France and extend to foreign countries, have their direction bureaux at Paris.—Vauban said as long ago as the time of Louis XIV.: "This city is to France what the head is to the human body; it is the true heart of the kingdom." A witty foreigner has said in our time, alluding to the supremacy of the capital: "One might as well speak of what a man's legs think as of what the provinces think." It is the chosen residence of literary Frenchmen, and is one of the largest publishing cities of the world, for books in all departments of literature, for maps, music, and engravings. Of the 12,000 literary works of all kinds published in France in 1860, nearly all of any literary or mercantile importance were published in Paris; the same observation is true of 2,900 musical compositions, and of 2,700 single pieces, connected series, albums, &c., of engravings, lithographs, and photographs. Of periodicals of all sorts published in Paris there are more than 200; 15 of these are daily political newspapers.—There are no later authoritative statistics of the manufactures of Paris than those contained in the admirable report by Horace Say, published in 1851, of the results of the official inquiry set on foot by the chamber of commerce in 1847. Since that time the annexation of the *banlieue* has brought within the city limits a large number of manufacturing establishments, the population has risen from 1,000,000 to almost 1,900,000, and industrial enterprise has been greatly developed. With these three facts kept in view, the figures of Say are still worth regarding. The number of trades then in Paris was 325, practised by 6,500 employers or independent workmen, and by 205,000 adult male and 112,800 adult female operatives, beside 16,600 boys and 7,700 girls. The main branches of manufacture were: those relating to clothing of all sorts, with an annual product of about \$48,200,000; those for preparing food of all kinds, \$45,400,000; those of building and architecture, \$29,000,000; those of furniture, \$27,400,000; jewelry, \$18,000,000; hats, \$3,200,000; gloves, \$2,800,000; works in the useful metals, \$20,727,000. The sum total of annual production amounted to \$292,725,000. A new industrial census of the city, conducted under the auspices of the chamber of commerce, was commenced in 1860. It will require 2 or 3 years for its completion and the publication of its results. Of these results nothing can as yet be accurately estimated; but it is not very

hazardous to conjecture that the total of manufactured values in 1860 is nearly twice that presented by Say. Paris is celebrated for its jewelry and other goldsmith's work, watches, and ornamental bronzes; its boots, shoes, and gloves; its pianofortes, paper hangings, perfumery, artificial flowers, articles of female dress, and military equipments. Its mathematical, optical, and surgical instruments have a deservedly wide reputation for beauty and accuracy. The products of the Gobelins manufactory of tapestry and carpets do not enter into commerce. The manufactory belongs to government, and like the porcelain factory at Sèvres is not a rival but a beneficial model and pioneer experimenter of private enterprises. The government tobacco factory in Paris furnishes about one fifth of the snuff, cigars, and smoking tobacco consumed in France, to an annual value of nearly \$30,000,000. It appears by Say's report, that of the 65,000 master workmen, there were only 7,117 who employed more than 10 operatives, while there were 32,588 who either worked alone or employed but one man. A similar characteristic trait is observable in the method of conducting commerce in Paris. The manufacturer and retail merchant are often the same person. But if industrial and commercial enterprises are generally conducted on a small-scale than in London and New York, the proportion of capital to credit is larger, business operations are safer, and failures are more rare. The traditional caution of Paris commercial habits is, however, gradually wearing away. In the year ending June 30, 1859, there were formed 1,477 commercial and joint stock companies, representing an aggregate capital of \$7,764,000. The number of bankruptcies in the same period was 1,062. The largest demand on the manufacturers and merchants of Paris comes from the city itself. Next in order of value is its trade with the rest of France; then follow its important commercial relations with foreign countries. The Seine, the canals joining that river to the waters of the Rhone, Rhine, and Loire, together with the 5 grand trunk railways and their branches, connect the metropolis with every part of the country, with the staple towns of continental Europe, and with the ports of the Atlantic, the Mediterranean, and the North sea. The value of foreign and colonial goods entering into Parisian commerce in 1859 was \$14,620,000, exclusive of platinum, gold, silver, and copper, coined and uncoined, to the amount of \$13,980,000. The first 6 classes of imported merchandise were: coffee, \$1,930,000; hides, \$1,560,000; sugar, \$1,280,000, of which \$900,000 was colonial; Cashmere shawls, \$870,000; peltry, \$810,000; and cacao, \$680,000. There were imports in the same period to the value of \$9,300,000, belonging to what is styled *commerce général*, i. e., imports which arrived at Paris in transit, or were warehoused, the greater part of which finally enter into the special commerce of the city. The exports of Paris in 1859

amounted to \$56,400,000, exclusive of platinum, gold, silver, and copper, coined and uncoined, to the value of \$19,900,000. The principal exports, comprised under 46 general titles, are exhibited in the subjoined table, the values being given in round numbers:

Kinds of merchandise.	Value of exports.
Silks.....	\$14,433,000
Woolens.....	6,433,000
Haberdashery and buttons.....	6,293,000
Clothing and linen drapery.....	4,293,000
Articles fabricated of skins and leather.....	3,189,000
Pasteboard, paper, books, and engravings.....	1,531,000
Prepared skins.....	1,037,000
Cotton fabrics.....	1,441,000
Fancy articles (<i>articles de Paris</i>).....	1,271,000
Goldsmiths' and jewellers' work.....	1,211,000
Modes and artificial flowers.....	533,000
Perfumery.....	523,000
India-rubber goods.....	343,900
Musical instruments.....	373,100
Ornamental feathers.....	263,100
Clocks and watches.....	247,100
Gold in bars and leaf.....	63,200
Cudbear.....	31,000
Common carmine.....	11,340

Other miscellaneous articles, not included in any one of the important groups enumerated above, amounted altogether to the value of \$3,273,000, and to 4 per cent. of all Paris exports.—The people of Paris consumed during the year 1858, of wine, 32,250,000 gallons; of alcoholic liquids, 1,780,000 gallons; of cider, perry, and beer, 7,049,856 gallons; of butchers' meat, 205,513,877 lbs.; of other solid animal food, 17,451,084 lbs.

PARIS, also called ALEXANDER, a mythical Trojan prince, second son of Priam and Hecuba. His mother having dreamed during pregnancy that she brought forth a flaming torch which set fire to the whole city, he was immediately after his birth exposed on Mt. Ida, where a she bear suckled him for 5 days. A shepherd then took him home and brought him up as his own child. He grew up handsome, accomplished, and valiant, and when a dispute arose between Juno, Minerva, and Venus for the golden apple inscribed: "To the fairest," which Eris (strife) threw among the assembled divinities, the beautiful shepherd Paris, who was then tending his flocks on Mt. Gargarus, was selected by Jupiter to decide the quarrel. He awarded the prize of beauty to Venus, who promised him in return the fairest of women for his wife. Afterward he learned the secret of his parentage, was received by Priam as his son, and hearing of the surpassing charms of Helen, the wife of Menelaus, king of Sparta, sailed to Greece with a fleet, and, aided by Venus, carried her off to Troy. The noblest chiefs of Greece, who had formerly been her suitors, took arms with Menelaus to avenge this outrage, and thus began the Trojan war. Paris showed little of his accustomed courage in the siege, and was oftener found enjoying himself with music and the society of women than fighting before the walls. He twice met Menelaus in conflict; once he fled, and again he was defeated, but was borne away by Venus. He is said to have slain Achilles, or according to some accounts Apollo assumed

his form in order to kill that hero. Being wounded by Philoctetes with an arrow of Hercules, Paris repaired to his long deserted wife Enone, daughter of the river god Cebren, whom he had married before the abduction of Helen; but she refused to heal him, and he returned to Troy. Enone repented and followed him with remedies, but being too late to save his life killed herself in despair.

PARIS, JOHN AYTON, an English physician and writer on medical science, born in Cambridge, Aug. 7, 1785, died in London, Dec. 24, 1856. He commenced the study of medicine at the age of 14, subsequently entered Caius college, Cambridge, where he was graduated M.D. in 1808, and in the same year engaged in the practice of his profession in London, succeeding Dr. Maton as physician to the Westminster hospital. Soon afterward he settled in Penzance, Cornwall, where his practice was lucrative. He devoted considerable time to the study of the natural sciences, and founded the royal geological society of Cornwall. In 1817 he returned to London and commenced courses of lectures on the *materia medica* and the philosophy of medicine, the matter of which was subsequently reproduced in his "Pharmacologia" (8vo., London, 1819; 9th ed., rewritten, 1843). In 1844 he succeeded Sir Henry Hallford as president of the London college of physicians, which position he retained until his death. He was the author of a "Treatise on Diet" (8vo., London, 1827), a memoir of Sir Humphry Davy, and a popular little work published anonymously, entitled "Philosophy in Sport made Science in Earnest." In conjunction with J. S. M. Fonblanque, he published a work on "Medical Jurisprudence" (3 vols. 8vo., London, 1823). He also wrote upon the geology and soil of Cornwall, and was an accomplished chemist. During his residence in Penzance he invented the "tamping bar," an iron implement coated with copper, which enabled the Cornish miners to pursue their labors without danger of explosion from the sparks, evoked by the ordinary iron bar, igniting gunpowder or the inflammable gases of the mines.

PARIS, MATTHEW (Lat. *Matthæus Parisius*, or *Parisiensis*), an English chronicler, born about 1197, died in 1259. He was a Benedictine monk in the monastery of St. Albans; distinguished himself as a theologian, orator, poet, painter, and architect; and was sent by the pope on a mission of reformation to the monasteries of Norway, and Henry III. of England held him in great esteem. He had intercourse with the most eminent men of his age, and was thus enabled to gather valuable materials for the history of his adopted country. He wrote a universal chronicle, the 1st part of which has, perhaps, been placed at the head of that of Matthew of Westminster, while the 2d, to which alone his name has been affixed, comprises, under the title of *Historia Major*, the history of Great Britain from 1066 to 1259. He made use of the chronicles extant in his

monastery; and his account of the first 85 years of the 13th century especially is compiled from the "Flowers of History" of Roger of Wendover. The *Historia Major* was first printed by Archbishop Parker in 1571. The best edition is that of Dr. William Watts (fol., London, 1640; reprinted in Paris in 1644), with an addition continuing it to 1278 by William Rishanger. An English translation of this history by the Rev. J. A. Giles forms 8 vols. of Bohn's "Antiquarian Library." An abridgment of it, which Paris himself called *Historia Minor*, of which the autographic MS., ornamented with illuminations and maps, is preserved in the British museum, is now (April, 1861) in press, edited by Sir Francis Madden. Matthew Paris also left the "Lives of the two Offas, Kings of Mercia, and of 28 Abbots of St. Albans," beside *Addimenta* to his history included in Dr. Watts's edition.

PARIS, PLASTER OF. See GYPSUM.

PARISH (law Latin, *parochia*). In ecclesiastical law, this word has always meant, in England, a certain extent of territory, or "circuit of ground," committed to the spiritual charge of one parson, or vicar, or other ecclesiastical having cure of souls therein. All England is said to be divided into parishes, and they number about 10,000. The origin and early history of parishes are quite uncertain. Camden says they began in England about the year 680. Sir Henry Hobart refers them to the council of Lateran in 1179. Selden places their origin between these periods. It seems, however, that about 1,000 years ago, while every man was bound to pay tithes to the church, he paid them to whatever ecclesiastical division of the church he preferred. At least, if there was any law determining his choice in this respect, it is not now known; and Blackstone says expressly that the payment was arbitrary, every man paying where he pleased. But a law of King Edgar, about 970, seems to confine the payment to the parish to which the man belonged; and so it has remained ever since.—In the United States the word parish is of frequent use, but it does not mean precisely the same thing as in England, nor does it mean the same thing in all the states. The legal importance of parishes in England depends upon the fact that the rector of each parish is entitled to the tithes of agricultural produce within it, except so far as some qualification of this rule has been made by comparatively recent statutes. In this country tithes were never paid, or rather no legal obligation to pay them ever existed. But, from the first settlement of the country, we have had everywhere associations and bodies corporate or organized for ecclesiastical purposes, and these have been generally called parishes. In New England they were originally the same as towns; that is, the persons composing a town, and acting as a town in civil and political matters, also acted as one body in religious or ecclesiastical matters; and the parish had therefore the same territorial lim-

its as the town. Afterward, as the towns grew more populous, they were divided for ecclesiastical purposes into different parishes, which were still territorial and were contained within local limits. There are many such parishes now in most of the states. At length, however, as a diversity of religious sentiment became developed, all religious opinions standing on the same footing in law, parishes began to be formed of persons associated by similarity of religious sentiment and not mere nearness of residence, and therefore with little or no reference to their place of abode. These were called poll parishes, in distinction from territorial parishes. They are numerous everywhere, and in the large cities may be considered as having taken the place of territorial parishes, which are almost unknown there.—In Louisiana, the word parish is used to designate a district separated and defined by local limitation for merely civil and political purposes. These districts are analogous to counties in some states, and to townships in others.

PARISH, ELIJAH, an American clergyman and author, born in Lebanon, Conn., Nov. 7, 1762, died in Byfield, Mass., Oct. 15, 1825. He was graduated at Dartmouth college in 1785, studied theology under the Rev. Ephraim Judson of Taunton, Mass., and in Dec. 1787, settled as pastor of the Congregational church at Byfield, Mass., where he remained the rest of his life. Theologically he belonged to the party called in his day the Hopkinsian. He took a strong interest in politics, and in 1810 preached the annual election sermon, in which he so bitterly inveighed against the policy of the government, that the legislature refused to ask it for publication. It had, however, a large circulation. Beside a number of sermons and orations on various occasions, he published a "Gazetteer of the Eastern and Western Continents," in conjunction with the Rev. Dr. Morse (1802); a "History of New England" (1809); "System of Modern Geography" (1810); "Memoir of the Rev. Dr. Eleazer Wheelock, First President of Dartmouth College," in conjunction with the Rev. Daniel McClure (1811); and "Sacred Geography, or Gazetteer of the Bible" (1813). A volume of his sermons, with a brief memoir of his life, appeared in 1826.

PARK, originally in England a portion of a forest enclosed for keeping deer, trapped or otherwise caught in the open forest, and their increase. Grants for this purpose were made by the sovereigns to the nobles. Rich land of an open pastoral character, with trees sparingly distributed and having broad stretches of greensward pasturage, would naturally be chosen for this purpose; and this character would be intentionally increased by felling a portion of the trees, and unintentionally by the effects of the browsing of the confined deer. Hence the word is used to describe this sort of scenery. Parks of this character at length became very numerous. In the reign of Henry VII. there were in Kent and Essex alone 100

each of several miles in circumference. The earl of Northumberland possessed 21 in three of the northern counties, containing 5,771 head of deer, beside others in the south. At that time, tenants sufficient to cultivate the land being difficult to obtain, parks were enclosed from motives of profit. As the country became more densely occupied and the landlords more numerous, sites for residences were generally taken within the parks for their proprietors. Thus the mansion was originally fitted to the park, not the park to the mansion. Parks at length came to be considered luxurious appendages to the dwellings of the rich, and to be formed and planted for this purpose. There yet remain a large number of private parks of considerable size in England. There are more than 50 in the single county of Warwick, each from one to 5 m. in diameter. Most of these are open to the public with some reasonable restrictions, and in many cases the whole people of the neighboring farms and villages have rights of way in footpaths through them. Not unfrequently parish churches are situated in the midst of old private parks. Most of the parks formed and held for the king's use came gradually to be considered in a measure as public grounds. Even earlier than the reign of George II., the use of the park of St. James in the suburbs of London had been so long enjoyed and was so highly valued by the people, that when the queen asked what it would cost to transform it to a garden, suitable to be attached to the palace which fronts upon it, closing it to the public, Horace Walpole says that his father replied: "Only three crowns," meaning a revolution. As England has advanced from feudalism, and the power of the people has increased, the royal parks have more and more been adapted to the wants of the citizens.—Almost every large town in the civilized world now has public pleasure grounds in some form. Those of London are the following: Kensington gardens (262 acres), Hyde park (389), Green park (55), St. James's park (59), Regent's park and Primrose hill (478), Victoria park (248), Greenwich park (185), Battersea park (175), and Kennington park (85). The first four are in a chain (though not at all connected in plan), being partly separated by streets. There are also a great number of small pleasure grounds, termed squares, comprising about 1,200 acres. Beside these there are several large royal parks and grounds in the vicinity of London, much resorted to by its inhabitants; for instance, Windsor (3,800 acres), Hampton Court and Bushy (1,842), Richmond (2,468), and Kew (684). These can all be reached in less than an hour from the central parts of London, as can Epping forest, and several large commons, which are equally pleasure grounds for all the people. Thus, there are of free public pleasure grounds, within the town, above 3,000 acres, and suburban at least 10,000. In addition there are several noblemen's parks which are in

a measure open to the public, and the grounds of societies, as the horticultural and the crystal palace, to which the public are admitted on payment of a gate fee. The crystal palace company's grounds comprise 200 acres, laid out by Sir J. Paxton, and 50,000 visitors have been in them at one time. The number ordinarily using the public parks of London has not been accurately ascertained, but on certain Sundays when music has been performed more than 100,000 persons have been counted at the gates of Victoria park in a day. The largest number counted was 180,000 in a day, in 1857. The fashionable drive of London is the Ring road in Hyde park; it is about 8 m. in length, and varies from 27 to 60 feet in width, the part most used (between the principal entrance and the Serpentine) being 36 feet. There is another drive a mile in length in Hyde park, which is also 36 feet wide. The fashionable riding course of London is in the same park, and is popularly called Rotten Row, a corruption of *la route du roi*, or the king's road, its official name; it is 90 feet wide, and a mile in length. Kensington gardens, Green park, and St. James's are only skirted by carriage roads, and there is but little carriage road in either of the other metropolitan parks. That of Victoria park is but 22 feet wide, and seldom crowded.—Phoenix park at Dublin (1,752 acres) is a fine upland meadow fringed and dotted with trees. In its natural character it is the best public park in the world, but it is badly laid out and badly kept, being much larger than the town requires or than government can afford to maintain for it. Birkenhead park is a piece of ground of 185 acres in a suburb of Liverpool, and is surrounded by villas the grounds of which connect with it. Though small, it is by its admirable plan the most complete, and for its age the most agreeable park in Europe. It was designed and its construction superintended by Sir Joseph Paxton and Mr. Kemp. Birmingham, Manchester, Bradford, and other manufacturing towns of England have each recently acquired parks by subscriptions of citizens or by joint stock companies formed under the limited liabilities act. To that at Birmingham a charge of a penny is made for entrance, and this affords a fund by which, after the payment for improvements and maintenance, the cost of the land is being rapidly defrayed; as soon as paid for the admission will be free. At Halifax an admirable park has been formed and given outright to the town by a benevolent citizen. Derby is provided in the same way with an arboretum. Most of the small towns of England have some place of general promenade, as for instance the old city walls and the river bank above the town at Chester, the common and the old castle grounds at Ludlow, the castle garden and the cathedral grounds at Hereford, the river banks at Lincoln, and the cathedral green at Salisbury and Winchester. These consist in each case either of a long, broad walk, pleasant-

ly bordered and leading to fine views, or a few acres of smooth turf well shaded, where, after church on Sunday or on a fine summer evening, considerable numbers of the largest classes of the people may always be seen in their best presentation of themselves. Most villages in England have a private park near them which the people are allowed to use; when this is not the case, it is rare that even a hamlet is found that has not at least a bit of cricket ground or common, where, on benches under a patriarchal oak or elm, the old people meet to gossip and watch the sports of the vigorous youth.—The old towns of the continent have generally provided themselves with pleasure grounds by outgrowing their ancient borders of wall and moat and glacis, partly razing the wall, filling part of the moat, and so, with more or less skilful arrangement of the materials, making the groundwork of a garden in the natural style. This is done admirably at Frankfort, Leipsic, and Vienna. Elsewhere, simple broad roads bordered with trees have been laid out upon the levelled ramparts, as is the case with the circuitous portion of the boulevards of Paris. The boulevards of Brussels are simply straight streets about 125 feet wide, and with in some cases different classes of communications running through their length, each divided from the other by a row of trees; one, for instance, has on the outside a gravelled walk 21 feet wide, next a macadamized carriage road 36 feet wide, next a soft gravelled horseback road 21 feet wide, next a paved business road 30 feet wide, and then another walk, which is perhaps flagged for rainy weather. Town houses of a good class front upon this boulevard, removed from the too close observation of promenaders by the interposition of small private gardens or forecourts. Brussels also has an old park and two botanical and zoological gardens.—The newly formed Avenue de l'Impératrice at Paris is a straight promenade, between Paris and the Bois de Boulogne. It consists of a carriage way 60 feet wide, there being a pad for saddle horses on one side and a gravelled walk on the other, each 40 feet wide, and separated from the carriage road by a simple wooden hand rail; on the outside of all is a slope of turf planted in the rear with groups of trees and shrubs in the natural style; back of this, on both sides, a narrow road adapted to heavy traffic is carried, which also gives access to a line of detached villas, the grounds of which, being outside of all, form the background of the view from the promenade. The Bois de Boulogne is an ancient royal forest of some 2,000 acres, in the suburbs of Paris. The soil is naturally sandy and poor, and the scenery flat and uninteresting. The trees are generally thickly grown, stunted, and weak. Several departmental roads, broad, straight, paved wagon ways, pass through it. Except its vicinity to Paris, and the refreshing wildness of a large and entirely untrimmed forest, it offered as late as 1855 but little to attract

a visitor. It was, however, already a favorite resort of the Parisians, and Napoleon III. saw in the very neglect to which it had been abandoned the opportunity of making one of those sensations, to the frequent succession of which he owes so much of his popularity with his subjects. The coarse silicious soil, although unfavorable to fine old trees, is much less costly to handle than better earth, and its form may be remodelled with ease and rapidity. Good roads are cheaply graded in it, and the materials of a sufficiently firm superstructure for so porous a base may be had on the spot by simply screening its pebbles; for the same reason scarcely any artificial drainage, so important in heavy soils, is necessary. There were some large open meadows in the vicinity reaching to the banks of the Seine. All these circumstances were skilfully taken advantage of, and the various opportunities they afforded for the purpose in view adroitly combined. Possession was obtained of the meadows, and roads cut through the old wood in such a way as to lay open all that was most agreeable in it, at the same time bringing its close scenery before the visitor in rapid alternation with the open expanses of the meadows. Long and narrow lakes, the largest having two long and narrow islands in the midst of it, were excavated, and the excavated material thrown into hillocks along the shores. Thus, with but a very short removal of the light material, a very rapid change of scenery, and this in views of no inconsiderable distance, was effected. Rocks of soft stone were then selected at Fontainebleau, split into fragments convenient for transportation, floated down the Seine till opposite their intended site, and then moved to the banks and hillocks of the lakes and put together again in their original form. This, with an addition of artificial rock, made chiefly of water cement, and an admirable planting of evergreens, furnished bits of really picturesque scenery. Each of these pieces of rock-work, however, is only excellent in itself; they are rather studies of rock pinned against the landscape of the wood than naturally incorporated with it. The principal rock-work is much more like an operatic fairy scene than any thing in nature; and as its great size prevents it from being regarded as puerile or grotesque, like Chinese garden scenes, it may be considered to have been conceived in an original style to which the term romantic may be rightly applied. In its way it is admirably done. It contains 58,015 cubic feet of rock, and, with the reservoir of water behind it, cost upward of \$80,000. It furnishes a grotto through which during promenade hours a subterranean stream passes, forming at the mouth a cascade 82 feet in breadth and 27 in depth of fall, and using 176 gallons of water each second when in full flow. The water for this cascade, for the lakes, and for the sprinkling of the ground, is chiefly diverted from aqueducts constructed for the general supply of Paris. Some is obtained from the

Seine by a steam pump, and an Artesian well is under construction especially for the supply of the wood. All the above works, commenced in 1855, together with a race course and a great number of rustic architectural structures, the planting of 420,080 trees and shrubs, of which 1,550 were too large to be lifted by hand, and a general improvement of the surface throughout the wood and meadow, had cost, at the end of the year 1858, \$1,414,000; and no money ever better effected the object of its expenditure, nothing else done under the auspices of the present emperor being regarded by all classes of the people of Paris with such universal admiration and satisfaction. The Bois de Boulogne contains, with the meadow, 2,158 acres, thus divided: wood, 107 acres; open turf, 675; water, 74; roads, 265; nurseries and flower beds, 71. The length of carriage road is 36 m., varying from 24 feet 6 inches to 32 feet 8 inches in width; of bridle road 7 m., generally 16 feet in width; of walks 16 m., generally from 8 to 10 feet in width. Much of the wood is still in an unimproved state.—The Bois de Vincennes is a close natural forest on the opposite side of Paris from the Bois de Boulogne, the improvement of which in a manner similar to that of the latter was commenced some years ago, but has been discontinued. It encloses a vast plain used for heavy gun and shell practice, drilling in field fortification, and manœuvres on a large scale.—The garden of the Tuileries with the Champs Élysées forms the most magnificent urban or interior town promenade in the world. Its central feature is an avenue of horse chestnuts, which leads straight from the clock tower of the palace, through the Place de la Concorde, the Champs Élysées, and the triumphal arch, to the bridge of Neuilly, a distance of 8 m. In its centre, on the Place de la Concorde, stands the obelisk of Luxor, with fountains near it, and there are at different points other fountains which give brilliancy to its vista. On either side in the gardens are groves, shrubberies, and parterres of flowers; and in the Champs Élysées gay coffee houses, concert halls, and booths for the exhibition and sale of playthings. The garden of the Luxembourg is another interior promenade of Paris. It is also in the formal style, with a central avenue, groves, and flower beds, music and coffee houses, but is especially notable for its rose garden; it is about a mile in circumference. Both gardens are open to the public, and in fine weather an immense crowd of all classes of the people daily make use of the privilege. At certain hours thousands of children, attended generally by their nurses, may be found in them at play.—The interior pleasure grounds at Vienna have been already mentioned. Its principal rural promenade is the Prater, the chief feature of which is a straight carriage road, over a mile in length, with a walk on one side and an equestrian pad on the other. It contains near the town a great number of

coffee houses and play houses; but being 5 m. in length, considerable portions are thoroughly secluded and rural. Before the recent improvements of the Bois de Boulogne it was the most frequented park in the world, all classes of the Viennese, from the emperor to his most humble subject, resorting to it at certain seasons almost as if it supplied a necessity of life. The English garden at Munich was laid out under the inspiration of Count Rumford, by the Freiherr von Skell, and its scenery, in the English style, is more agreeable than that of any other large public park on the continent. It is about 4 m. long and half a mile wide. The Thiergarten at Berlin contains over 200 acres of perfectly flat land, chiefly a close wood, laid out in straight roads, walks, and riding paths. Its scenery is uninteresting. The Prussian royal gardens of Sans Souci, Charlottenburg, and Helligensee are all extensive grounds, the two former in mixed, the last in natural style. The public gardens of Dresden, Stuttgart, Hanover, Brunswick, Baden, Cassel, Darmstadt, Gotha, Weimar, Worlitz, Schwetzingen, Töplitz, Prague, and Hamburg, are all worthy of mention. Coffee houses are important adjuncts of all the German public gardens. The refreshments furnished are generally rather coarse, but of a wholesome sort, and the prices very moderate. Many families habitually resort to them for their evening meal, especially when, as is frequently the case, there is the additional attraction of excellent music furnished by the government. The gardens of Antwerp, the Hague, and Warsaw are also remarkable.—The famous summer gardens of St. Petersburg are not extensive, being but half a mile in length by a quarter in breadth, and formal in style. They contain very fine trees, are rich in statuary (boxed up in winter), and are the most carefully kept public gardens in the world, so that it is said a policeman watches every leaf to catch it, if it falls, before it reaches the ground. In the exceeding luxuriance, freshness, and vigor of the plants and flowers, and in the deep greenness of the turf, this care finds its reward. During the evenings of the short summer the garden is crowded with loungers, and it is here that the ancient annual wife fair is held; marriageable girls, tricked out with every evidence of wealth in trinkets which their parents can manage to obtain, standing for hours together, for the express and avowed purpose of affording an opportunity to those wanting wives to make their selection. The more fashionable promenade of St. Petersburg is in the gardens of Catharinehoff, where on the 1st of May "all St. Petersburg" turns out, and there is an endless procession of carriages headed by that of the emperor. The gardens are full of bowling alleys and restaurants. Many of the islands of the Neva contain pleasant gardens, both public and private, their chief distinguishing characteristic being the abundance of glass and the success with which exotics are cultivated.

One of the most remarkable gardens in the world is that of Tzarskoe Selo, in which is the residence of the imperial family, about two hours' ride from St. Petersburg. It consists of about 350 acres of diversified scenery, wooded and open, and contains, beside the palace, temples, banqueting houses, and theatres, a complete village in the Chinese style, a pyramid and obelisks in the Egyptian style, a Turkish mosque, a hermitage, and numerous monuments of military and other achievements. Notwithstanding this great and incongruous variety of artificial objects, beautiful and secluded rural scenery is not wanting. The keeping of the grounds employs 600 men, and costs \$80,000 per annum.—Stockholm has a great variety of delightful waterside rural walks, and the chief object of pride with its people is the Djurgard, or deer park, which is a large tract of undulating ground about 8 m. in circumference, containing grand masses of rock and fine old trees. It is beautifully kept. The Haga park, also at Stockholm, is very picturesque in character, and has the peculiarity of natural water communications between its different parts and the city, so that it is much visited in boats. The environs of Copenhagen contain many grounds of public resort, but the notable promenade of the city is the royal deer park (Dyrhave), a noble forest. In the midst is a large green where a great annual fair is held.—In all the Italian cities, the chief public rural resorts are gardens attached to the villas of ancient noble families. The *cascine* of Florence are pastures of the ducal dairy, on the banks of the Arno, passing through which are broad straight carriage drives. These contain little that is attractive within themselves, but command delicious views. At a space where the different roads concentrate, a band of music usually performs at intervals during the promenade hours; and it is the custom for carriages to assemble just previous to the commencement of each piece of music, and rapidly disperse at its end, taking a short drive and returning. The fashionable carriage drive of Rome is on the Pincian hill, which has little natural attraction except in its magnificent distant views. At Naples the fashionable world turns out in carriages upon a broad street called the Riviera di Chiaja, near the bay, but separated from it by the public garden of the Villa Reale, the length of which is about 5,000 feet, breadth 200. The garden is partly in the Italian and partly in the natural style; but with the bay of Naples to look out at, the visitor finds little in its scenery to hold his attention.—Most Spanish and Portuguese towns, and towns founded anywhere in the world by the Spanish and Portuguese, are provided with a place of promenade under formal avenues, to which at certain hours custom brings the ladies in open carriages and gentlemen on foot or horseback.—In the United States there is, as yet, scarcely a finished park or promenade ground deserving mention. In

the few small fields of rank hay grasses and spindle-trunked trees, to which the name is sometimes applied, the custom of the promenade has never been established. Yet there is scarcely a town or thriving village in which there is not found some sort of inconvenient and questionable social exchange of this nature. Sometimes it is a graveyard, sometimes a beach or wharf, sometimes a certain part of a certain street; sometimes interest in a literary or a charitable, a military, or even a mercantile enterprise, is the ostensible object which brings people together. But in its European signification the promenade exists only in the limited grounds attached to the capitol and to the "white house" at Washington, and in the yet half-made park of New York. It is a remarkable fact that in the second year after any portion of the roads of the latter are open, and while they are still incomplete and encumbered with the carts of the workmen, and there is but the faintest suggestion of park scenery, the promenade seems to have been fully established as an institution of the city. There are indeed few gayer or better attended promenades in Europe, it having been not at all unusual during the last year (1860) for 2,000 carriages and 10,000 persons on foot to enter the gates of a fine autumn afternoon, while, although 5 m. distant from the city hall, 100,000 have been drawn to it on special occasions. The central park of New York is being formed on two pieces of ground a little less than a mile apart, one of 331 acres, the other of 166, connected by two narrow strips containing together 137 acres, between which stand two great artificial reservoirs of water for the supply of the city, which occupy 142 acres. The park enclosure will therefore contain 776 acres, to which an addition of 66 is contemplated. The site of the central park, having been chosen on account of the impracticability of extending the ordinary street arrangements of the city over it, presents great obstacles to satisfactory park arrangements. In overcoming these, many peculiarities, by which it will be distinguished from all other parks, must result. The plan, which is still incomplete in details, contains about 9 miles of carriage road, 5 of bridle road, and nearly 20 of walks. A lake, which, with many deep bays, occupies 20 acres, is furnished with pleasure boats in summer; and in winter, its depth being reduced to 4 feet, at which elevation its banks are terraced, forms a skating field to which sometimes as many as 50,000 persons have resorted in a day, furnishing a scene of gayety and intricate motion almost without parallel. Fifty acres in different parts of the park are prepared especially for the recreation of ball playing. A district called the ramble, which can only be entered on foot, consists of a series of walks carried, in constantly changing grades and directions, through 30 acres of ground of very diversified character, the aspect of natural arrangement being everywhere maintained, while the rich-

ness of cultivation is added. The profusion of rocky surface, without the barrenness of vegetation which usually accompanies it, renders this very interesting and attractive; and, in the incomplete condition of the rest of the park, it is often inconveniently crowded. At a point where the best interior view of the park is to be had, exterior scenes being obscured, and where the various communications are so arranged that visitors must pass near it, a series of terraces, staircases, and arcades, offer temptations and facilities for a large number of people to tarry, and so dispose of themselves while resting or lounging as not to be in each other's way. This is effected by a peculiar architectural arrangement, the details of which themselves invite observers to leisurely contemplation. Mr. F. L. Olmsted and Mr. C. Vaux are the designers of the plan, which was obtained by a remarkable competition, the commissioners appointed to lay out the park having offered premiums, amounting to \$4,000, for the best, which induced 35 studies to be presented to them, some coming from Europe. It is chiefly remarkable as an effort to reconcile the necessities of a park which is to be the centre of a crowded metropolis with scenery, the predominating quality of which shall be rural and in some parts even rudely picturesque. Its purely constructive features are for this purpose kept below the general plane of sight, and to some extent are completely subterranean. Its artistic intentions are described in a recent report of a legislative committee to be, "in the first place, to obtain large unbroken surfaces of smooth meadow-like ground wherever the natural obstacles to this mode of treatment are to be overcome, even by heavy expenditure. The immediate borders of these spaces are planted in a manner to hide or disguise any incongruous quality in the grounds beyond. The rocky and broken surface which originally characterized the whole site, however, admits of the application of this evident preference of the designers to but a small portion of the grounds thus far finished; and elsewhere its capabilities for picturesque effects have been revealed. The different classes of communications are so arranged that, by a peculiar system of arched passages, it never becomes necessary for a person on foot to cross the surface of the carriage roads, or the horseman's track, or the horseman to cross the carriage roads, though he may ride upon them if he prefer."—Philadelphia, Baltimore, Brooklyn, Hartford, and Detroit have each recently taken steps to obtain a park. In Philadelphia some fine old villa grounds, beautifully situated on the Schuylkill near the Fairmount water works, have been purchased. These contain 128 acres, upon which operations adapting them to public purposes have been commenced, and it is intended to add to them 80 acres on the opposite bank of the river, the two sections to be connected by bridges. The alterations to be made are

designed and superintended by Messrs. Sidney and Adams. There are fine trees already on the grounds, and they possess many very valuable advantages in position, character of soil, and beauty of natural surface. At Hartford a competition of plans was held, but the committee having the matter in charge were dissatisfied with all that were offered, and undertook to form one for themselves which should avoid all the objections they found to each of them. The result was an ill-digested design, badly fitted to a rather difficult piece of ground. At Baltimore, Mr. Daniels, who had previously laid out a number of rural cemeteries, has been employed to adapt a very beautiful old private park to public purposes. The Brooklyn park commission is acting under the advice of Lieut. E. L. Vié, formerly of the U. S. army, but has not yet adopted a plan. Mr. Olmsted has been consulted with reference to the Detroit park, but nothing is yet determined in regard to it. Near St. Louis private munificence has formed and opened to the public a botanic garden. The common of Boston is a piece of undulating ground of 48 acres, in most of which trees have been planted without method, and a great many walks laid out with no other purpose than to offer short cuts through it from every entrance in all directions. It has a few fine trees, and the Beacon street mall, a broad avenue walk by the side of one of its boundaries, has a unique though perfectly simple character. The old public grounds of Cambridge, New Haven, and other towns often exhibit the beauty and value which trees acquire with age, when planted with ever so little art. These grounds are matters of town pride, and are assumed to have great value to the communities which possess them; but they are inconveniently arranged, badly kept, and bear a similar relation to a well designed and well kept park, that a wigwam does to a well appointed mansion. Savannah has a great number of small public squares, some few of them laid out and planted with taste, but most of them mere untidy spaces, too small for a walk or any purpose of recreation, except playing a game of marbles, and which apparently serve no purpose but to increase the distances between the houses of the town and enlarge its geographical size. At the Bonaventura cemetery, near Savannah, a natural assemblage of old live oaks, hung with moss, forms one of the finest scenes of druidic beauty in the world.—Landscape gardening in the United States has hitherto been chiefly directed to the improvement of naturally wooded scenery, and that on a small scale, yet in many instances, of which the best are on the banks of the Hudson, with admirable results. Publicly the art has been chiefly directed, also, to the improvement of naturally wooded, picturesque scenery in the formation of rural cemeteries. The motive of economizing space for graves, the association of funeral solemnity with shade, gloom, and seclusion, and the custom of yielding the plant-

ing of each allotment of ground for a family to the caprice or confined local purpose of its purchaser, have in these cases rendered the application of true art scarcely possible. Yet, though our rural cemeteries invariably contain much that is hideous, particularly in iron and marble, and are entirely without breadth or repose of scenery, many of them are very beautiful; and the older ones especially, although yet in their youth of the best tree life, exhibit the wealth of the country in elements for landscape art. The rural cemetery, which should, above all things, be a place of rest, silence, seclusion, and peace, is too often now made a place not only of the grossest ostentation of the living, but a constant resort of mere pleasure seekers, travellers, promenaders, and loungers; and this indicates, as much as any thing else, the need that exists in every town and village for a proper pleasure ground.—The most notable pleasure grounds of remote antiquity of which we have any clear account, were those formed by Nebuchadnezzar, at Babylon, to satisfy the longing for picturesque scenery of his home-sick Median bride. If we credit the accounts of Diodorus and Strabo, nothing has been attempted in modern times to compare in magnificence with what was there achieved. The ancient Persian gardens seem to have been designed with the same motives which rule in those of modern Turkey. The intention in these is to secure a luxurious repose, which is to be accomplished by establishing a sense of security and privacy; hence "the wall about" is an important feature, and is not hidden from view. Trees are planted in rows, in order that the wind may draw in currents between them. Small fountains of water or streams of running water, to increase the sensation and association of coolness, are required. Flowers are cultivated for perfume and beauty. Inducements to exercise are not desired. Distant views, which would be calculated to distract the mind from the present enjoyments, are not sought for. The proprietor commonly proceeds on entering his garden immediately to a seat near its centre, where he remains until he is ready to leave. Enclosures were sometimes made by the Persians for keeping wild beasts, and aviaries were common. Terebinthinate evergreens were esteemed a luxury.—The Greeks derived their ideal of gardens from the Persians, and seldom attempted any essential improvements upon it; which leads Lord Bacon to remark that "men came to build stately sooner than garden finely, as if gardening were the greater perfection." Athens had its public park, however, called *Academia*, which in the height of its civilization seems to have wanted nothing that we should deem essential for the purpose, considering the climate and the different customs of the people. Originally a rugged piece of ground, it was laid out by Cimon, who formed pleasant walks, introduced a stream of water, and planted groves. Facilities were designedly

offered for robust exercises as well as for contemplative recreation. At the entrance the first altar, dedicated to Love, was placed. Scattered through the grounds were statues and monuments to the most worthy citizens. The best evidences of Athenian civilization are connected with this park.—When Rome was in her glory, her citizens were proud of their country houses and pleasure grounds. The sites for these were chosen with the greatest care, and shaped elaborately in stately terraces about the mansion. The grounds were profusely furnished. Pliny's Tusculan villa was provided with a court for chariot exercise, and another for horseback riding; with terrace walks suitable for the general assemblage of his guests, and retired paths for those disposed for solitude. In the grounds were an enclosure for wild animals, an apiary, a snailery, and a dormice house. There was also a flower garden, with fountains flowing from marble vases. Adjoining the house proper, the park was strictly formal and symmetrical with the architecture; the walks were lined with box and plane trees sheared to the shape of walls, and in some parts trained in fantastic figures. These have been generally considered as mere puerile conceits, but no one who has thoroughly felt the peculiar charm of Italian landscapes, can fail to comprehend how they may have been used to add to the enchantment of the view of which they furnished the foreground; and it is to be remarked that Pliny describes at length how his seats and windows, even his bath and place of rest, were arranged with express reference to the best distant views over the Campagna. It is then probable that the shearing of his trees was intended to make them subordinate to the highest beauty of the natural scenery beyond his own possessions. This must be assumed, or we are left to suppose that a style of landscape improvement which was the foundation of all essays in rural art in Europe till the earlier part of the last century, and which had its origin in the golden age of Roman architecture and in the closest connection with it, was itself without any basis of art. We have no need to trace its lapses and revivals, its advances and degradations. As practised in England, at least, it had long lost the slightest element of the artistic feeling, which still in Italy it cannot be denied to possess. This is shown in the opinion of Sir William Temple that the best example of gardening at home or abroad was that at Moor Park, a garden which, according to Walpole, would have lost none of its beauty if designed by one "who had never stirred out of Holborn"—in other words, if utterly dis severed from all sentiment of nature. The real artistic qualities of the ancient style were thus entirely overlooked, and its mere excrescences and frivolities had come to be considered its essential features. In Addison's ridicule of these ("Spectator," No. 414), and in his praise of a shrubby which Bridgman, the

court gardener, had formed out of some old gravel pits in the palace grounds at Kensington, the first evidence of the practical revival of art in gardening is found. It is supposed that the earliest innovations upon the fashionable style were suggested by travellers' descriptions of the somewhat grotesque imitations of nature which for centuries had been the delight of the Chinese in their gardens. They were made very cautiously, usually as a mere incident of nature within a formal garden. Years after Addison's paper in the "Spectator" appeared, it was considered a bold eccentricity which carried the Serpentine through a corner of Kensington gardens with shores aligning with nothing in their vicinity. The first garden in which formality was attempted to be laid aside, and the intricacy of nature aimed at, is believed to have been that of Pope at Twickenham. Addison's garden, laid out also in defiance of the fashion by himself, and still existing near Rugby, is informal without being picturesque. The first man to attempt to form really a landscape in England was Kent, who had been a student of art in Italy, and who on his return was recommended by Lord Burlington to paint the ceilings at Stowe, and afterward as an architect, in which capacity he first gave his attention, as all architects should, to the connection of his buildings with the landscapes of their vicinity. Naturally enough, seizing in his design upon that which was most important, he swept away the rubbish which now represented the ancient style, and undertook the creation of scenery upon the ground at his command on the same principles that he would select a subject in nature for his canvas. The new style soon became the fashion, but like all fashions it was too generally adopted with little appreciation of the real basis it had in art. To avoid "three trees in a line," to form meaningless slopes, tame rivers, and monotonous groves, was not a difficult task even to the old gardeners, whose box Venuses and hornbeam hedgehogs had become dead stock. A host of servile followers after Kent supplied the demand for change which rapidly extended to almost every country seat of importance in the kingdom; and, in their haste to demonstrate the landscape capabilities of the ground which they were called to improve, too often the destruction of noble avenues and terraces was involved, the value of which when rightly placed had probably been disregarded by Kent merely out of disgust with their general misplacement. In the latter part of the 18th century landscape gardening, in the hands of most of its professors, had thus well nigh again become a mechanical business, instead of the liberal art which Kent had made it. The ground was made to suit a plan the features of which were constantly repeated, instead of a plan being made to meet the suggestions of the ground. "Most of our large gardens," says a writer of the day, "are laid out by some general undertaker [contractor], who introduces the same

objects at the same distances in all." Thus, except where proprietors became artists themselves, talent was not demanded nor sustained, and the monotonous repetitions, the dulness, and the common marks of the respectability of fashion characterized nearly all the gardening of the time, until poetic and artistic genius again combined to criticize and create, as in the time of Pope, Addison, and Kent. In the various "Picturesque Tours" of Gilpin, and the voluminous "Essays on the Picturesque" by Sir Uvedale Price, the true principles of art applicable to the creation of scenery were laboriously studied and carefully defined. Shennstone, Mason, and Knight, by their poems, materially aided the revivification of the art. In more recent times the good service of Repton, London, Paxton, Kemp, our own Downing, and other artists and writers on the subject during the present century, merits warm acknowledgment. Downing's works especially should be in every village school library.—The natural style had soon after its adoption in England become fashionable on the continent, and writers there treating of it had even exercised some influence on the improvement of taste in England. An artistic sense is more generally perceptible in the detail of grounds on the continent than in those of England itself. In all close scenery, as well as in vistas, peeps, and what a landscape painter would consider "good bits" for sketches, the continental gardeners are often faultless; but the formation of entirely artificial complete landscapes, or the improvement of broad scenes throughout their whole scope and to remote distances, all in imitation of nature, is to this day the peculiar art of England.

PARK, EDWARDS A., D.D., an American clergyman, born in Providence, R. I., Dec. 29, 1808. He was graduated at Brown university in 1826, and at Andover theological seminary in 1831, when he was ordained pastor of the Congregational church in Braintree, Mass. In May, 1835, he became professor of moral and intellectual philosophy in Amherst college; in Sept. 1836, Bartlett professor of sacred rhetoric in Andover theological seminary; and since 1847 he has been the Abbot professor of Christian theology in the latter institution. He has contributed extensively to periodical literature, and has been one of the editors of the "Bibliotheca Sacra" from the beginning. He translated with Prof. B. B. Edwards a volume of "German Selections" (1839); and has edited the "Writings of Rev. William Bradford Homer," with a memoir (1842); a volume on homiletics called "The Preacher and Pastor," with an introductory essay (1845); the "Writings of Prof. B. B. Edwards," with a memoir (2 vols., 1853); and with Drs. Phelps and Lowell Mason the "Sabbath Hymn Book" (1858). In 1859 he assisted in editing a volume of "Discourses and Treatises on the Atonement," for which he wrote an introductory treatise on "The Rise of the Edwardean

Theory of the Atonement." In 1861, with Dr. Phelps and the Rev. D. L. Furber, he published a critical volume on hymnology, entitled "Hymns and Choirs." He has also published memoirs of Dr. Samuel Hopkins (1852), and Dr. Nathaniel Emmons (1861), prefixed to editions of their works; and various discourses, among which are a funeral sermon on Prof. Moses Stuart; a convention sermon on "The Theology of the Intellect and the Feelings," which was the theme of a prolonged controversy between him and the Rev. Dr. Hodge of Princeton; and a sermon at the dedication of the Broadway tabernacle in New York. He is generally acknowledged to be one of the foremost preachers of New England, and ablest living representatives of what is commonly called "the New England theology."

PARK, MUNGO, a Scottish traveller, born at Fowlshills, near Selkirk, Sept. 10, 1771, killed in Africa in 1806. He was one of 13 children of a Scottish farmer, but received a fair education, and at the age of 15 was bound apprentice to a surgeon in Selkirk. He afterward studied his profession at the university of Edinburgh, and soon after receiving his degree was appointed assistant surgeon to an East Indiaman, in which he made a voyage to Sumatra. On his return, learning that the African association were anxious to send an explorer to the river Niger, he offered his services, sailed from Portsmouth May 22, 1795, and in one month anchored at Jillifrey on the Gambia, whence he proceeded to the British factory of Pisania in the kingdom of Yan. During an illness of 5 months he acquired the Mandingo language, and on Dec. 2, accompanied by 6 negroes, set out on horseback toward the east. On reaching the border between Bondoo and Kajaaga, he found it necessary for his safety to travel by night; nevertheless at Joag in the latter kingdom he was robbed of half his goods. Unable on account of wars to traverse the country of Bambarra to Timbuctoo as he had intended, he resolved to make a detour toward the N. in hopes of reaching the same destination through the Moorish kingdom of Ludamar. It was here that Major Houghton had lost his life, and the inhabitants bore an exceedingly bad character for inhospitality and fanaticism. At Benown, the capital, a wild boar was let loose upon him, but, vastly to the surprise of the natives, it attacked the Moslems and let alone the Christian. He was then placed in a hut, in a corner of which the boar was tied, and it was debated between the king and his advisers whether he should lose his right hand, his eyes, or his life. At length, after more than a month's captivity and torture, he made his escape alone, and reached Bambarra, where he met with better treatment. On July 21, 1796, he struck the Joliba or Niger at Sego, a city of 4 distinct quarters, 2 on each side of the river. Communication was kept up by large canoes, which were constantly crossing and recrossing; and so great was the crowd of passengers that Park

had to wait 2 hours before there was room for him in the boat. Then, however, there came an order from the king forbidding him to cross, and he was indebted for relief to a woman who took him into her hut, gave him supper and a bed, and with the female part of her family sang a song about the "poor white man" which the traveller has preserved in his journal. "In the morning," he writes, "I presented my compassionate landlady with two of the four brass buttons which remained on my waistcoat, the only recompense I could make her." The king soon sent him a guide and a present of 5,000 cowries, with which he pursued his journey down the left bank of the river to Kea, where he dismissed the guide and went by water to Silla on the opposite bank. Here he was again attacked by sickness, and, worn down by disease, hunger, and fatigue, half naked, and destitute, he despaired of advancing further into a country where the fanatical Mohammedans were paramount, and at a season of the year when the tropical rains rendered travel impossible except by water. After collecting what information he could respecting the Niger and the adjacent country, he accordingly set out on his return, July 20, and after a long series of sufferings and robberies arrived at Pissania, June 10, 1797. An American vessel carried him to Antigua, whence he took ship for England, and on Dec. 22 landed at Falmouth. His unexpected return, after he had long been given up for dead, created an extraordinary enthusiasm. An outline of his adventures was drawn up by Mr. Bryan Edwards, accompanied with geographical illustrations by Major Rennel, and the whole narrative appeared in 1799. It was written in a pleasing style and became exceedingly popular, though it threw little light upon the problem of the direction of the Niger, which had been the chief object of his search. Park now returned to his father's farm in Scotland, married, and commenced the practice of medicine at Peebles. In 1805 he was requested by the African association to undertake a second journey to the Niger under the auspices of the British government. Being well supplied with money, he resolved to travel with an armed force to Sego, and there to build two boats and sail down the river. The king gave him the brevet rank of captain, and his companion and brother-in-law Mr. Anderson that of lieutenant. The other members of the expedition were Mr. Scott, draughtsman, an officer and 84 soldiers of the garrison of Goree, 2 sailors, and 4 artificers. They reached Pissania April 28, and, without waiting for the rainy season to be over, at once pushed into the interior, keeping considerably to the S. of Park's former route, and winding among the head streams of the Senegal and Gambia. They were not much molested by the negroes, but the climate proved a more deadly enemy, and when they came in sight of the Niger near Bammakoo 28 of the soldiers and 8 carpenters had died. With the remnant of his force Park

floated down to Sansanding in canoes, and there replenished his funds by the sale of some of his goods. There too he had the misfortune to lose Mr. Anderson; Scott had also died, and when a boat was prepared for resuming the voyage, Park's only companions were Lieut. Martyn and 8 soldiers, one of whom was deranged. About the middle of November they set out, having first sent back their guide Isaaco with a journal of their discoveries. In the following year rumors reached the British settlements of Mungo Park's death, but nothing was known of his fate until the governor of Senegal in 1810 despatched Isaaco into the interior to ascertain what had become of him. From a man at Sansanding who had accompanied the party from that place to Yaoori, Isaaco received a later journal, and learned that after passing Jennee, Timbuctoo, and Yaoori, and repelling several attacks of the natives, they reached at Bousa a narrow pass where the river flows between precipitous rocks. Here they were set upon by the soldiers of the king of Yaoori, with lances, arrows, and stones. Two negro slaves were killed in the canoe, and the white men jumping into the water were drowned in attempting to escape. At first this story was not generally believed in England; but Clapperton found full confirmation of it, and learned that Park's manuscripts were still in the king's possession, but he was unable to obtain them.

PARKER, a W. co. of Ind., bordered W. by the Wabash river, and drained by Sugar and Raccoon creeks; area, 440 sq. m.; pop. in 1860, 15,448. It has an undulating surface and a very fertile soil, with extensive beds of coal. The productions in 1850 were 1,195,656 bushels of Indian corn, 101,720 of wheat, 80,165 of oats, 60,748 lbs. of wool, and 5,548 tons of hay. There were 17 saw mills, 18 tanneries, 1 newspaper office, 14 churches, and 1,660 pupils attending public schools. Capital, Rockville.

PARKER, ISAAC, an American jurist, born in Boston, June 17, 1768, died there, May 26, 1880. He was graduated at Harvard college in 1786, and removing to Maine, commenced the practice of the law in Castine. In 1797 he was elected by the federal party a member of congress, and upon retiring from office in 1799 he received from President Adams the appointment of marshal for the district of Maine, which he held until the accession of President Jefferson. He subsequently established himself in Portland, and in 1806 was appointed a judge of the supreme court of Massachusetts. In 1814 he succeeded Chief Justice Sewall as the presiding justice of the court, the duties of which office he discharged until the close of his life. He was also Royall professor of law in the law school of Harvard university. In 1820 he presided over the Massachusetts convention for the revision of the constitution.

PARKER, MATTHEW, second Protestant archbishop of Canterbury, born in Norwich, Aug. 6, 1504, died May 17, 1575. He entered Corpus Christi college, Cambridge, in 1520, and

by 1527 had become so renowned for his attainments in theological learning, that Cardinal Wolsey offered him a professorship in his newly founded college at Oxford, which he refused. In 1538 he received a license to preach, and became chaplain to Anne Boleyn in 1534, dean of the college of Stoke Clare in 1535, chaplain to King Henry VIII. in 1537, master of Corpus Christi college in 1544, vice-chancellor of Cambridge university in 1545, and dean of Lincoln in 1552. Having married in 1547, he was deprived upon the accession of Queen Mary of his offices, as like many of the clergy he refused to part with his wife. During the reign of Mary, according to a MS. in Corpus Christi college: "He lurked secretly in those years within the house of one of his friends, leading a poor life, without any men's aid or succor; and yet so well contented with his lot, that in that pleasant rest and leisure for his studies, he would never, in respect of himself, have desired any other kind of life, the extreme fear of danger only excepted. And therein he lived as all good men then did. His wife he would not be divorced from, or put her away all this evil time (as he might, if he would, in those days, which so rigorously required it), being a woman very chaste and of a very virtuous behavior, behaving herself with all due reverence toward her husband." Part of this time he spent in translating the Psalms into English verse, and writing a treatise entitled "A Defence of Priests' Marriages." Upon the accession of Queen Elizabeth he was chosen archbishop of Canterbury, and on Dec. 17, 1559, consecrated in Lambeth chapel. He was now at the head of the Protestant interest, charged with the duty of completing the work of the reformation. He successfully combated a lingering affection in the mind of the queen for the use of images, filled all the vacant sees with men of decided Protestant opinions, and strove to render the rites and ceremonies of the church as uniform as possible. He was a munificent patron of learning, having founded several schools, and made many valuable presents to the colleges at Cambridge, beside establishing scholarships and fellowships. He was one of the first chosen to review the "Book of Common Prayer," and a revision of the "Bishops' Bible" was made in great part under his inspection. He published a Saxon homily on the sacraments, and caused to be printed the chronicles of Matthew of Westminster, Matthew Paris, and Thomas Walsingham, and Asser's "Life of King Alfred."

PARKER, NATHAN, an American clergyman, born in Reading, Mass., June 5, 1782, died in Portsmouth, N. H., Nov. 8, 1838. He was graduated at Harvard college in 1803, and studied theology under the direction of the Rev. Dr. Bancroft of Worcester. In 1805 he was appointed tutor in Bowdoin college, and was ordained pastor of the South church in Portsmouth on Sept. 14, 1808, which office he retained through life. In 1825 he received the

degree of D.D. from Bowdoin college. When the division of the Congregational body in New England into two parties was recognized, he took part as a professed Unitarian. During his life he published nothing except two or three occasional sermons. After his death a volume of his sermons was published, with a memoir by the Rev. Henry Ware, jr.

PARKER, THEODORE, an American clergyman and scholar, born in Lexington, Mass., Aug. 24, 1810, died in Florence, May 10, 1860. His ancestors were all farmers or mechanics, men of plain sense, and a practical turn, with a love for military affairs. John Parker, his grandfather, was a captain of militia just before the revolution, and commanded his company on Lexington green, on the morning of April 19, 1775. The "queens-arm" which he took from a British straggler, after the main body of the troops had pushed on to Concord, was preserved by his grandson, and left by will to the state of Massachusetts. Theodore learned to work on the farm which had been in his family for 150 years, and in the tool shop; for his father not only tilled the soil, but bored pumps, made and repaired wheels and carts, and could turn his hand to almost any job of carpentry. In the winter the son went to the district school. At the age of 17 he began to teach school in the winter months, and part of the money thus gained he laid out for the books requisite to prepare for an advanced class in Harvard college. He surprised his father one night (Aug. 28, 1830) with the announcement that he had been down to Cambridge and had entered the freshman class. But he remained at home, working on the farm, and studying far beyond the requirements of the college programme, compressing three years into one, and going down to Cambridge to submit to the regular examinations. In 1831 he was teaching a private class in Boston. Latin, Greek, Hebrew, German, French, Spanish, and metaphysics filled his leisure. In 1832 he took an empty carriage house at Watertown, assisted in flooring it and fitting it up with desks, and opened a private school with two scholars, one of whom was on charity; he soon had over 50, however. For their benefit, and for his class in the Sunday school, he wrote a history of the Jews, which still lies in manuscript. Here he remained two years, pursuing the study of languages and theology, in order to enter the middle class at the divinity school in Cambridge in 1834. Syriac, Arabic, Danish, and Swedish were here added to his list of languages; and Anglo-Saxon and modern Greek were commenced. He was one of the editors of the "Scriptural Interpreter," a magazine conducted by members of the school. During the autumn and winter of 1836 he preached in various pulpits of Massachusetts, and was settled at West Roxbury in June, 1837. Here he slowly formed views upon the authority and inspiration of the Bible which were not in harmony with the teachings of any New England

pulpit; and he was already the subject of criticism among his Unitarian brethren. But the difference did not become well defined and public till the ordination of Mr. Shackford at South Boston, May 19, 1841; on which occasion Mr. Parker preached a discourse on "The Transient and Permanent in Christianity," which set forth the distinction between the theological forms and the essential spirit of religion. The objectionable feature was the assumption of the humanity and natural inspiration of Christ; this was the commencement of a controversy, during which Mr. Parker developed his anti-supernaturalism in various writings and sermons. In the autumn of 1841 he delivered in Boston 5 lectures, which formed a volume entitled "A Discourse of Matters pertaining to Religion," published in the spring of 1842. He delivered 6 "Sermons for the Times" in Boston and elsewhere during the autumn and winter of 1842. Somewhat overworked and harassed by the position of antagonism in which his views had placed him, he went to Europe in Sept. 1843, and travelled in England, France, Italy, and Germany, till his return in the summer of 1844. The controversy was renewed on occasion of his exchanging pulpits with some of the more liberal Unitarian preachers; and to satisfy the interest of numerous friends in Boston, he began to preach at the Melodeon, Feb. 16, 1845, and was installed there over a newly organized parish, styled the twenty-eighth Congregational society, in the spring of 1846. Up to this time, beside the writings above mentioned, his more notable productions were articles in the "Dial" upon German literature, St. Bernard, Pharisaism, Strauss, review of the Hollis street council, and an article in the "Boston Quarterly Review" upon Palfrey's "Academical Lectures." He had also written articles for the "Christian Register" and the "Christian Examiner," and "Inquiries into the Origin of Writing," which is still unprinted. His translation of De Wette's "Introduction to the Old Testament," upon which he had been laboring for some time previous to 1837, and to which he added original matter of his own, appeared in 1843, before his departure for Europe. Other translations, from Ammon, Eichhorn, and Gesenius, seem to have been preparatory to that important work. In Dec. 1847, appeared the first number of the "Massachusetts Quarterly," mainly under his editorial care, a review in politics and theology. - He conducted this during its life of 8 years, contributing many articles, the principal of which are: "R.W. Emerson," "Dr. William E. Channing," "Mr. Prescott as a Historian," and "The Political Destination of America." Though his labors as a preacher were very great, he engaged actively in lecturing, and travelled east and west, never without a carpet bag full of books, which he studied in the railroad cars. The invitations to lecture in every part of the North became at length so numerous that to save trouble he

used printed circulars of refusal. He vigorously opposed the Mexican war, and was one of the earliest advocates of temperance and anti-slavery, writing and speaking much for the latter cause especially. After the passage of the fugitive slave law in 1850, he became widely known, by speech and act, as its uncompromising opponent. Every case of attempted rendition in Boston enlisted his personal activity; and his sympathy was so prominent at the time of the rendition of Anthony Burns (May 24 to June 8, 1854), as to procure his indictment in the U. S. circuit court for resisting an officer of the United States in his attempt to execute process. This was based upon a speech which he delivered at Faneuil hall before an anti-rendition meeting, in which he was misunderstood to advocate a forcible rescue of Anthony Burns. The indictment was quashed by a decision based upon a technicality; but Mr. Parker had prepared an elaborate defence, which he printed. In Nov. 1852, his congregation occupied for the first time the great music hall in Boston, which was crowded every Sunday, the large congregation being reinforced by strangers from every part of the country, attracted by his fame. He was now often ill, and compelled for a while to cease preaching and writing; but his persistent will carried him through till Jan. 1859, when an attack of bleeding at the lungs brought to a close his public services at the music hall. On Feb. 8 he sailed for Santa Cruz, whence in May he sent a letter to his parish entitled "Theodore Parker's Experience as a Minister." From that island he sailed to Europe, spent some time in Switzerland, and went to Rome, where he passed the winter of 1859. Setting out thence in April, 1860, very much enfeebled, he reached Florence with difficulty, where he died. He was buried in the cemetery outside the walls; a stone, bearing simply the dates of his birth and decease, marks the spot.—A statement or scheme of his theology may be drawn up as follows. God is infinitely wise and good, impersonal because not comprehensible in any human conception, but personal because containing all his attributes in a unity of will and essence. He is immortal in nature and man through premeditated laws natural and spiritual, working in love and never in wrath, comprising all evil in the good of his ulterior designs, yet inspiring man with a moral sense and urging him to embrace goodness. The sentiment of religion belongs by creation to every human soul, who is receptive of religious and moral truth by direct nourishment from God according to the quantity of being and the quantity of obedience. Every kind of truth, all art and science, are necessarily nourished by an immanent God, and an intuitive ability everywhere holds the developing finite to the perfect and unchangeable infinite. The Bible contains various phases of the moral and religious growth of the human race, colored like other histories with the misconceptions of

half educated people, and with their love for the marvellous, and to be read and criticized on the natural ground of other histories. The absolute religion of which the human soul is made capable was perfectly set forth in Jesus, but mixed with local elements of time and race. The absolutely intuitive in man can recognize the absolute truths of the intuitions of Jesus, who was like all men directly inspired by the Father, and can separate them from the mistakes of the time and the traditions which gradually clothed them in a supernatural dress. A miracle is not an *a priori* impossibility, because God has infinite power; but the account of one is a subject for criticism, and depends upon evidence. The evidence for the miracles of the Old and New Testaments, for other miracles in ancient and mediæval history, and for those of modern spiritualism, is very defective; and if they could all be substantiated, no vital connection could be detected between them and spiritual truths, which come by intuition and appeal directly to the same. The truths of religion, in coming through this intuitive ability, are compelled to take the investiture which the mind can furnish. Ignorance smothered and dislocates the ray. Different races give the truth different expressions. Knowledge and culture simplify the theological statements of spiritual things, and man tends to put the transitory aside for the sake of the eternal, to reject doctrines concerning God and human nature which reflect his own passions and cramp his own spiritual liberty. He then sees that the truth of which he is capable would become superior to moral infirmity as well as to defective mental expression, and would enlist his will to uphold the absolute simplicity of the moral law, to make him love purity, peace, and charity, to abhor slavery, and to take pity upon all the unfortunate. The true church is a paternal coöperation of all believers in man's capacity for holiness and his equality of rights, to do the will of God on earth, and to organize in practical effect the great principle of love to God and to man.—Mr. Parker's printed works are: "Miscellaneous Writings" (12mo., Boston, 1843); "A Discourse of Matters pertaining to Religion" (1849); "Occasional Sermons and Speeches" (2 vols. 12mo., 1852); "Ten Sermons on Religion" (1853); "Sermons on Theism, Atheism, and the Popular Theology" (1858); "Additional Speeches, Addresses," &c. (2 vols. 12mo., 1855); "Trial of Theodore Parker, for the Misdemeanor of a Speech in Faneuil Hall against Kidnapping" (1855); "Two Christmas Celebrations;" and "Experience as a Minister" (1859). In addition to these, the work to which he devoted all the time he could procure, and which was intended to be an account of the development of religion through all nations, lies in a fragmentary condition. His library of more than 18,000 volumes he bequeathed to the free library of Boston.

PARKMAN, FRANCIS, an American author, born in Boston, Sept. 16, 1823. He was grad-

uated at Harvard college in 1844, visited Europe, and in 1846 made a journey across the prairies and explored the Rocky mountains. An account of this expedition was given in a series of articles in the "Knickerbocker Magazine," which were collected and published under the title of "The California and Oregon Trail" (New York, 1849). His next production was a "History of the Conspiracy of Pontiac, and the War of the North American Tribes against the English Colonies after the Conquest of Canada" (Boston, 1851). Mr. Parkman has been for several years engaged in writing a history of the French power in America, and has pursued his labors under the disadvantage of an affection of the eyes which renders him often wholly unable to read or write, and of a very painful disorder of the brain.

PARLATORE, FILIPPO, an Italian botanist, born in Palermo, Aug. 8, 1816. He received a medical education at the university of Palermo, was admitted to practice in 1834, and in 1837 published a treatise on the cholera. Leaving Sicily in 1840, he made an extensive tour of Italy and Switzerland, and published in Paris several botanical works, including his *Planta Novæ* and "Observations on some new Plants of Italy." In 1841 he read important memoirs on organography, vegetable morphology, and other botanical subjects previously neglected by Italian naturalists, before a scientific congress at Florence, and by his efforts succeeded in procuring the establishment in that city of a herbarium of all known plants, of which, at the recommendation of Humboldt, he was appointed the curator. At the same time a professorship of botany which had been for many years unfilled was revived for his benefit. In 1848 he published at Florence his "Comparative Botany," and soon after "Researches on the Structure of Aquatic Plants." Subsequently he undertook a scientific tour in northern Europe, penetrating as far as Lapland, where he made careful observations of the limits of vegetation, as he had previously done on the mountain ranges of central and southern Europe. His "Journey to the Great Saint Bernard" (Florence, 1849), and "Journey to the North of Europe" (1854), giving the results of these explorations, are preliminary to a comprehensive work on the botanical geography of the globe, on which he has for years been engaged.

PARLIAMENT (low Lat. *parlamentum*; Fr. *parlement*, from *parler*, "to speak"), originally a meeting or assembly for conference or deliberation; afterward applied in France to the principal judicial courts, and in England to the legislature of the kingdom. The word, or one very like it, was long in use in France, and was first applied there to general assemblies in the time of Louis VII., about the middle of the 12th century. The earliest mention of the word in the statutes of England occurs in the preamble to the statute of Westminster, 1272. Many writers have asserted the identity of the modern parliament with the general councils of the Saxons,

with their *michel-gemots* or great meeting, or their *witena-gemots* or meeting of the wise men; and also with the *commune concilium* and *magnum concilium* of later times. It is indeed indisputable, as Blackstone says, that general councils are coeval with the kingdom itself; but that those of early times bore any essential resemblance to the present parliament is far from certain. Particularly, it has been observed by intelligent authority, has antiquarian research failed to find in the general assemblies of elder times the royal summoning; the hereditary principle of the upper house, and the representative principle of the lower, which are the characteristic features of the British parliament as it now exists. But we may probably with safety assume that the present constitution of parliament existed early in the 14th century. In Magna Charta, King John promises to summon all archbishops, bishops, abbots, earls, and greater barons personally, and all other tenants in chief under the crown by the sheriffs and bailiffs; and there are still extant writs of the date of 1266, summoning "knights, citizens, and burgesses" to parliament. A statute passed in the reign of Edward II. (1322) declares that certain matters shall be established in parliament "by the king and by the assent of the prelates, earls, barons, and the commonalty of the realm, as has before been accustomed;" and it is of this statute that Mr. Hallam remarks, that it not only establishes the present structure of parliament, but recognizes it as already standing upon a custom of some length of time.—The imperial parliament of the United Kingdom of Great Britain and Ireland is composed of the crown and the three estates of the realm, the lords spiritual, the lords temporal, and the commons. It is the prerogative of the crown to convoke, continue, or dissolve it. Formerly it was the theory of the English constitutional law, that the power of the crown in these respects was measured only by its pleasure; that the sovereign might omit during his whole reign to call a parliament; or if he called one, might keep it undissolved for the same period. But now, on the authority of statute and otherwise, it is established that no parliament can last longer than 7 years; and that writs for summoning a new parliament shall issue within 8 years from the dissolution of the last one. In practice, parliaments assemble annually, and must continue to do so, while the legislation for the army, the judiciary, and the whole service of the kingdom has validity and makes appropriations for only a twelvemonth. Among the other constitutional prerogatives of the crown, as a branch of parliament, are its negative upon the choice of a speaker by the commons, and upon bills passed by both houses. But neither of these prerogatives could now with safety be arbitrarily asserted by the sovereign.—The house of lords possesses peculiar and exclusive judicial authority, both in law and in equity, as the final court of appeals and errors, upon

writs from all the higher courts of record in the country. (See LORDS, HOUSE OF.) The lowest branch of parliament, the third estate in dignity, but in fact the foremost in substantial power, is the commons; or, to use the title which suggests the composition of this house, the knights, citizens, and burgesses. The rise and increase of the power of the commons offers a subject of most interesting study. Into historical details, however, we can enter here no further than to note those epochs which more immediately explain the constitution of this branch. We have seen that the first clear intimation of two branches of parliament (not then necessarily sitting separate, however) is afforded by Magna Charta. The great charter provides a mode of summons according to rank. The greater barons were to be individually cited by special writs, while the other tenants *in capite* were to be called by general summons. That is to say, with regard to the former of these classes an individual and absolute right seems to be conceded; while with regard to the latter, those were considered to be entitled and summoned whom the general body should select as their representatives. Thus these inferior landed proprietors, or lesser barons as they have been called, ceasing gradually to be regarded as peers, were allowed and sometimes directed to be summoned as knights of shires. Gradually, too, their privilege diminished, till they lost altogether the right of sitting with their superiors; and, merging in the commonalty, they came in time to form with the representatives of cities and boroughs the lower house. The union of these three classes in one assembly is probably rightly fixed at the close of the 18th century. During the reigns of the first three Edwards, the power of the commons was materially enlarged, and firmly established; and to the time of Edward IV. Mr. Hallam refers the foundation of the principle, that the assent of the two houses is necessary to every legislative act. But owing to the jealousy of the upper house, and to its opportunities for defeating the rights of the commons, the principle was for a long time not carried out. In the reign of Henry VI. it first became true in fact, as it had long been in the theory of the government, that "the law of the land is made in parliament by the king and the lords spiritual and temporal and all the commonalty of the realm."—It is the exclusive right of the commons to originate all bills which either directly or by construction impose any burden or charge on the people; and these bills include not only those which provide supplies for the general administration of the government, but also all those which contemplate a tax upon the public for any purpose or in any mode. Hence, all bills for making roads and canals or building bridges, paving and building acts, and any others which propose the collection of tolls or the imposition of rates or duties upon the subject, must originate in the commons. All other bills of whatever nature may

originate in either house indifferently. In practice, each house appropriates to itself peculiar cognizance of those matters of which, from its experience and constitution, it is the most competent judge. Bills, for example, which concern the settlement of peerages begin naturally with the lords; while bills for regulating elections originate as naturally with the commons. The commons have not final appellate jurisdiction like the lords; yet in certain cases they exercise judicial functions, and when proceeding in such cases they are a court of record, and their journals bear the credit of public records. Examples of these functions are the consideration of cases of contested elections and returns, and the hearing and punishing of contempts. Acting in concurrence with the lords, they exercise higher powers of judicature, as in matters of attainder and pardon, and until lately of divorce. The house of commons consists at present of 654 members. Of these England and Wales send from counties 159, from the universities 4, and from the towns 333. Of the Scottish members, 30 come from counties and 23 from towns. Ireland returns 64 members for counties, 39 for towns, and 2 for the university of Dublin. The religious disqualifications which formerly excluded some persons from parliament were removed, partly by the repeal of the test act in 1828, and partly by the Catholic emancipation act of 1829. Until 1858 Jews were shut out from both houses of parliament by that clause, to which they could not conform, which required the oaths to be taken "on the true faith of a Christian." This disabling clause has not been stricken from the formulas of the oaths, but in the year just named a statute was passed which permits either house to dispense with it at its pleasure, in the administration of them. No peer of parliament is eligible to the commons; yet any Irish peer, not of the number of the 28 representatives, may sit in the lower house. This rule is however not true of the same class of Scottish peers. No person officially employed about duties or taxes created since 1692 (except commissioners of the treasury), no officer of excise, customs, stamps, &c., no pensioner of the crown, no contractor with government, no judge of the king's bench, common pleas, or exchequer, no chancellor or vice-chancellor (it is otherwise with the master of the rolls), and no police justice of London is eligible; and by statute 6 Anne, c. 27, it is provided that no person holding any new office under the crown created since 1705 is eligible. But if any member of the house of commons accept any office of profit under the crown while he is a member, his seat becomes vacant, but he may be again elected. The house of commons has given various constructions of this statute, and expressly excepted from it a large number of offices. The clergy of the church of England and Ireland are ineligible. Sheriffs of counties, mayors, and bailiffs of boroughs, as returning officers, are also inca-

pacitated. Ministers of the crown, however, are required to hold seats in one house or the other; and members of the lower house, on receiving a cabinet appointment, resign their seats and appeal to their constituents for reelection, as an indication of confidence in the ministry.—Until it was remodelled 80 years ago by the reform act, the parliamentary franchise remained as it had been fixed by statutes of the time of Henry VI. It had been narrowly restricted by these statutes, both in the counties and in the boroughs, and the necessity of a thorough change had long been insisted on. The tory ministry of the duke of Wellington in 1830 was brought to an end by the determined opposition of the premier to any change in the representation and suffrage, and was succeeded by a ministry headed by Earl Grey, who had been the steady advocate of parliamentary reform for 40 years, and who then stood at the head of the whig aristocracy. The first reform bill was introduced into the house of commons, March 1, 1831, by Lord John Russell, and was carried on the 2d reading after great debates, by a vote of 302 to 301. Subsequently ministers were defeated on several questions, and parliament was dissolved, April 23. The new house of commons was chosen under great popular excitement, and in a full house the ministerial majority was about 130. Another reform bill was brought forward, and after a discussion of many weeks was passed, 345 to 236. The house of lords threw out the bill by 41 majority. This caused great indignation. Immense popular meetings were held, and there were riots at Derby, Nottingham, and Bristol, that at Bristol being of an alarming character. On Dec. 12 a 3d reform bill was brought forward, which passed to a 2d reading by 162 majority. The lords passed it to a 2d reading by 9 majority, April 14, 1832; but on May 7, in committee, they defeated the ministry by a majority of 35. The court, from the queen downward, was almost entirely opposed to reform, and the king's mind had been acted on by most persons who surrounded him adversely to the popular cause. He had been averse to the creation of peers, and it was understood that the peers should allow the bill to pass. This understanding having been departed from, the ministry demanded a creation of peers from the king. He refused, and they resigned. Wellington undertook to form a government, but the house of commons set itself in resolute opposition to the duke, and advised the king to create as many peers as should be necessary to carry the bill through the upper house. On May 15 the whigs announced their return to power, and in June the lords passed the reform bill. This bill gave 159 members to the counties, the constituencies being 82, whereas they had before been but 59, returning 94 members. Fifty-six boroughs that had returned 111 members were extinguished; 80 others lost one member each; and 2 united boroughs that had sent 4 members

were reduced to 2. As there was no reduction of the numbers of the lower house made, this left 148 members to be disposed of, 65 of whom were given to counties, 22 to the metropolitan districts and other boroughs with populations of 25,000 and upward, and 21 to boroughs having 12,000 inhabitants and upward. New and great constituencies were created in England and Wales. Numerous improvements in elections were provided. Inhabitation was made the basis of the borough franchise. Under certain regulations, occupants of houses of the yearly value of £10 became electors. The county franchise was extended to copyholders and leaseholders, and under some circumstances to occupiers to the value of 40s., thus destroying the monopoly of the freeholders, who were not allowed to vote for both county and borough. The Chandos clause—so called from its mover, the marquis of Chandos, eldest son of the duke of Buckingham—provided that tenants at will of the annual value of £50 should have the county franchise. This last provision, and the great extension of county representation, went far to justify the declaration attributed to Earl Grey and Lord Althorp, that the reform act was "the most aristocratic measure that ever passed the house of commons."—Scotland while an independent kingdom had a parliament, dating, it is supposed, from the 13th century, and very similar at first to that of England, but never like the English divided into two houses. It comprised the high ecclesiastics, the great nobles, and the representatives of the freeholders of the counties and of the citizens of the royal burghs, who all sat in one hall. The functions of a house of lords or higher house were performed in some degree by a committee called "the lords of the articles," consisting latterly of 32 members, who did all the work of parliament, the house doing scarcely more than to pass the acts proposed by the committee. The Scottish parliament was abolished by the legislative union of Scotland with England in 1707.—In Ireland a parliament was formed by the English settlers toward the end of the 13th century, but it was not till the reign of James I. that the whole island was represented. The Irish parliament, however, was held to be subordinate to that of England until 1783, when its exclusive authority in matters of legislation and judicature for Ireland was formally admitted. Its brief independence however, and its existence, terminated in 1800 by the union of Ireland with Great Britain.—The French parliaments were supreme courts of law, and were established at successive periods in the principal cities of the kingdom. The most ancient and important of these bodies was the parliament of Paris, the foundation of which is ascribed to Louis VII. about the middle of the 12th century. It was at first a court of justice which accompanied the king wherever he went, till Philip the Fair fixed it at Paris by an ordinance dated March 23, 1302. The other parliaments of France were institut-

ed in the following order: Toulouse, 1302; Grenoble, 1451; Bordeaux, 1462; Dijon, 1477; Aix, 1501; Rouen, 1499 and 1515; Rennes, 1553; Pau, 1620; Metz, 1633; Besançon (at first at Dole), 1676; Douay (at first at Tournay), 1713. The chief officers of these bodies were a first president and 9 presidents *à mortier*, as they were called from the shape of their caps. The parliaments received appeals from the lower tribunals, and had jurisdiction over causes relating to peers, bishops, seneschals, chapters, communities, and bailiwicks; and they registered the laws, edicts, and ordinances promulgated by the king. The members of these courts were at first appointed by the crown. Francis I. introduced the practice of selling seats in them, and they continued thenceforth to be objects of purchase. The parliament of Paris, which was at first merely judicial in its functions, gradually assumed a considerable degree of political power. It frequently refused to register laws which it did not approve, and held spirited contests with the crown on some occasions. The king, however, had the right to compel it to register his decrees by appearing in person in the court and giving the order to register, a proceeding which, from some of the attendant forms, was called holding a bed of justice. The parliament of Paris played an important part in the troubles of the Fronde at the beginning of the reign of Louis XIV., and also in the latter part of the reign of his successor. It was finally suppressed, with all the other parliaments of France, by a decree of the constituent assembly, Sept. 7, 1790.

PARMA, *Ducry* or, a province of N. Italy, formerly an independent state with absolute hereditary sovereigns, but annexed to the kingdom of Sardinia in 1860, lying between lat. 44° 19' and 45° 8' N. and long. 9° 23' and 10° 40' E., bounded N. by Lombardy, from which it is divided by the Po, E. by the duchy of Modena, S. by Carrara and the province of Genoa, and W. by the provinces of Genoa and Alessandria; length from E. to W. about 50 m., breadth from 40 to 50 m.; area, 2,401 sq. m.; pop. in 1857, 499,885. Its S. frontier extends to the Apennines, whence the country slopes N. to the banks of the Po, and thus belongs to the extensive valley of that river. It is intersected by several offsets of the Apennines, presenting bleak and rugged summits, some of which exceed 6,000 feet in height, and whose sides are covered with forests of chestnut, oak, ash, and beech. The Tidone, Trebbia, Nura, Taro, Parma, and other streams, none of which are navigable, flow toward the Po, watering the lower regions, which are fertile. The mountainous districts afford their inhabitants but a scanty supply of food; and many consequently leave their homes in summer to seek employment. The pasture lands are extensive, and excellent cattle and sheep are raised. Cheese is produced in abundance, and is in high repute. Swine, fed upon the acorns in the forests along the banks of the Po, are of fine quality. Silk is

produced in comparatively small quantities, but the silk manufacture is the principal branch of industry in most of the towns. The mineral wealth of the country consists chiefly of salt springs, which yield annually upward of 12,300 owt. of salt. Iron is worked to some extent; there is one copper mine, and marble, alabaster, crystals, and lithographic stones are obtained. The facilities of communication are few, the Po being in fact the only thoroughfare. There are few highways; the roads are indifferent, and there are no canals except for irrigation.—The annexation of the duchy to Sardinia has not materially altered its administrative organization. It is divided into 5 provinces, each under a governor or a prefect, viz.: Parma, Val di Taro, Piacenza, Borgo San Donino, and Lunigiana. A supreme court of justice sits at Parma and a court of appeals at Piacenza; 88 inferior courts are distributed among the other towns and villages. The code promulgated in 1820 was based upon the *Code Napoléon*. The Roman Catholic is the established religion, but other creeds are tolerated. The duchy is divided into 3 bishoprics: Parma, Piacenza, and Borgo San Donino. Primary schools afford gratuitous instruction; collegiate or secondary schools are established in several towns, while Parma and Piacenza have each a superior academy. The military force of the late ducal government amounted to 4,075 men, which might be raised to over 6,000 in time of war. The public revenue amounted to 9,971,685 *lire*, and the expenditures to 9,536,900 (about \$475,000). The state property was about \$1,500,000, and the public debt \$335,000.—Under the Romans, who subdued it in 184 B. C., this territory formed part of Cisalpine Gaul. After the fall of the western empire, it was held successively by the Ostrogoths, the Longobards, and Charlemagne, who granted it to the pope. It became independent during the wars between the holy see and the German empire, and afterward passed under the dominion of several lords, until in 1346 it fell into the hands of the Viscontis of Milan. In 1511 the congress of Mantua restored it to Pope Julius II. After being for a while occupied by the French under Francis I., it was in 1545 bestowed by Pope Paul III. upon his natural son Pietro Luigi Farnese, whose successors held the duchies of Parma and Piacenza until 1781, when the male line became extinct. Elizabeth Farnese, the ambitious queen of Philip V. of Spain, now obtained the duchies for her son Don Carlos; but when he became king of the Two Sicilies they were annexed to Austria. The treaty of Aix la Chapelle in 1748 restored them to Philip, the 2d son of Elizabeth Farnese, who transmitted them to his son Ferdinand. In 1801, in consequence of secret treaties with Spain, they were incorporated with France and formed the department of the Taro. By the treaties of Paris and Vienna, the duchies of Parma, Piacenza, and Guastalla were bestowed upon Maria Louisa, the wife of Napoleon, who gov-

erned them till her death in 1847. Parma and Piacenza then devolved upon Charles Louis, duke of Lucca. This prince was expelled by the insurrection of 1848, and his dominions fell into the hands of the king of Sardinia; but the defeat of Charles Albert soon restored them to the house of Lucca. Charles III., to whom his father had resigned his crown, returned in 1849, but became very unpopular, and was assassinated March 27, 1854, by some unknown hand. His eldest son, Robert, was proclaimed duke, under the regency of his mother, Louise Marie Thérèse de Bourbon, sister of the count de Chambord. The administration of this princess gave some satisfaction; but on the outbreak of the war of 1859 she had to leave the country with her son. The annexation of the duchy to Sardinia, in accordance with a nearly unanimous vote of its citizens, was proclaimed by Victor Emanuel, March 18, 1860; but it has not yet (March, 1861) been recognized by any foreign power.—PARMA, the capital, is situated on both sides of the river Parma, 12 m. S. from the Po, and 72 m. S. W. from Milan; pop. in 1857, 43,664. It is of circular form, surrounded by walls and ditches, about 4 m. in circumference, flanked with bastions, and entered by 5 gates. The streets are tolerably well laid out, and the old Roman Via Æmilia, which forms the principal avenue, extends across the city in an E. and W. direction. There are 4 principal squares, one of which, the Piazza Grande, is remarkably handsome. The private houses are generally plain. The cathedral is a noble building, partly in the Romanesque style and partly Gothic. It was consecrated in 1106, but has since been several times repaired. It is built in the form of a Latin cross with an octagonal cupola in the centre, adorned with a magnificent fresco by Correggio representing the assumption of the Virgin. It also contains numerous paintings and statues of great merit. The baptistery in the vicinity is one of the finest in Italy; it has 8 sides externally and 16 internally, and is built of Verona marble and curiously ornamented with bass-reliefs. There are many other churches, some of which are beautifully adorned with works of art, and several nunneries and monasteries. The ducal or Farnese palace, an immense building, contains a picture gallery, a museum of antiquities, a library of 100,000 volumes, and a large theatre. Parma has an academy attended by about 400 pupils, the colleges of Maria Luigia and St. Orsola, an episcopal seminary, and several inferior schools. There is a hospital capable of accommodating 500 patients, foundling and lying-in hospitals, infant and lunatic asylums, and several other charitable institutions. The manufactures consist of silk, cotton, and woollen goods, carpets, lace, leather, fringe, paper, earthenware, hats, furniture, carriages, hardware, cutlery, glass, glue, musical instruments, and candles, and there are dye and saltpetre works. The trade includes some of the articles just enumerated, together with grain, wine, and provisions.

Parma was a Roman colony, but during the triumvirate it became almost depopulated, and being repeopled by Augustus it assumed the name of Colonia Julia Augusta.

PARMA, ALESSANDRO FARNESE, 8d duke of, an Italian soldier, born in 1546, died Dec. 8, 1592. He was the son of Duke Ottavio by Margaret, the natural daughter of the emperor Charles V., was educated by his mother, and enlisted in the service of Spain in early youth. He fought in the naval battle of Lepanto in 1571, and was sent in 1577 to the Netherlands, where in the following year he took part in the victory of Gembloux, won by Don John of Austria over the Dutch. He succeeded Don John as governor of the Low Countries, and forced the Belgian provinces into submission, successively taking Maestricht, Breda, Tournay, Dunkirk, Bruges, Ypres, Ghent, and Antwerp (1578-'83). On his father's death in 1586, he inherited the duchy, but did not even visit his dominions. In 1588 he was put in command of the armada which Philip II. of Spain sent against England; but being shut up with his army in Antwerp by the Dutch flotilla, he was only a spectator of its disastrous failure. In 1590 he invaded France at the head of the Spanish army, and relieved the rebellious city of Paris, which was then besieged by Henry IV. In 1592 he marched into Normandy, and obliged Biron to raise the siege of Rouen, one of the principal cities held by the league; but he received here a wound which afterward proved fatal. Being attacked by Henry IV., who hemmed in his army between the Seine and the English channel, he foiled the efforts of his opponent, and succeeded in landing his troops on the opposite bank of the river, when they returned to the Netherlands. As for himself, he was unable to proceed further than Arras, where he breathed his last. He was a man of consummate military and diplomatic genius. A bronze equestrian statue of him by John of Bologna adorns the principal public square at Piacenza. By his marriage with Mary of Portugal, he left a daughter and two sons, the eldest of whom, Ranzio, was his successor.

PARMENIDES, a Grecian philosopher, born in Elea in Italy about 518 B. C. He was held in such esteem there that the citizens every year bound their magistrates to obey the laws which he had enacted for them. He was the instructor of Empedocles and Zeno. He went to Athens at the age of 65, and Plato called him "the great," and Aristotle deemed him the chief of the Eleatics. His philosophical opinions (see ELEATIC SCHOOL) are embodied in a hexameter poem "On Nature," some fragments of which are extant, and have been published by Karsten in the *Philosophorum Græcorum Veterum Operum Reliquiæ* (Amsterdam, 1835).

PARMENIO, a Macedonian general, born about 400, killed in 380 B. C. He was the favorite of Philip of Macedon, who used to speak of him as the only general he had found.

He defeated the Illyrians in 356, upheld the Macedonian influence in Eubœa in 342, and in 336 was sent with an army into Asia. When Alexander invaded that region he was made second in command, and led the left wing at the battles of the Granicus, Issus, and Arbela. While the king was pursuing Darius in Parthia and Hyrcania, he completed the subjugation of Media; but in the mean time his son Philotas was accused in Drangiana of conspiring against Alexander's life, and when put to the torture made a confession which implicated his father. Alexander caused the veteran general to be assassinated, though there is little probability that he was guilty.

PARMIGIANO, or PARMIGIANINO, an Italian painter, whose real name was Francesco Mazzuoli, born in Parma, Jan. 11, 1508, died in Casal Maggiore, Aug. 24, 1540. In his 14th year he produced a picture of the "Baptism of Christ," exhibiting a remarkable grace of style. Four years later, while assisting Correggio in his labors in the church of San Giovanni in Parma, he cultivated the manner of that master; but he was in no respect his pupil, having too much ambition to become the imitator of any one. In his 20th year he repaired to Rome, where the poets of the day, in the warmth of their admiration, declared that the mantle of Raphael had fallen upon him. Clement VII., Cardinal Ippolito de' Medici, and others, employed him extensively; and for a noble lady, Signora Maria Buffalini, he painted his celebrated "Vision of St. Jerome," now in the British national gallery. It is related that during the sack of Rome by the constable de Bourbon, the painter was so absorbed in the execution of this picture as to have become indifferent to the scenes of rapine and violence enacting around him. A party of soldiers who surprised him in his studio, awed by the beauty of the mother and child, retired without doing him any injury. He was however soon after obliged to take refuge in Bologna, where his best works were produced. Among these were the *Madonna della rosa*, in the Dresden gallery; the *Madonna dell' collo lungo*, in the Pitti palace; and the famous altarpiece, now in the gallery at Bologna, called the *Santo Margherita*, which Guido preferred to the St. Cecilia of Raphael. In 1581 Parmigiano returned rich and celebrated to his native city, and was commissioned to execute a series of frescoes in the church of Sta. Maria della Staccata, which after a delay of several years he commenced, but never finished. Among the figures completed is a celebrated one of Moses breaking the tables of the law. His failure to execute these frescoes has been attributed to an indulgence in gambling and dissipation, and to a taste for alchemy. He was finally thrown into prison for neglecting to fulfil his contract; and having by fresh promises obtained his freedom, he escaped into the neighboring territory of Cremona, where he died a few months later.

PARNASSUS, in ancient geography, a mountain range of Greece which commences near Cæta and Corax, and, traversing Doris and Phocis in a S. E. direction, terminates at the Corinthian gulf. In a more restricted sense the name is applied only to the highest part of the range, which lies a few miles N. of Delphi in Phocia, and culminates in Mounts Tithorea (now Velitza) and Lycorea (now Liakura). Its sides are well wooded and abound in caverns and picturesque ravines. On the summit snow lies the greater part of the year. In antiquity it was celebrated for its sacred character. Delphi at its foot was the seat of a famous oracle of Apollo. The god himself and the Muses made the mountain their favorite haunt, and the latter held here their assemblies. The Castalian spring in which the Pythoness used to bathe sprang from a cleft in the rocks between two of the summits. The Corycian cave, sacred to Pan and the Muses, was on Mt. Lycorea. Parnassus was also sacred to Bacchus, and the theatre of the Bacchanalian revels of the Thyades.

PARNELL, SIR HENRY BROOKE. See CONGLETON.

PARNELL, THOMAS, D.D., an Irish clergyman and poet, born in Dublin in 1679, died in Chester in Oct. 1718. He was the son of a commonwealth's man who had settled in Ireland at the time of the restoration, was admitted to the college of Dublin at the age of 13, was graduated M.A. in 1700, took holy orders in the same year, and was created archdeacon of Clogher in 1705. He made frequent visits to England, staying in Ireland in fact no longer than was necessary to collect his revenues, or wear off in seclusion the fits of spleen to which he was frequently subject. With Pope, Swift, Arbuthnot, and Gay he was united in the closest friendship, and was a member of the famous Scriblerus club. He assisted Pope in his translation of Homer, and wrote the life of Homer prefixed to the Iliad, of which Pope says: "It cost me more pains in the correcting than the writing it would have done." His prose style in fact was stiff and incorrect, and his only considerable composition of this sort except the life of Homer was a satire on Dennis and Theobald, under the title of "A Life of Zoilus." At the instance of Swift, Archbishop King gave him a prebend in 1718, and in May, 1716, presented him to the vicarage of Finglass, in the diocese of Dublin. He was a man of delightful social qualities, but in the latter part of his life the victim of intemperance, to which he is said to have been led through grief at the death of his wife. A selection from his poems was published by Pope in 1722, and a supplementary volume, which added nothing to Parnell's reputation, appeared in 1758. The "Allegory on Man," "The Hermit," "A Fairy Tale, in the ancient English Style," "Hesiod, or the Rise of Women," and a translation of Homer's "Battle of the Frogs and Mice," may be men-

tioned as among his happiest productions. "His praise," says Dr. Johnson, "must be derived from the easy sweetness of his diction; in his verses there is more happiness than pains; he is sprightly without effort, and always delights though he never ravishes; every thing is proper, yet every thing seems casual." His life was written by Goldsmith.

PARNY, ÉVARISTE DÉSIRÉ DESFORGES, chevalier de, a French poet, born in St. Paul, island of Bourbon, Feb. 6, 1753, died near Paris, Dec. 5, 1814. He went to France to study with the ultimate purpose of entering the church, but soon changed his mind and became a soldier. In 1773, returning to his native island, he fell in love with a young creole lady, Esther de Baif, whom he afterward celebrated under the name of Éléonore. His father opposed the marriage, and the young officer repaired again to France, where he devoted himself to literature. In 1777 he published his *Voyage en Bourgogne*, a lively account of travel in prose and verse, and a semi-satirical poem, *Épître aux insurgents de Boston*. This was followed in 1778 by his first collection of erotic poems, which were republished with the addition of a 4th book, and procured him from Voltaire the surname of the "French Tibullus." In 1785 he went out to India as aide-de-camp to M. de Souillac, who had been appointed governor-general of the French possessions. Returning with despatches in the course of a few months, he retired to the village of Feuillancourt, near Paris, where he occupied his leisure hours with writing poems, among which were *Les fleurs*, *La journée champêtre*, and *Les douze tableaux*. In 1795 he was appointed to a subordinate office in the department of public instruction, and for one year held the post of administrator of the *théâtre des arts*, now the grand opera. His later poems, remarkable for their union of wit and obscenity, are not worth specifying, though they were in accordance with the depraved taste of the times. He was admitted to the French academy in 1803. Français de Nantes gave him an office in the administration of the *droits réunis*, and Napoleon bestowed upon him a pension of 3,000 francs. His complete works were published in Paris (5 vols. 18mo., 1808) and Brussels (2 vols. 8vo., 1826).

PARODY (Gr. *parodia*, a song sung beside, that is, with certain changes), a composition in verse or prose, designed to turn into ridicule a serious composition. It preserves the form and style, but either substitutes for the original an entirely different composition, or introduces changes applying it to some inappropriate subject, or alters some of the words and phrases in such a way as to convey a ludicrous sense. The Greeks are supposed to have been the inventors of parody, and the *Batrachomyomachia*, or "Battle of the Frogs and Mice," ascribed to Homer, has been regarded as the earliest example of this sort of composition. There is little doubt, however, that the *Batra-*

chomyomachia is of more recent date, and the origin of parody may with more probability be assigned to Archilochus.

PAROL (Norman Fr., a spoken word), as an adjective, in law, by word of mouth, not written. This word has an important meaning in the law of evidence, and also in the law of contracts. The general rule in evidence is, that a written instrument cannot be contradicted or varied by parol evidence, but may be explained. (See EVIDENCE.) In contracts the common law of England made a wide and strongly marked distinction between specialties and simple contracts. Specialties are either sealed instruments, all of which in law are deeds (see SEAL), or judgments of a court of record (see JUDGMENT), recognizances and statutes staple. Simple contracts are all those which are not contracts by specialty. By specialty contracts is commonly meant contracts under seal; by simple contracts are meant parol contracts, or contracts by word only, whether that be written or spoken. In a few instances a distinction has been taken between written and spoken contracts, confining the term parol to the latter; but it is well established, and now universally conceded, that an oral contract is the same thing in law as a written but unsealed contract, differing only as the above stated rule of evidence applies to the proof of it, or as there may be statutory provisions upon any special matter, requiring that contracts in relation to it should be in writing. (See FRAUDS, STATUTE OF.) It will be seen in the article SEAL that a very different system of law is applied to instruments which have seals affixed to them.

PAROLE, in military law, the promise of a prisoner not to escape, if he is allowed certain liberties. This is seldom or never sanctioned by an oath, but is a *parole d'honneur*; and it is always deemed an indelible disgrace if this word of honor is violated.—Parole, in military matters, also means the "word" or sign given out by the commander of a post, every day, which word being communicated to the guard, and to every one who has permission to go in or out, or, in military phrase, to pass the guard, serves to distinguish him. Wherefore every guard of such a place is ordered to prevent, by arrest, or if need be by death, the passing of his post by one who cannot or does not give the word for the day. Sometimes two words are given, one of which the guard utters, and the other is to be pronounced by one who would pass him. These are then called the sign and countersign. As a matter of convenience, similar arrangements are often made at the door of a room, or the entrance of any place, where persons are meeting for private purposes and wish to protect themselves from interlopers.

PAROPAMISAN MOUNTAINS, a range of mountains traversing Afghanistan and E. Persia, called sometimes the W. Hindoo Koosh or the Ghoor mountains. Beside their eastern connection with the Hindoo Koosh, they join on the west the Elbrooz mountains. From north

to south they are 200 m. in length, and from east to west 350, separating the desert of Yezd from that of Toorkistan. On the east the mountains are precipitous and the valleys narrow, but toward the west the elevations are lower and the valleys wider. In no place do they reach the limit of perpetual snow. These mountains are inhabited by various pastoral tribes. By the ancients they were called Paropamisus; but not being known until the time of Alexander, and then only imperfectly, their ideas in regard to them were exceedingly confused.

PAROQUET, or PARRAKEET, the common name of many old world parrots of the sub-family *pezoporina*. They all have a moderate bill, the tail long, broad, and more or less graduated, with the ends of the feathers narrowed, and the tarsi generally high and slender, and the claws nearly straight, enabling them to walk upon the ground more easily than the other sub-families. In the Australian genus *nymphicus* (Wagl.) the bill is strongly dentated, the wings and tail very long, the 2 middle feathers of the latter prolonged and pointed, and the tarsi stout. The crested paroquet (*N. Nova Hollandia*, Wagl.) is of an elegant form, though of a grayish color, with the sides and top of the head bright yellow, a reddish orange spot below the eye, and a handsome yellow crest like that of the lapwing; they are migratory, at times collecting in large flocks, and much upon the ground picking up seeds and grains; they breed in holes in gum trees in the neighborhood of water, the female depositing 5 or 6 eggs.—The broad-tailed paroquets (*platycercus*, Vig.), of Australia, New Zealand, and New Guinea, are very elegant, graceful, and lively birds, with diminished powers of flight and climbing and more activity upon the ground; the bill is short and curved, with obtuse tip and sides very slightly if at all dentated; the wings moderate, and the tail broad and long. They are usually seen in flocks upon the ground, in search of seeds, fruits, and grain, and sometimes do much damage both to the newly sown and ripening maize and wheat. The blue-cheeked paroquet (*P. pennantii*, Lath.) is beautifully colored with crimson, black, and blue, the first prevailing on the body and the last on the wings; it is very tame and familiar, and often destructive; great numbers are captured for the delicacy of the flesh; it is often kept in cages for its beauty, and is not unfrequently carried to Europe, but its powers of imitation are very small; the total length is about 16 inches, of which the tail is one half. The nonpareil paroquet (*P. eximius*, Shaw) is one of the handsomest of the family, having the head, neck, and breast scarlet, wings marzarine blue, throat and abdomen yellowish white, back undulated with blackish and yellowish green, and tail blue. More than 30 other species of this genus are described.—The ground paroquet (*pezoporus*, Illig.) is the most terrestrial of the family, as evinced by the

greater elongation of the tarsi and toes, the straighter claws, and the less depressed and more pointed tail. The *P. formosus* (Illig.) inhabits the bushy districts of Australia; it is about a foot long, of a lively green color, varied and barred with black and yellow; it lives entirely upon the ground, where it runs with great speed; it is very shy, and never takes to flight except for short distances; its flesh is highly esteemed as food; its eggs are laid on the ground.—Among the handsomest of the sub-family are the ringed paroquets (*palæornis*, Vig.), which have a short rounded bill, sharp-pointed, and the tail long and graduated, the 2 middle feathers longest; they are remarkable for the elegance of their form, their docility, and powers of imitation; most of the species are found in India and its archipelago, and may be known by the collar-like ring around the neck. The Alexandrine paroquet (*P. Alexandri*, Vig.) was so named from the supposition that it was the one brought to Europe by Alexander the Great; it is about 15 inches long, green above, paler or yellower below; across each shoulder is a purplish red patch; a black band from the lower mandible descends and passes backward so as almost to encircle the neck, growing narrowest behind, where there is a red collar becoming narrowest in front; the bill reddish. This bird was well known to the Greeks and Romans, who kept it in highly ornamented cages; it is mentioned by Aristotle and Pliny, and Ovid has described it in one of his most beautiful elegies (on the death of Corinna's parrot). A nearly allied species is the rose-ringed paroquet (*P. torquatus*, Vig.), 15 inches long, of which the tail is about 10, of a grass-green color with a rose-colored ring around the neck. There are about a dozen other species in India, associating in flocks, and often doing mischief to the crops; they are all docile, imitative, and handsome birds.—The grass paroquets (*melospittacus*, Gould) of Australia are remarkable not only for the beauty of their plumage but for their pleasing song; the bill is very short and high, the tail graduated and cuneiform, the tarsi long, and the toes slender. The warbling paroquet (*M. undulatus*, Gould) is about 7 inches long, with the upper parts oil-green with darker undulations, the lower parts yellowish green, as also the head and nape, the latter with fine, dark, undulating lines; an azure blue spot on each cheek; the tail green, the middle feathers tipped with azure, and a broad yellow band across it; the bill and legs gray. They pass most of their time on the ground, migrating with rapid flight from place to place in large flocks in search of grass and other seeds; during the heat of the day they remain concealed among the leaves of lofty trees; they are often kept in cages, where their beauty, song, and gentle and loving habits make them pleasing pets. In the allied genus *nanodes* (Vig. and Horsf.) or *euphema* (Wagl.), also Australian, are about half a dozen elegant

little grass paroquets, with habits like those of the preceding genus. One of the handsomest is the blue-banded paroquet (*N. venustus*, Vig. and Horsf.), about 9½ inches long, of which the tail is 4; the prevailing colors above are various tints of green, tinged in some parts with yellow and gray, the frontal band azure blue, the under parts below the breast rich yellow, the quills black margined with blue, and the tail blue and yellow. In the *N. pulchellus* (Vig. and Horsf.), the upper parts are green, the wings blue, the under parts and the outer tail feathers yellow.—The genus *trichoglossus* (Vig. and Horsf.), which seems to connect this sub-family with the lorises, hence called "lorikeets," takes the place in Australia of the Indian lorises, and contains some of the most beautiful of the parrot family; the prevailing color of the plumage is green, varied however with scarlet, blue, and yellow; the tail is elongated and graduated, and the wings narrow and pointed; the bill is slender and weak, but arched and hooked; the tarsi short and robust, and the strong and broad toes armed with sharp claws; the generic name is derived from the structure of the tongue, which has near the tip a pencil or brush of hair-like bristles, especially adapted for procuring the nectar of flowers, which forms their principal food; they also suck the juices of soft fruits, but do not attempt the hard seeds of which most parrots are fond. The blue-bellied paroquet (*T. multicolor*, Vig. and Horsf.) is about 13 inches long, of which the tail is 6; the head and throat are bluish purple, with a nuchal collar of bright green; breast vermilion red, passing on the sides into rich yellow; abdomen deep purple in the middle, vermilion tipped with green on the sides; under tail coverts red, yellow, and green, and under wing coverts red; upper parts grass-green, varied with vermilion and yellow on the back of the neck; tail green in the middle, with more or less yellow on the sides. They live in large flocks, moving from place to place in search of the newly expanded flowers of the gum trees (*eucalypti*); they are sometimes caged, but do not live long in confinement from the difficulty of supplying them with proper food; they have been seen frequently to put out their tongues to painted and artificial flowers as if in search of their favorite pollen. Some of the species are small, like the orange-winged paroquet (*T. pyrrhopterus*, Lath.) of the Sandwich Islands; this is 7½ inches long, with pale pinkish bill, general color green, with under wing coverts rich orange, and the sides of the neck and throat grayish white. They are active, familiar, docile, and very affectionate toward each other whether free or confined; their gait and quick flight are much as in perching birds; the voice is not disagreeable, resembling the chirp of a sparrow.—Other less known genera are *coracopsis* (Wagl.), from Madagascar and S. Africa; and *prioniturus* (Wagl.), from the Philippine islands, of which the racket-tailed

paroquet (*P. platurus*, Wagl.), the only species described by Gray, has the 2 middle tail feathers prolonged beyond the others, with the shafts bare of webs except at the tips.

PAROS, or PARO, an island in the *Ægean* sea, one of the Cyclades, separated from Naxos or Naxia on the E. by a strait 5 m. wide; length N. E. and S. W. 14 m., breadth 11 m.; pop. about 6,000. Its highest point of land, Mount St. Elias, stands in lat. $37^{\circ} 2' 46''$ N., long. $25^{\circ} 11' 30''$ E. There are several harbors, Parikia on the W., St. Maria, Marmora, and Trio on the E., and Naussa on the N., the best in the archipelago. There are also several villages, of which the principal is Paroikia, on the site of the ancient Paros. The country, though hilly, is fertile, and produces principally olives and cotton, and also corn, wine, fruit, and legumes. It was in former times chiefly renowned for its marble, which was remarkably white and durable, and was considered second only to that of Pentelicus. The principal quarries were in Mount Marpessa, but since the fall of the eastern empire these have been neglected.—Paros, according to tradition, was first inhabited by Oretans and Arcadians, and obtained its name from Parus, a son of the Arcadian Parrhasius. It was however early colonized by the Ionians, and by means of its maritime trade became so prosperous that it in turn colonized Thasus, Parium on the Propontis, and Pharos on the Illyrian coast. Having submitted to the Persians after the battle of Marathon (490 B. C.), it was enabled to bid defiance to Miltiades, and after the sea fight of Salamis (480) secured its safety by paying a fine to Themistocles. Subsequently it fell into the power of Athens, along with the other islands of the *Ægean*, and paid to that city a tribute of 19,440 drachmas yearly. In later times it became subject to Venice, constituting for a time a portion of the dukedom of Naxos; but subsequently it came into the possession of the Venetian family of Veniero, and in the 16th century was taken by Barbarossa. Toward the close of the 18th it became a

naval station for the Russian fleet, and now forms a part of the kingdom of Greece.

PAROTID GLAND (Gr. *πάρα*, near, and *οὖρον*, ear), the largest of the salivary glands, situated in man on the side of the face, in the deep hollow between the posterior border of the lower jaw, the ear, and the mastoid process of the temporal bone, and extending from the zygomatic arch to the angle of the jaw. It is irregularly pyramidal in shape, the base turned outward, and its external surface is just underneath the skin. The structure is firm, of a grayish white color, made up of granular follicles, united into lobules and irregular lobes by dense areolar tissue; the ultimate follicles are very small, the average diameter being about $\frac{1}{15}$ of an inch, and are closely surrounded by a plexus of capillaries; their development begins from a simple canal opening from the mouth, sending off bud-like processes during growth. Its large single excretory tube, called Steno's duct, is about a line in diameter, directed horizontally forward, piercing the buccinator muscle, and opening into the mouth on a level with the 2d upper molar tooth. Its vessels are derived from branches of the external carotid artery, and its nerves from the facial, trifacial, and the cervical plexus. Its secretion is as thin and limpid as water, containing from $\frac{1}{4}$ to $\frac{1}{2}$ of 1 per cent. of solid matter; it resembles that from the sublingual gland, and from these two flows most of the saliva during mastication, favoring the mechanical reduction of the food by saturating it with watery fluid. It is subject to tumors, which, from the depth of the posterior portion and its relation to large vessels and nerves, it is difficult and often dangerous to remove. The common disease of children known as mumps is situated in this and in the submaxillary salivary gland. It is large in such mammals as masticate their food, as the horse, ruminants, pachyderms, and rodents; it is small in the carnivora, rudimentary in seals, and absent in carnivorous cetaceans.
